GDAL is an excellent open source geospatial library that has support for reading most vector and raster spatial data formats. Currently, GeoDjango only supports GDAL's vector data capabilities². GEOS and PROJ should be installed prior to building GDAL.

First download the latest GDAL release version and untar the archive:

```
$ wget https://download.osgeo.org/gdal/X.Y.Z/gdal-X.Y.Z.tar.gz
$ tar xzf gdal-X.Y.Z.tar.gz
```

For GDAL 3.6.x and greater, releases only support builds using CMake. To build with CMake create a build folder in the GDAL directory, and step into it:

```
$ cd gdal-X.Y.Z
$ mkdir build
$ cd build
```

Finally, configure, make and install GDAL:

```
$ cmake ..
$ cmake --build .
$ sudo cmake --build . --target install
```

If you have any problems, please see the troubleshooting section below for suggestions and solutions.

² Specifically, GeoDjango provides support for the OGR library, a component of GDAL.

Troubleshooting

Can't find GDAL library

When GeoDjango can't find the GDAL library, configure your [Library environment settings](#) or set `GDAL_LIBRARY_PATH` in your settings.

`GDAL_LIBRARY_PATH`

If your GDAL library is in a non-standard location, or you don't want to modify the system's library path then the `GDAL_LIBRARY_PATH` setting may be added to your Django settings file with the full path to the GDAL library. For example:

```
GDAL_LIBRARY_PATH = '/home/sue/local/lib/libgdal.so'
```

Database installation

Installing PostGIS

PostGIS adds geographic object support to PostgreSQL, turning it into a spatial database. [GEOS](#), [PROJ](#) and [GDAL](#) should be installed prior to building PostGIS. You might also need additional libraries, see [PostGIS requirements](#).

The [psycopg](#) or [psycopg2](#) module is required for use as the database adapter when using GeoDjango with PostGIS.

On Debian/Ubuntu, you are advised to install the following packages: `postgresql-x`, `postgresql-x-postgis-3`, `postgresql-server-dev-x`, and `python3-psycopg3` (x matching the PostgreSQL version you want to install). Alternately, you can [build from source](#). Consult the platform-specific instructions if you are on [macOS](#) or [Windows](#).

Support for psycopg 3.1.8+ was added.

Post-installation

Creating a spatial database

PostGIS 2 includes an extension for PostgreSQL that's used to enable spatial functionality:

```
$ createdb <db name>
$ psql <db name>
> CREATE EXTENSION postgis;
```

The database user must be a superuser in order to run `CREATE EXTENSION postgis;`. The command is run during the *migrate* process. An alternative is to use a migration operation in your project:

```
from django.contrib.postgres.operations import CreateExtension
from django.db import migrations

class Migration(migrations.Migration):
    operations = [CreateExtension("postgis"), ...]
```

If you plan to use PostGIS raster functionality on PostGIS 3+, you should also activate the `postgis_raster` extension. You can install the extension using the *CreateExtension* migration operation, or directly by running `CREATE EXTENSION postgis_raster;`.

GeoDjango does not currently leverage any *PostGIS topology functionality*. If you plan to use those features at some point, you can also install the `postgis_topology` extension by issuing `CREATE EXTENSION postgis_topology;`.

Managing the database

To administer the database, you can either use the pgAdmin III program (Start • PostgreSQL X • pgAdmin III) or the SQL Shell (Start • PostgreSQL X • SQL Shell). For example, to create a `geodjango` spatial database and user, the following may be executed from the SQL Shell as the `postgres` user:

```
postgres# CREATE USER geodjango PASSWORD 'my_passwd';
postgres# CREATE DATABASE geodjango OWNER geodjango;
```

Installing SpatiaLite

SpatiaLite adds spatial support to SQLite, turning it into a full-featured spatial database.

First, check if you can install SpatiaLite from system packages or binaries.

For example, on Debian-based distributions that package SpatiaLite 4.3+, try to install the `libsqlite3-mod-spatialite` package. For older releases install `spatialite-bin`.

For macOS, follow the [instructions below](#).

For Windows, you may find binaries on the [Gaia-SINS](#) home page.

In any case, you should always be able to [install from source](#).

Installing from source

GEOS and PROJ should be installed prior to building SpatiaLite.

SQLite

Check first if SQLite is compiled with the [R*Tree module](#). Run the sqlite3 command line interface and enter the following query:

```
sqlite> CREATE VIRTUAL TABLE testrtree USING rtree(id,minX,maxX,minY,maxY);
```

If you obtain an error, you will have to recompile SQLite from source. Otherwise, skip this section.

To install from sources, download the latest amalgamation source archive from the [SQLite download page](#), and extract:

```
$ wget https://www.sqlite.org/YYYY/sqlite-amalgamation-XXX0000.zip
$ unzip sqlite-amalgamation-XXX0000.zip
$ cd sqlite-amalgamation-XXX0000
```

Next, run the configure script –however the CFLAGS environment variable needs to be customized so that SQLite knows to build the R*Tree module:

```
$ CFLAGS="-DSQLITE_ENABLE_RTREE=1" ./configure
$ make
$ sudo make install
$ cd ..
```

SpatiaLite library (libspatialite)

Get the latest SpatiaLite library source bundle from the [download page](#):

```
$ wget https://www.gaia-gis.it/gaia-sins/libspatialite-sources/libspatialite-X.Y.Z.tar.gz
$ tar xaf libspatialite-X.Y.Z.tar.gz
$ cd libspatialite-X.Y.Z
$ ./configure
$ make
$ sudo make install
```

Note: For macOS users building from source, the SpatiaLite library and tools need to have their **target** configured:

```
$ ./configure --target=macosx
```

macOS-specific instructions

To install the SpatiaLite library and tools, macOS users can use [Homebrew](#).

Homebrew

[Homebrew](#) handles all the SpatiaLite related packages on your behalf, including SQLite, SpatiaLite, PROJ, and GEOS. Install them like this:

```
$ brew update
$ brew install spatialite-tools
$ brew install gdal
```

Finally, for GeoDjango to be able to find the SpatiaLite library, add the following to your `settings.py`:

```
SPATIALITE_LIBRARY_PATH = "/usr/local/lib/mod_spatialite.dylib"
```

DATABASES configuration

Set the [ENGINE](#) setting to one of the [spatial backends](#).

Add `django.contrib.gis` to `INSTALLED_APPS`

Like other Django contrib applications, you will only need to add `django.contrib.gis` to `INSTALLED_APPS` in your settings. This is so that the `gis` templates can be located –if not done, then features such as the geographic admin or KML sitemaps will not function properly.

Troubleshooting

If you can't find the solution to your problem here then participate in the community! You can:

- Join the `#django-geo` IRC channel on Libera.Chat. Please be patient and polite –while you may not get an immediate response, someone will attempt to answer your question as soon as they see it.
- Ask your question on the [GeoDjango](#) forum.
- File a ticket on the [Django trac](#) if you think there's a bug. Make sure to provide a complete description of the problem, versions used, and specify the component as “GIS” .

Library environment settings

By far, the most common problem when installing GeoDjango is that the external shared libraries (e.g., for GEOS and GDAL) cannot be located.¹ Typically, the cause of this problem is that the operating system isn't aware of the directory where the libraries built from source were installed.

In general, the library path may be set on a per-user basis by setting an environment variable, or by configuring the library path for the entire system.

LD_LIBRARY_PATH environment variable

A user may set this environment variable to customize the library paths they want to use. The typical library directory for software built from source is `/usr/local/lib`. Thus, `/usr/local/lib` needs to be included in the `LD_LIBRARY_PATH` variable. For example, the user could place the following in their bash profile:

```
export LD_LIBRARY_PATH=/usr/local/lib
```

Setting system library path

On GNU/Linux systems, there is typically a file in `/etc/ld.so.conf`, which may include additional paths from files in another directory, such as `/etc/ld.so.conf.d`. As the root user, add the custom library path (like `/usr/local/lib`) on a new line in `ld.so.conf`. This is one example of how to do so:

```
$ sudo echo /usr/local/lib >> /etc/ld.so.conf
$ sudo ldconfig
```

For OpenSolaris users, the system library path may be modified using the `crle` utility. Run `crle` with no options to see the current configuration and use `crle -l` to set with the new library path. Be very careful when modifying the system library path:

```
# crle -l $OLD_PATH:/usr/local/lib
```

Install binutils

GeoDjango uses the `find_library` function (from the `ctypes.util` Python module) to discover libraries. The `find_library` routine uses a program called `objdump` (part of the `binutils` package) to verify a shared library on GNU/Linux systems. Thus, if `binutils` is not installed on your Linux system then Python's `ctypes` may not be able to find your library even if your library path is set correctly and geospatial libraries were built perfectly.

The `binutils` package may be installed on Debian and Ubuntu systems using the following command:

¹ GeoDjango uses the `find_library()` routine from `ctypes.util` to locate shared libraries.

```
$ sudo apt-get install binutils
```

Similarly, on Red Hat and CentOS systems:

```
$ sudo yum install binutils
```

Platform-specific instructions

macOS

Because of the variety of packaging systems available for macOS, users have several different options for installing GeoDjango. These options are:

- [Postgres.app](#) (easiest and recommended)
- [Homebrew](#)
- [Fink](#)
- [MacPorts](#)
- [Building from source](#)

This section also includes instructions for installing an upgraded version of [Python](#) from packages provided by the Python Software Foundation, however, this is not required.

Python

Although macOS comes with Python installed, users can use [framework installers](#) provided by the Python Software Foundation. An advantage to using the installer is that macOS’ s Python will remain “pristine” for internal operating system use.

Note: You will need to modify the `PATH` environment variable in your `.profile` file so that the new version of Python is used when `python` is entered at the command-line:

```
export PATH=/Library/Frameworks/Python.framework/Versions/Current/bin:$PATH
```

Postgres.app

[Postgres.app](#) is a standalone PostgreSQL server that includes the PostGIS extension. You will also need to install `gdal` and `libgeoip` with [Homebrew](#).

After installing `Postgres.app`, add the following to your `.bash_profile` so you can run the package's programs from the command-line. Replace `X.Y` with the version of PostgreSQL in the `Postgres.app` you installed:

```
export PATH=$PATH:/Applications/Postgres.app/Contents/Versions/X.Y/bin
```

You can check if the path is set up correctly by typing `which psql` at a terminal prompt.

Homebrew

[Homebrew](#) provides “recipes” for building binaries and packages from source. It provides recipes for the GeoDjango prerequisites on Macintosh computers running macOS. Because Homebrew still builds the software from source, [Xcode](#) is required.

Summary:

```
$ brew install postgresql
$ brew install postgis
$ brew install gdal
$ brew install libgeoip
```

Fink

[Kurt Schwehr](#) has been gracious enough to create GeoDjango packages for users of the [Fink](#) package system. [Different packages are available](#) (starting with `django-gis`), depending on which version of Python you want to use.

MacPorts

[MacPorts](#) may be used to install GeoDjango prerequisites on computers running macOS. Because MacPorts still builds the software from source, [Xcode](#) is required.

Summary:

```
$ sudo port install postgresql13-server
$ sudo port install geos
$ sudo port install proj6
$ sudo port install postgis3
```

(continues on next page)

(continued from previous page)

```
$ sudo port install gdal
$ sudo port install libgeoip
```

Note: You will also have to modify the PATH in your .profile so that the MacPorts programs are accessible from the command-line:

```
export PATH=/opt/local/bin:/opt/local/lib/postgresql13/bin
```

In addition, add the DYLD_FALLBACK_LIBRARY_PATH setting so that the libraries can be found by Python:

```
export DYLD_FALLBACK_LIBRARY_PATH=/opt/local/lib:/opt/local/lib/postgresql13
```

Windows

Proceed through the following sections sequentially in order to install GeoDjango on Windows. In this tutorial we will install 64 bit versions of each application.

Python

Install a 64 bit version of Python. See [Install Python](#) for further information.

PostgreSQL

Download the latest [PostgreSQL 15.x installer](#) from the [EnterpriseDB](#) website. After downloading, run the installer, follow the on-screen directions, and keep the default options unless you know the consequences of changing them.

Note: The PostgreSQL installer creates a new `postgres` database superuser. You will be prompted once to set the password –make sure to remember it!

When the installer completes, it will ask to “Launch Stack Builder at exit?” –keep this checked, as it is necessary to install [PostGIS](#).

Note: If installed successfully, the PostgreSQL server will run in the background each time the system is started as a Windows service. A PostgreSQL 15 start menu group will be created and contains shortcuts for the Application Stack Builder (ASB) as well as the ‘SQL Shell’, which will launch a `psql` command window.

PostGIS

From within the Stack Builder (to run outside of the installer, Start • PostgreSQL 15 • Application Stack Builder), select PostgreSQL 15 (x64) on port 5432 from the drop down menu and click next. Expand the Categories • Spatial Extensions menu tree and select PostGIS X.Y for PostgreSQL 15.

After clicking next, you will be prompted to confirm the selected package and “Download directory” . Click next again, this will download PostGIS and you will be asked to click next to begin the PostGIS installer. Select the default options during install. The install process includes four Yes/No dialog boxes, the default option for all four is “No” .

OSGeo4W

The [OSGeo4W installer](#) helps to install the PROJ, GDAL, and GEOS libraries required by GeoDjango. First, download the [OSGeo4W installer](#), and run it. Select Express Web-GIS Install and click next. In the ‘Select Packages’ list, ensure that GDAL is selected. If any other packages are enabled by default, they are not required by GeoDjango and may be unchecked safely. After clicking next and accepting the license agreements, the packages will be automatically downloaded and installed, after which you may exit the installer.

Modify Windows environment

In order to use GeoDjango, you will need to add your OSGeo4W directories to your Windows system Path, as well as create GDAL_DATA and PROJ_LIB environment variables. The following set of commands, executable with `cmd.exe`, will set this up. Restart your device once this is complete for new environment variables to be recognized:

```
set OSGEO4W_ROOT=C:\OSGeo4W
set GDAL_DATA=%OSGEO4W_ROOT%\apps\gdal\share\gdal
set PROJ_LIB=%OSGEO4W_ROOT%\share\proj
set PATH=%PATH%;%OSGEO4W_ROOT%\bin
reg ADD "HKLM\SYSTEM\CurrentControlSet\Control\Session Manager\Environment" /v Path /t REG_EXPAND_SZ /f /d "%PATH%"
reg ADD "HKLM\SYSTEM\CurrentControlSet\Control\Session Manager\Environment" /v GDAL_DATA /t REG_EXPAND_SZ /f /d "%GDAL_DATA%"
reg ADD "HKLM\SYSTEM\CurrentControlSet\Control\Session Manager\Environment" /v PROJ_LIB /t REG_EXPAND_SZ /f /d "%PROJ_LIB%"
```

Note: Administrator privileges are required to execute these commands. To do this, run command prompt as administrator and enter the commands above. You need to log out and log back in again for the settings to take effect.

Note: If you customized the OSGeo4W installation directories, then you will need to modify the `OSGEO4W_ROOT` variables accordingly.

Install Django and set up database

Install Django on your system. It is recommended that you create a [virtual environment](#) for each project you create.

psycopyg

The `psycopyg` Python module provides the interface between Python and the PostgreSQL database. `psycopyg` can be installed via pip within your Python virtual environment:

```
...> py -m pip install psycopyg
```

GeoDjango Model API

This document explores the details of the GeoDjango Model API. Throughout this section, we' ll be using the following geographic model of a [ZIP code](#) and of a [Digital Elevation Model](#) as our examples:

```
from django.contrib.gis.db import models

class Zipcode(models.Model):
    code = models.CharField(max_length=5)
    poly = models.PolygonField()

class Elevation(models.Model):
    name = models.CharField(max_length=100)
    rast = models.RasterField()
```

Spatial Field Types

Spatial fields consist of a series of geometry field types and one raster field type. Each of the geometry field types correspond to the OpenGIS Simple Features specification¹. There is no such standard for raster data.

GeometryField

```
class GeometryField
```

The base class for geometry fields.

PointField

```
class PointField
```

Stores a *Point*.

LineStringField

```
class LineStringField
```

Stores a *LineString*.

PolygonField

```
class PolygonField
```

Stores a *Polygon*.

MultiPointField

```
class MultiPointField
```

Stores a *MultiPoint*.

¹ OpenGIS Consortium, Inc., Simple Feature Specification For SQL.

MultiLineStringField

```
class MultiLineStringField
```

Stores a *MultiLineString*.

MultiPolygonField

```
class MultiPolygonField
```

Stores a *MultiPolygon*.

GeometryCollectionField

```
class GeometryCollectionField
```

Stores a *GeometryCollection*.

RasterField

```
class RasterField
```

Stores a *GDALRaster*.

`RasterField` is currently only implemented for the PostGIS backend.

Spatial Field Options

In addition to the regular [Field options](#) available for Django model fields, spatial fields have the following additional options. All are optional.

`srid`

`BaseSpatialField.srid`

Sets the SRID² (Spatial Reference System Identity) of the geometry field to the given value. Defaults to 4326 (also known as [WGS84](#), units are in degrees of longitude and latitude).

² See [id.](#) at Ch. 2.3.8, p. 39 (Geometry Values and Spatial Reference Systems).

Selecting an SRID

Choosing an appropriate SRID for your model is an important decision that the developer should consider carefully. The SRID is an integer specifier that corresponds to the projection system that will be used to interpret the data in the spatial database.³ Projection systems give the context to the coordinates that specify a location. Although the details of [geodesy](#) are beyond the scope of this documentation, the general problem is that the earth is spherical and representations of the earth (e.g., paper maps, web maps) are not.

Most people are familiar with using latitude and longitude to reference a location on the earth's surface. However, latitude and longitude are angles, not distances. In other words, while the shortest path between two points on a flat surface is a straight line, the shortest path between two points on a curved surface (such as the earth) is an arc of a [great circle](#).⁴ Thus, additional computation is required to obtain distances in planar units (e.g., kilometers and miles). Using a geographic coordinate system may introduce complications for the developer later on. For example, SpatiaLite does not have the capability to perform distance calculations between geometries using geographic coordinate systems, e.g. constructing a query to find all points within 5 miles of a county boundary stored as WGS84.⁵

Portions of the earth's surface may be projected onto a two-dimensional, or Cartesian, plane. Projected coordinate systems are especially convenient for region-specific applications, e.g., if you know that your database will only cover geometries in [North Kansas](#), then you may consider using a projection system specific to that region. Moreover, projected coordinate systems are defined in Cartesian units (such as meters or feet), easing distance calculations.

Note: If you wish to perform arbitrary distance queries using non-point geometries in WGS84 in PostGIS and you want decent performance, enable the `GeometryField.geography` keyword so that [geography database type](#) is used instead.

Additional Resources:

- [spatialreference.org](#): A Django-powered database of spatial reference systems.
- [The State Plane Coordinate System](#): A website covering the various projection systems used in the United States. Much of the U.S. spatial data encountered will be in one of these coordinate systems rather than in a geographic coordinate system such as WGS84.

³ Typically, SRID integer corresponds to an EPSG ([European Petroleum Survey Group](#)) identifier. However, it may also be associated with custom projections defined in spatial database's spatial reference systems table.

⁴ Terry A. Slocum, Robert B. McMaster, Fritz C. Kessler, & Hugh H. Howard, *Thematic Cartography and Geographic Visualization* (Prentice Hall, 2nd edition), at Ch. 7.1.3.

⁵ This limitation does not apply to PostGIS.

`spatial_index`

`BaseSpatialField.spatial_index`

Defaults to `True`. Creates a spatial index for the given geometry field.

Note: This is different from the `db_index` field option because spatial indexes are created in a different manner than regular database indexes. Specifically, spatial indexes are typically created using a variant of the R-Tree, while regular database indexes typically use B-Trees.

Geometry Field Options

There are additional options available for Geometry fields. All the following options are optional.

`dim`

`GeometryField.dim`

This option may be used for customizing the coordinate dimension of the geometry field. By default, it is set to 2, for representing two-dimensional geometries. For spatial backends that support it, it may be set to 3 for three-dimensional support.

Note: At this time 3D support is limited to the PostGIS and SpatiaLite backends.

`geography`

`GeometryField.geography`

If set to `True`, this option will create a database column of type geography, rather than geometry. Please refer to the [geography type](#) section below for more details.

Note: Geography support is limited to PostGIS and will force the SRID to be 4326.

Geography Type

The geography type provides native support for spatial features represented with geographic coordinates (e.g., WGS84 longitude/latitude).⁶ Unlike the plane used by a geometry type, the geography type uses a spherical representation of its data. Distance and measurement operations performed on a geography column automatically employ great circle arc calculations and return linear units. In other words, when `ST_Distance` is called on two geographies, a value in meters is returned (as opposed to degrees if called on a geometry column in WGS84).

Because geography calculations involve more mathematics, only a subset of the PostGIS spatial lookups are available for the geography type. Practically, this means that in addition to the [distance lookups](#) only the following additional [spatial lookups](#) are available for geography columns:

- `bboverlaps`
- `coveredby`
- `covers`
- `intersects`

If you need to use a spatial lookup or aggregate that doesn't support the geography type as input, you can use the `Cast` database function to convert the geography column to a geometry type in the query:

```
from django.contrib.gis.db.models import PointField
from django.db.models.functions import Cast

Zipcode.objects.annotate(geom=Cast("geography_field", PointField())).filter(
    geom__within=poly
)
```

For more information, the PostGIS documentation contains a helpful section on determining [when to use geography data type over geometry data type](#).

GeoDjango Database API

Spatial Backends

GeoDjango currently provides the following spatial database backends:

- `django.contrib.gis.db.backends.postgis`
- `django.contrib.gis.db.backends.mysql`
- `django.contrib.gis.db.backends.oracle`
- `django.contrib.gis.db.backends.spatialite`

⁶ Please refer to the [PostGIS Geography Type](#) documentation for more details.

MySQL Spatial Limitations

Django supports spatial functions operating on real geometries available in modern MySQL versions. However, the spatial functions are not as rich as other backends like PostGIS.

Raster Support

`RasterField` is currently only implemented for the PostGIS backend. Spatial lookups are available for raster fields, but spatial database functions and aggregates aren't implemented for raster fields.

Creating and Saving Models with Geometry Fields

Here is an example of how to create a geometry object (assuming the `Zipcode` model):

```
>>> from zipcode.models import Zipcode
>>> z = Zipcode(code=77096, poly="POLYGON(( 10 10, 10 20, 20 20, 20 15, 10 10)))"
>>> z.save()
```

`GEOSGeometry` objects may also be used to save geometric models:

```
>>> from django.contrib.gis.geos import GEOSGeometry
>>> poly = GEOSGeometry("POLYGON(( 10 10, 10 20, 20 20, 20 15, 10 10)))"
>>> z = Zipcode(code=77096, poly=poly)
>>> z.save()
```

Moreover, if the `GEOSGeometry` is in a different coordinate system (has a different SRID value) than that of the field, then it will be implicitly transformed into the SRID of the model's field, using the spatial database's transform procedure:

```
>>> poly_3084 = GEOSGeometry(
...     "POLYGON(( 10 10, 10 20, 20 20, 20 15, 10 10))", srid=3084
... ) # SRID 3084 is 'NAD83(HARN) / Texas Centric Lambert Conformal'
>>> z = Zipcode(code=78212, poly=poly_3084)
>>> z.save()
>>> from django.db import connection
>>> print(
...     connection.queries[-1]["sql"]
... ) # printing the last SQL statement executed (requires DEBUG=True)
INSERT INTO "geoapp_zipcode" ("code", "poly") VALUES (78212, ST_Transform(ST_GeomFromWKB('\001 ...
↪ ', 3084), 4326))
```

Thus, geometry parameters may be passed in using the `GEOSGeometry` object, WKT (Well Known Text¹),

¹ See Open Geospatial Consortium, Inc., [OpenGIS Simple Feature Specification For SQL](#), Document 99-049 (May 5, 1999), at Ch. 3.2.5, p. 3-11 (SQL Textual Representation of Geometry).

HEXEWKB (PostGIS specific –a WKB geometry in hexadecimal²), and GeoJSON (see [RFC 7946](#)). Essentially, if the input is not a `GEOSGeometry` object, the geometry field will attempt to create a `GEOSGeometry` instance from the input.

For more information creating *GEOSGeometry* objects, refer to the [GEOS tutorial](#).

Creating and Saving Models with Raster Fields

When creating raster models, the raster field will implicitly convert the input into a *GDALRaster* using lazy-evaluation. The raster field will therefore accept any input that is accepted by the *GDALRaster* constructor.

Here is an example of how to create a raster object from a raster file `volcano.tif` (assuming the Elevation model):

```
>>> from elevation.models import Elevation
>>> dem = Elevation(name="Volcano", rast="/path/to/raster/volcano.tif")
>>> dem.save()
```

GDALRaster objects may also be used to save raster models:

```
>>> from django.contrib.gis.gdal import GDALRaster
>>> rast = GDALRaster(
...     {
...         "width": 10,
...         "height": 10,
...         "name": "Canyon",
...         "srid": 4326,
...         "scale": [0.1, -0.1],
...         "bands": [{"data": range(100)}],
...     }
... )
>>> dem = Elevation(name="Canyon", rast=rast)
>>> dem.save()
```

Note that this equivalent to:

```
>>> dem = Elevation.objects.create(
...     name="Canyon",
...     rast={
...         "width": 10,
...         "height": 10,
...         "name": "Canyon",
...         "srid": 4326,
...         "scale": [0.1, -0.1],
...     },
... )
```

(continues on next page)

² See PostGIS EWKB, EWKT and Canonical Forms, PostGIS documentation at Ch. 4.1.2.

(continued from previous page)

```
...         "bands": [{"data": range(100)}],
...     },
... )
```

Spatial Lookups

GeoDjango's lookup types may be used with any manager method like `filter()`, `exclude()`, etc. However, the lookup types unique to GeoDjango are only available on spatial fields.

Filters on 'normal' fields (e.g. *CharField*) may be chained with those on geographic fields. Geographic lookups accept geometry and raster input on both sides and input types can be mixed freely.

The general structure of geographic lookups is described below. A complete reference can be found in the [spatial lookup reference](#).

Geometry Lookups

Geographic queries with geometries take the following general form (assuming the `Zipcode` model used in the [GeoDjango Model API](#)):

```
>>> qs = Zipcode.objects.filter(<field>__<lookup_type>=<parameter>)
>>> qs = Zipcode.objects.exclude(...)
```

For example:

```
>>> qs = Zipcode.objects.filter(poly__contains=pnt)
>>> qs = Elevation.objects.filter(poly__contains=rst)
```

In this case, `poly` is the geographic field, *contains* is the spatial lookup type, `pnt` is the parameter (which may be a *GEOSGeometry* object or a string of GeoJSON, WKT, or HEXEWKB), and `rst` is a *GDALRaster* object.

Raster Lookups

The raster lookup syntax is similar to the syntax for geometries. The only difference is that a band index can be specified as additional input. If no band index is specified, the first band is used by default (index 0). In that case the syntax is identical to the syntax for geometry lookups.

To specify the band index, an additional parameter can be specified on both sides of the lookup. On the left hand side, the double underscore syntax is used to pass a band index. On the right hand side, a tuple of the raster and band index can be specified.

This results in the following general form for lookups involving rasters (assuming the `Elevation` model used in the [GeoDjango Model API](#)):

```
>>> qs = Elevation.objects.filter(<field>__<lookup_type>=<parameter>)
>>> qs = Elevation.objects.filter(<field>__<band_index>__<lookup_type>=<parameter>)
>>> qs = Elevation.objects.filter(<field>__<lookup_type>=(<raster_input>, <band_index>))
```

For example:

```
>>> qs = Elevation.objects.filter(rast__contains=geom)
>>> qs = Elevation.objects.filter(rast__contains=rst)
>>> qs = Elevation.objects.filter(rast__1__contains=geom)
>>> qs = Elevation.objects.filter(rast__contains=(rst, 1))
>>> qs = Elevation.objects.filter(rast__1__contains=(rst, 1))
```

On the left hand side of the example, `rast` is the geographic raster field and `contains` is the spatial lookup type. On the right hand side, `geom` is a geometry input and `rst` is a *GDALRaster* object. The band index defaults to 0 in the first two queries and is set to 1 on the others.

While all spatial lookups can be used with raster objects on both sides, not all underlying operators natively accept raster input. For cases where the operator expects geometry input, the raster is automatically converted to a geometry. It's important to keep this in mind when interpreting the lookup results.

The type of raster support is listed for all lookups in the [compatibility table](#). Lookups involving rasters are currently only available for the PostGIS backend.

Distance Queries

Introduction

Distance calculations with spatial data is tricky because, unfortunately, the Earth is not flat. Some distance queries with fields in a geographic coordinate system may have to be expressed differently because of limitations in PostGIS. Please see the [Selecting an SRID](#) section in the [GeoDjango Model API](#) documentation for more details.

Distance Lookups

Availability: PostGIS, MariaDB, MySQL, Oracle, SpatiaLite, PGRaster (Native)

The following distance lookups are available:

- `distance_lt`
- `distance_lte`
- `distance_gt`
- `distance_gte`

- *dwithin* (except MariaDB and MySQL)

Note: For measuring, rather than querying on distances, use the *Distance* function.

Distance lookups take a tuple parameter comprising:

1. A geometry or raster to base calculations from; and
2. A number or *Distance* object containing the distance.

If a *Distance* object is used, it may be expressed in any units (the SQL generated will use units converted to those of the field); otherwise, numeric parameters are assumed to be in the units of the field.

Note: In PostGIS, `ST_Distance_Sphere` does not limit the geometry types geographic distance queries are performed with.³ However, these queries may take a long time, as great-circle distances must be calculated on the fly for every row in the query. This is because the spatial index on traditional geometry fields cannot be used.

For much better performance on WGS84 distance queries, consider using *geography* columns in your database instead because they are able to use their spatial index in distance queries. You can tell GeoDjango to use a geography column by setting `geography=True` in your field definition.

For example, let's say we have a `SouthTexasCity` model (from the *GeoDjango distance tests*) on a projected coordinate system valid for cities in southern Texas:

```
from django.contrib.gis.db import models

class SouthTexasCity(models.Model):
    name = models.CharField(max_length=30)
    # A projected coordinate system (only valid for South Texas!)
    # is used, units are in meters.
    point = models.PointField(srid=32140)
```

Then distance queries may be performed as follows:

```
>>> from django.contrib.gis.geos import GEOSGeometry
>>> from django.contrib.gis.measure import D # ``D`` is a shortcut for ``Distance``
>>> from geoapp.models import SouthTexasCity
# Distances will be calculated from this point, which does not have to be projected.
>>> pnt = GEOSGeometry("POINT(-96.876369 29.905320)", srid=4326)
# If numeric parameter, units of field (meters in this case) are assumed.
```

(continues on next page)

³ See *PostGIS documentation* on `ST_DistanceSphere`.

(continued from previous page)

```
>>> qs = SouthTexasCity.objects.filter(point__distance_lte=(pnt, 7000))
# Find all Cities within 7 km, > 20 miles away, and > 100 chains away (an obscure unit)
>>> qs = SouthTexasCity.objects.filter(point__distance_lte=(pnt, D(km=7)))
>>> qs = SouthTexasCity.objects.filter(point__distance_gte=(pnt, D(mi=20)))
>>> qs = SouthTexasCity.objects.filter(point__distance_gte=(pnt, D(chain=100)))
```

Raster queries work the same way by replacing the geometry field `point` with a raster field, or the `pnt` object with a raster object, or both. To specify the band index of a raster input on the right hand side, a 3-tuple can be passed to the lookup as follows:

```
>>> qs = SouthTexasCity.objects.filter(point__distance_gte=(rst, 2, D(km=7)))
```

Where the band with index 2 (the third band) of the raster `rst` would be used for the lookup.

Compatibility Tables

Spatial Lookups

The following table provides a summary of what spatial lookups are available for each spatial database backend. The PostGIS Raster (PGRaster) lookups are divided into the three categories described in the [raster lookup details](#): native support N, bilateral native support B, and geometry conversion support C.

Lookup Type	PostGIS	Oracle	MariaDB	MySQL Page 1142, 4	Spatialite	PGRaster
<i>bbcontains</i>	X		X	X	X	N
<i>bboverlaps</i>	X		X	X	X	N
<i>contained</i>	X		X	X	X	N
<i>contains</i>	X	X	X	X	X	B
<i>contains_properly</i>	X					B
<i>coveredby</i>	X	X			X	B
<i>covers</i>	X	X			X	B
<i>crosses</i>	X		X	X	X	C
<i>disjoint</i>	X	X	X	X	X	B
<i>distance_gt</i>	X	X	X	X	X	N
<i>distance_gte</i>	X	X	X	X	X	N
<i>distance_lt</i>	X	X	X	X	X	N
<i>distance_lte</i>	X	X	X	X	X	N
<i>dwithin</i>	X	X			X	B
<i>equals</i>	X	X	X	X	X	C
<i>exact</i>	X	X	X	X	X	B
<i>intersects</i>	X	X	X	X	X	B

<i>SymDifference</i>	X	X	X	X	X
<i>Transform</i>	X	X			X
<i>Translate</i>	X				X
<i>Union</i>	X	X	X	X	X

Aggregate Functions

The following table provides a summary of what GIS-specific aggregate functions are available on each spatial backend. Please note that MySQL does not support any of these aggregates, and is thus excluded from the table.

Aggregate	PostGIS	Oracle	Spatialite
<i>Collect</i>	X		X
<i>Extent</i>	X	X	X
<i>Extent3D</i>	X		
<i>MakeLine</i>	X		X
<i>Union</i>	X	X	X

GeoDjango Forms API

GeoDjango provides some specialized form fields and widgets in order to visually display and edit geolocalized data on a map. By default, they use [OpenLayers](#)-powered maps, with a base WMS layer provided by [NASA](#).

Field arguments

In addition to the regular [form field arguments](#), GeoDjango form fields take the following optional arguments.

`srid`

`Field.srid`

This is the SRID code that the field value should be transformed to. For example, if the map widget SRID is different from the SRID more generally used by your application or database, the field will automatically convert input values into that SRID.

`geom_type`

`Field.geom_type`

You generally shouldn't have to set or change that attribute which should be set up depending on the field class. It matches the OpenGIS standard geometry name.

Form field classes

`GeometryField`

```
class GeometryField
```

`PointField`

```
class PointField
```

`LineStringField`

```
class LineStringField
```

`PolygonField`

```
class PolygonField
```

`MultiPointField`

```
class MultiPointField
```

`MultiLineStringField`

```
class MultiLineStringField
```

`MultiPolygonField`

```
class MultiPolygonField
```

`GeometryCollectionField`

```
class GeometryCollectionField
```

Form widgets

GeoDjango form widgets allow you to display and edit geographic data on a visual map. Note that none of the currently available widgets supports 3D geometries, hence geometry fields will fallback using a `Textarea` widget for such data.

Widget attributes

GeoDjango widgets are template-based, so their attributes are mostly different from other Django widget attributes.

`BaseGeometryWidget.geom_type`

The OpenGIS geometry type, generally set by the form field.

`BaseGeometryWidget.map_height`

`BaseGeometryWidget.map_width`

Height and width of the widget map (default is 400x600).

Deprecated since version 4.2: `map_height` and `map_width` attributes are deprecated, use CSS to size map widgets instead.

`BaseGeometryWidget.map_srid`

SRID code used by the map (default is 4326).

`BaseGeometryWidget.display_raw`

Boolean value specifying if a textarea input showing the serialized representation of the current geometry is visible, mainly for debugging purposes (default is `False`).

`BaseGeometryWidget.supports_3d`

Indicates if the widget supports edition of 3D data (default is `False`).

`BaseGeometryWidget.template_name`

The template used to render the map widget.

You can pass widget attributes in the same manner that for any other Django widget. For example:

```
from django.contrib.gis import forms

class MyGeoForm(forms.Form):
    point = forms.PointField(widget=forms.OSMWidget(attrs={"display_raw": True}))
```

Widget classes

`BaseGeometryWidget`

`class BaseGeometryWidget`

This is an abstract base widget containing the logic needed by subclasses. You cannot directly use this widget for a geometry field. Note that the rendering of GeoDjango widgets is based on a template, identified by the `template_name` class attribute.

`OpenLayersWidget`

`class OpenLayersWidget`

This is the default widget used by all GeoDjango form fields. `template_name` is `gis/openlayers.html`.

`OpenLayersWidget` and `OSMWidget` use the `ol.js` file hosted on the `cdn.jsdelivr.net` content-delivery network. You can subclass these widgets in order to specify your own version of the `ol.js` file in the `js` property of the inner `Media` class (see [Assets as a static definition](#)).

OSMWidget

class OSMWidget

This widget uses an OpenStreetMap base layer to display geographic objects on. Attributes are:

template_name

gis/openlayers-osm.html

default_lat

default_lon

The default center latitude and longitude are 47 and 5, respectively, which is a location in eastern France.

default_zoom

The default map zoom is 12.

The *OpenLayersWidget* note about JavaScript file hosting above also applies here. See also this [FAQ answer](#) about https access to map tiles.

GIS QuerySet API Reference

Spatial Lookups

The spatial lookups in this section are available for *GeometryField* and *RasterField*.

For an introduction, see the [spatial lookups introduction](#). For an overview of what lookups are compatible with a particular spatial backend, refer to the [spatial lookup compatibility table](#).

Lookups with rasters

All examples in the reference below are given for geometry fields and inputs, but the lookups can be used the same way with rasters on both sides. Whenever a lookup doesn't support raster input, the input is automatically converted to a geometry where necessary using the *ST_Polygon* function. See also the [introduction to raster lookups](#).

The database operators used by the lookups can be divided into three categories:

- Native raster support N: the operator accepts rasters natively on both sides of the lookup, and raster input can be mixed with geometry inputs.
- Bilateral raster support B: the operator supports rasters only if both sides of the lookup receive raster inputs. Raster data is automatically converted to geometries for mixed lookups.
- Geometry conversion support C. The lookup does not have native raster support, all raster data is automatically converted to geometries.

The examples below show the SQL equivalent for the lookups in the different types of raster support. The same pattern applies to all spatial lookups.

Case	Lookup	SQL Equivalent
N, B	<code>rast__contains=rst</code>	<code>ST_Contains(rast, rst)</code>
N, B	<code>rast__1__contains=(rst, 2)</code>	<code>ST_Contains(rast, 1, rst, 2)</code>
B, C	<code>rast__contains=geom</code>	<code>ST_Contains(ST_Polygon(rast), geom)</code>
B, C	<code>rast__1__contains=geom</code>	<code>ST_Contains(ST_Polygon(rast, 1), geom)</code>
B, C	<code>poly__contains=rst</code>	<code>ST_Contains(poly, ST_Polygon(rst))</code>
B, C	<code>poly__contains=(rst, 1)</code>	<code>ST_Contains(poly, ST_Polygon(rst, 1))</code>
C	<code>rast__crosses=rst</code>	<code>ST_Crosses(ST_Polygon(rast), ST_Polygon(rst))</code>
C	<code>rast__1__crosses=(rst, 2)</code>	<code>ST_Crosses(ST_Polygon(rast, 1), ST_Polygon(rst, 2))</code>
C	<code>rast__crosses=geom</code>	<code>ST_Crosses(ST_Polygon(rast), geom)</code>
C	<code>poly__crosses=rst</code>	<code>ST_Crosses(poly, ST_Polygon(rst))</code>

Spatial lookups with rasters are only supported for PostGIS backends (denominated as PGRaster in this section).

`bbcontains`

Availability: [PostGIS](#), MariaDB, MySQL, SpatiaLite, PGRaster (Native)

Tests if the geometry or raster field' s bounding box completely contains the lookup geometry' s bounding box.

Example:

```
Zipcode.objects.filter(poly__bbcontains=geom)
```

Backend	SQL Equivalent
PostGIS	<code>poly ~ geom</code>
MariaDB	<code>MBRContains(poly, geom)</code>
MySQL	<code>MBRContains(poly, geom)</code>
SpatiaLite	<code>MbrContains(poly, geom)</code>

bboverlaps

Availability: [PostGIS](#), MariaDB, MySQL, SpatiaLite, PGRaster (Native)

Tests if the geometry field's bounding box overlaps the lookup geometry's bounding box.

Example:

```
Zipcode.objects.filter(poly__bboverlaps=geom)
```

Backend	SQL Equivalent
PostGIS	<code>poly && geom</code>
MariaDB	<code>MBROverlaps(poly, geom)</code>
MySQL	<code>MBROverlaps(poly, geom)</code>
SpatiaLite	<code>MbrOverlaps(poly, geom)</code>

contained

Availability: [PostGIS](#), MariaDB, MySQL, SpatiaLite, PGRaster (Native)

Tests if the geometry field's bounding box is completely contained by the lookup geometry's bounding box.

Example:

```
Zipcode.objects.filter(poly__contained=geom)
```

Backend	SQL Equivalent
PostGIS	<code>poly @ geom</code>
MariaDB	<code>MBRWithin(poly, geom)</code>
MySQL	<code>MBRWithin(poly, geom)</code>
SpatiaLite	<code>MbrWithin(poly, geom)</code>

`contains`

Availability: [PostGIS](#), Oracle, MariaDB, MySQL, SpatiaLite, PGRaster (Bilateral)

Tests if the geometry field spatially contains the lookup geometry.

Example:

```
Zipcode.objects.filter(poly__contains=geom)
```

Backend	SQL Equivalent
PostGIS	<code>ST_Contains(poly, geom)</code>
Oracle	<code>SDO_CONTAINS(poly, geom)</code>
MariaDB	<code>ST_Contains(poly, geom)</code>
MySQL	<code>ST_Contains(poly, geom)</code>
SpatiaLite	<code>Contains(poly, geom)</code>

`contains_properly`

Availability: [PostGIS](#), PGRaster (Bilateral)

Returns true if the lookup geometry intersects the interior of the geometry field, but not the boundary (or exterior).

Example:

```
Zipcode.objects.filter(poly__contains_properly=geom)
```

Backend	SQL Equivalent
PostGIS	<code>ST_ContainsProperly(poly, geom)</code>

`coveredby`

Availability: [PostGIS](#), Oracle, PGRaster (Bilateral), SpatiaLite

Tests if no point in the geometry field is outside the lookup geometry.³

Example:

³ For an explanation of this routine, read [Quirks of the “Contains” Spatial Predicate](#) by Martin Davis (a PostGIS developer).

```
Zipcode.objects.filter(poly__coveredby=geom)
```

Backend	SQL Equivalent
PostGIS	ST_CoveredBy(poly, geom)
Oracle	SDO_COVEREDBY(poly, geom)
Spatialite	CoveredBy(poly, geom)

`covers`

Availability: [PostGIS](#), Oracle, PGRaster (Bilateral), Spatialite

Tests if no point in the lookup geometry is outside the geometry field.^{[Page 1150, 3](#)}

Example:

```
Zipcode.objects.filter(poly__covers=geom)
```

Backend	SQL Equivalent
PostGIS	ST_Covers(poly, geom)
Oracle	SDO_COVERS(poly, geom)
Spatialite	Covers(poly, geom)

`crosses`

Availability: [PostGIS](#), MariaDB, MySQL, Spatialite, PGRaster (Conversion)

Tests if the geometry field spatially crosses the lookup geometry.

Example:

```
Zipcode.objects.filter(poly__crosses=geom)
```

Backend	SQL Equivalent
PostGIS	ST_Crosses(poly, geom)
MariaDB	ST_Crosses(poly, geom)
MySQL	ST_Crosses(poly, geom)
Spatialite	Crosses(poly, geom)

`disjoint`

Availability: [PostGIS](#), Oracle, MariaDB, MySQL, SpatiaLite, PGRaster (Bilateral)

Tests if the geometry field is spatially disjoint from the lookup geometry.

Example:

```
Zipcode.objects.filter(poly__disjoint=geom)
```

Backend	SQL Equivalent
PostGIS	<code>ST_Disjoint(poly, geom)</code>
Oracle	<code>SDO_GEOM.RELATE(poly, 'DISJOINT', geom, 0.05)</code>
MariaDB	<code>ST_Disjoint(poly, geom)</code>
MySQL	<code>ST_Disjoint(poly, geom)</code>
SpatiaLite	<code>Disjoint(poly, geom)</code>

`equals`

Availability: [PostGIS](#), Oracle, MariaDB, MySQL, SpatiaLite, PGRaster (Conversion)

Tests if the geometry field is spatially equal to the lookup geometry.

Example:

```
Zipcode.objects.filter(poly__equals=geom)
```

Backend	SQL Equivalent
PostGIS	<code>ST_Equals(poly, geom)</code>
Oracle	<code>SDO_EQUAL(poly, geom)</code>
MariaDB	<code>ST_Equals(poly, geom)</code>
MySQL	<code>ST_Equals(poly, geom)</code>
SpatiaLite	<code>Equals(poly, geom)</code>

`exact, same_as`

Availability: [PostGIS](#), Oracle, MariaDB, MySQL, SpatiaLite, PGRaster (Bilateral)

Tests if the geometry field is “equal” to the lookup geometry. On Oracle, MySQL, and SpatiaLite, it tests spatial equality, while on PostGIS it tests equality of bounding boxes.

Example:

```
Zipcode.objects.filter(poly=geom)
```

Backend	SQL Equivalent
PostGIS	<code>poly ~= geom</code>
Oracle	<code>SDO_EQUAL(poly, geom)</code>
MariaDB	<code>ST_Equals(poly, geom)</code>
MySQL	<code>ST_Equals(poly, geom)</code>
SpatiaLite	<code>Equals(poly, geom)</code>

`intersects`

Availability: [PostGIS](#), Oracle, MariaDB, MySQL, SpatiaLite, PGRaster (Bilateral)

Tests if the geometry field spatially intersects the lookup geometry.

Example:

```
Zipcode.objects.filter(poly__intersects=geom)
```

Backend	SQL Equivalent
PostGIS	<code>ST_Intersects(poly, geom)</code>
Oracle	<code>SDO_OVERLAPBDYINTERSECT(poly, geom)</code>
MariaDB	<code>ST_Intersects(poly, geom)</code>
MySQL	<code>ST_Intersects(poly, geom)</code>
SpatiaLite	<code>Intersects(poly, geom)</code>

`isempty`

Availability: [PostGIS](#)

Tests if the geometry is empty.

Example:

```
Zipcode.objects.filter(poly__isempty=True)
```

`isvalid`

Availability: MySQL, [PostGIS](#), Oracle, SpatiaLite

Tests if the geometry is valid.

Example:

```
Zipcode.objects.filter(poly__isvalid=True)
```

Backend	SQL Equivalent
MySQL, PostGIS, SpatiaLite	<code>ST_IsValid(poly)</code>
Oracle	<code>SDO_GEOM.VALIDATE_GEOMETRY_WITH_CONTEXT(poly, 0.05) = 'TRUE'</code>

`overlaps`

Availability: [PostGIS](#), Oracle, MariaDB, MySQL, SpatiaLite, PGRaster (Bilateral)

Tests if the geometry field spatially overlaps the lookup geometry.

Backend	SQL Equivalent
PostGIS	<code>ST_Overlaps(poly, geom)</code>
Oracle	<code>SDO_OVERLAPS(poly, geom)</code>
MariaDB	<code>ST_Overlaps(poly, geom)</code>
MySQL	<code>ST_Overlaps(poly, geom)</code>
SpatiaLite	<code>Overlaps(poly, geom)</code>

relate

Availability: [PostGIS](#), MariaDB, Oracle, SpatiaLite, PGRaster (Conversion)

Tests if the geometry field is spatially related to the lookup geometry by the values given in the given pattern. This lookup requires a tuple parameter, (geom, pattern); the form of pattern will depend on the spatial backend:

MariaDB, PostGIS, and SpatiaLite

On these spatial backends the intersection pattern is a string comprising nine characters, which define intersections between the interior, boundary, and exterior of the geometry field and the lookup geometry. The intersection pattern matrix may only use the following characters: 1, 2, T, F, or *. This lookup type allows users to “fine tune” a specific geometric relationship consistent with the DE-9IM model.¹

Geometry example:

```
# A tuple lookup parameter is used to specify the geometry and
# the intersection pattern (the pattern here is for 'contains').
Zipcode.objects.filter(poly__relate=(geom, "T*T***FF*"))
```

PostGIS and MariaDB SQL equivalent:

```
SELECT ... WHERE ST_Relate(poly, geom, 'T*T***FF*')
```

SpatiaLite SQL equivalent:

```
SELECT ... WHERE Relate(poly, geom, 'T*T***FF*')
```

Raster example:

```
Zipcode.objects.filter(poly__relate=(rast, 1, "T*T***FF*"))
Zipcode.objects.filter(rast__2__relate=(rast, 1, "T*T***FF*"))
```

PostGIS SQL equivalent:

```
SELECT ... WHERE ST_Relate(poly, ST_Polygon(rast, 1), 'T*T***FF*')
SELECT ... WHERE ST_Relate(ST_Polygon(rast, 2), ST_Polygon(rast, 1), 'T*T***FF*')
```

¹ See [OpenGIS Simple Feature Specification For SQL](#), at Ch. 2.1.13.2, p. 2-13 (The Dimensionally Extended Nine-Intersection Model).

Oracle

Here the relation pattern is comprised of at least one of the nine relation strings: TOUCH, OVERLAPBDYDISJOINT, OVERLAPBDYINTERSECT, EQUAL, INSIDE, COVEREDBY, CONTAINS, COVERS, ON, and ANYINTERACT. Multiple strings may be combined with the logical Boolean operator OR, for example, 'inside+touch'.² The relation strings are case-insensitive.

Example:

```
Zipcode.objects.filter(poly__relate=(geom, "anyinteract"))
```

Oracle SQL equivalent:

```
SELECT ... WHERE SDO_RELATE(poly, geom, 'anyinteract')
```

touches

Availability: [PostGIS](#), Oracle, MariaDB, MySQL, SpatiaLite

Tests if the geometry field spatially touches the lookup geometry.

Example:

```
Zipcode.objects.filter(poly__touches=geom)
```

Backend	SQL Equivalent
PostGIS	ST_Touches(poly, geom)
MariaDB	ST_Touches(poly, geom)
MySQL	ST_Touches(poly, geom)
Oracle	SDO_TOUCH(poly, geom)
SpatiaLite	Touches(poly, geom)

within

Availability: [PostGIS](#), Oracle, MariaDB, MySQL, SpatiaLite, PGRaster (Bilateral)

Tests if the geometry field is spatially within the lookup geometry.

Example:

² See [SDO_RELATE](#) documentation, from the Oracle Spatial and Graph Developer's Guide.

```
Zipcode.objects.filter(poly__within=geom)
```

Backend	SQL Equivalent
PostGIS	ST_Within(poly, geom)
MariaDB	ST_Within(poly, geom)
MySQL	ST_Within(poly, geom)
Oracle	SDO_INSIDE(poly, geom)
Spatialite	Within(poly, geom)

left

Availability: [PostGIS](#), [PGRaster \(Conversion\)](#)

Tests if the geometry field's bounding box is strictly to the left of the lookup geometry's bounding box.

Example:

```
Zipcode.objects.filter(poly__left=geom)
```

PostGIS equivalent:

```
SELECT ... WHERE poly << geom
```

right

Availability: [PostGIS](#), [PGRaster \(Conversion\)](#)

Tests if the geometry field's bounding box is strictly to the right of the lookup geometry's bounding box.

Example:

```
Zipcode.objects.filter(poly__right=geom)
```

PostGIS equivalent:

```
SELECT ... WHERE poly >> geom
```

`overlaps_left`

Availability: [PostGIS](#), PGRaster (Bilateral)

Tests if the geometry field's bounding box overlaps or is to the left of the lookup geometry's bounding box.

Example:

```
Zipcode.objects.filter(poly__overlaps_left=geom)
```

PostGIS equivalent:

```
SELECT ... WHERE poly &< geom
```

`overlaps_right`

Availability: [PostGIS](#), PGRaster (Bilateral)

Tests if the geometry field's bounding box overlaps or is to the right of the lookup geometry's bounding box.

Example:

```
Zipcode.objects.filter(poly__overlaps_right=geom)
```

PostGIS equivalent:

```
SELECT ... WHERE poly &> geom
```

`overlaps_above`

Availability: [PostGIS](#), PGRaster (Conversion)

Tests if the geometry field's bounding box overlaps or is above the lookup geometry's bounding box.

Example:

```
Zipcode.objects.filter(poly__overlaps_above=geom)
```

PostGIS equivalent:

```
SELECT ... WHERE poly |&> geom
```

`overlaps_below`

Availability: [PostGIS](#), PGRaster (Conversion)

Tests if the geometry field's bounding box overlaps or is below the lookup geometry's bounding box.

Example:

```
Zipcode.objects.filter(poly__overlaps_below=geom)
```

PostGIS equivalent:

```
SELECT ... WHERE poly &<| geom
```

`strictly_above`

Availability: [PostGIS](#), PGRaster (Conversion)

Tests if the geometry field's bounding box is strictly above the lookup geometry's bounding box.

Example:

```
Zipcode.objects.filter(poly__strictly_above=geom)
```

PostGIS equivalent:

```
SELECT ... WHERE poly |>> geom
```

`strictly_below`

Availability: [PostGIS](#), PGRaster (Conversion)

Tests if the geometry field's bounding box is strictly below the lookup geometry's bounding box.

Example:

```
Zipcode.objects.filter(poly__strictly_below=geom)
```

PostGIS equivalent:

```
SELECT ... WHERE poly <<| geom
```

Distance Lookups

Availability: PostGIS, Oracle, MariaDB, MySQL, SpatiaLite, PGRaster (Native)

For an overview on performing distance queries, please refer to the [distance queries introduction](#).

Distance lookups take the following form:

```
<field>__<distance lookup>=(<geometry/raster>, <distance value>[, "spheroid"])
<field>__<distance lookup>=(<raster>, <band_index>, <distance value>[, "spheroid"])
<field>__<band_index>__<distance lookup>=(<raster>, <band_index>, <distance value>[, "spheroid"])
```

The value passed into a distance lookup is a tuple; the first two values are mandatory, and are the geometry to calculate distances to, and a distance value (either a number in units of the field, a *Distance* object, or a [query expression](#)). To pass a band index to the lookup, use a 3-tuple where the second entry is the band index.

On every distance lookup except *dwithin*, an optional element, 'spheroid', may be included to use the more accurate spheroid distance calculation functions on fields with a geodetic coordinate system.

On PostgreSQL, the 'spheroid' option uses `ST_DistanceSpheroid` instead of `ST_DistanceSphere`. The simpler `ST_Distance` function is used with projected coordinate systems. Rasters are converted to geometries for spheroid based lookups.

`distance_gt`

Returns models where the distance to the geometry field from the lookup geometry is greater than the given distance value.

Example:

```
Zipcode.objects.filter(poly__distance_gt=(geom, D(m=5)))
```

Backend	SQL Equivalent
PostGIS	<code>ST_Distance/ST_Distance_Sphere(poly, geom) > 5</code>
MariaDB	<code>ST_Distance(poly, geom) > 5</code>
MySQL	<code>ST_Distance(poly, geom) > 5</code>
Oracle	<code>SDO_GEOM.SDO_DISTANCE(poly, geom, 0.05) > 5</code>
SpatiaLite	<code>Distance(poly, geom) > 5</code>

`distance_gte`

Returns models where the distance to the geometry field from the lookup geometry is greater than or equal to the given distance value.

Example:

```
Zipcode.objects.filter(poly__distance_gte=(geom, D(m=5)))
```

Backend	SQL Equivalent
PostGIS	<code>ST_Distance/ST_Distance_Sphere(poly, geom) >= 5</code>
MariaDB	<code>ST_Distance(poly, geom) >= 5</code>
MySQL	<code>ST_Distance(poly, geom) >= 5</code>
Oracle	<code>SDO_GEOM.SDO_DISTANCE(poly, geom, 0.05) >= 5</code>
Spatialite	<code>Distance(poly, geom) >= 5</code>

`distance_lt`

Returns models where the distance to the geometry field from the lookup geometry is less than the given distance value.

Example:

```
Zipcode.objects.filter(poly__distance_lt=(geom, D(m=5)))
```

Backend	SQL Equivalent
PostGIS	<code>ST_Distance/ST_Distance_Sphere(poly, geom) < 5</code>
MariaDB	<code>ST_Distance(poly, geom) < 5</code>
MySQL	<code>ST_Distance(poly, geom) < 5</code>
Oracle	<code>SDO_GEOM.SDO_DISTANCE(poly, geom, 0.05) < 5</code>
Spatialite	<code>Distance(poly, geom) < 5</code>

`distance_lte`

Returns models where the distance to the geometry field from the lookup geometry is less than or equal to the given distance value.

Example:

```
Zipcode.objects.filter(poly__distance_lte=(geom, D(m=5)))
```

Backend	SQL Equivalent
PostGIS	<code>ST_Distance/ST_Distance_Sphere(poly, geom) <= 5</code>
MariaDB	<code>ST_Distance(poly, geom) <= 5</code>
MySQL	<code>ST_Distance(poly, geom) <= 5</code>
Oracle	<code>SDO_GEOM.SDO_DISTANCE(poly, geom, 0.05) <= 5</code>
Spatialite	<code>Distance(poly, geom) <= 5</code>

`dwithin`

Returns models where the distance to the geometry field from the lookup geometry are within the given distance from one another. Note that you can only provide *Distance* objects if the targeted geometries are in a projected system. For geographic geometries, you should use units of the geometry field (e.g. degrees for WGS84).

Example:

```
Zipcode.objects.filter(poly__dwithin=(geom, D(m=5)))
```

Backend	SQL Equivalent
PostGIS	<code>ST_DWithin(poly, geom, 5)</code>
Oracle	<code>SDO_WITHIN_DISTANCE(poly, geom, 5)</code>
Spatialite	<code>PtDistWithin(poly, geom, 5)</code>

Aggregate Functions

Django provides some GIS-specific aggregate functions. For details on how to use these aggregate functions, see [the topic guide on aggregation](#).

Keyword Argument	Description
<code>tolerance</code>	This keyword is for Oracle only. It is for the tolerance value used by the <code>SDOAGGRTYPE</code> procedure; the Oracle documentation has more details.

Example:

```
>>> from django.contrib.gis.db.models import Extent, Union
>>> WorldBorder.objects.aggregate(Extent("mpoly"), Union("mpoly"))
```

Collect

```
class Collect(geo_field)
```

Availability: [PostGIS](#), [SpatiaLite](#)

Returns a `GEOMETRYCOLLECTION` or a `MULTI` geometry object from the geometry column. This is analogous to a simplified version of the [Union](#) aggregate, except it can be several orders of magnitude faster than performing a union because it rolls up geometries into a collection or multi object, not caring about dissolving boundaries.

Extent

```
class Extent(geo_field)
```

Availability: [PostGIS](#), [Oracle](#), [SpatiaLite](#)

Returns the extent of all `geo_field` in the `QuerySet` as a four-tuple, comprising the lower left coordinate and the upper right coordinate.

Example:

```
>>> qs = City.objects.filter(name__in=("Houston", "Dallas")).aggregate(Extent("poly"))
>>> print(qs["poly__extent"])
(-96.8016128540039, 29.7633724212646, -95.3631439208984, 32.782058715820)
```

Extent3D

```
class Extent3D(geo_field)
```

Availability: [PostGIS](#)

Returns the 3D extent of all `geo_field` in the `QuerySet` as a six-tuple, comprising the lower left coordinate and upper right coordinate (each with x, y, and z coordinates).

Example:

```
>>> qs = City.objects.filter(name__in=("Houston", "Dallas")).aggregate(Extent3D("poly"))
>>> print(qs["poly__extent3d"])
(-96.8016128540039, 29.7633724212646, 0, -95.3631439208984, 32.782058715820, 0)
```

MakeLine

```
class MakeLine(geo_field)
```

Availability: [PostGIS](#), [Spatialite](#)

Returns a `LineString` constructed from the point field geometries in the `QuerySet`. Currently, ordering the queryset has no effect.

Example:

```
>>> qs = City.objects.filter(name__in=("Houston", "Dallas")).aggregate(MakeLine("poly"))
>>> print(qs["poly__makeline"])
LINESTRING (-95.3631510000000020 29.7633739999999989, -96.8016109999999941 32.7820570000000018)
```

Union

```
class Union(geo_field)
```

Availability: [PostGIS](#), [Oracle](#), [Spatialite](#)

This method returns a *GEOSGeometry* object comprising the union of every geometry in the queryset. Please note that use of `Union` is processor intensive and may take a significant amount of time on large querysets.

Note: If the computation time for using this method is too expensive, consider using *Collect* instead.

Example:

```
>>> u = Zipcode.objects.aggregate(Union(poly)) # This may take a long time.
>>> u = Zipcode.objects.filter(poly__within=bbox).aggregate(
...     Union(poly)
... ) # A more sensible approach.
```

Geographic Database Functions

The functions documented on this page allow users to access geographic database functions to be used in annotations, aggregations, or filters in Django.

Example:

```
>>> from django.contrib.gis.db.models.functions import Length
>>> Track.objects.annotate(length=Length("line")).filter(length__gt=100)
```

Not all backends support all functions, so refer to the documentation of each function to see if your database backend supports the function you want to use. If you call a geographic function on a backend that doesn't support it, you'll get a `NotImplementedError` exception.

Function's summary:

Measure- ment	Relationships	Opera- tions	Editors	Input for- mat	Output for- mat	Miscella- neous
<i>Area</i>	<i>Azimuth</i>	<i>Differen</i>	<i>ForcePolygonCW</i>		<i>AsGeoJSON</i>	<i>IsEmpty</i>
<i>Distance</i>	<i>BoundingCircle</i>	<i>Intersec</i>	<i>MakeValid</i>		<i>AsGML</i>	<i>IsValid</i>
<i>GeometryDi</i>	<i>Centroid</i>	<i>SymDiffe</i>	<i>Reverse</i>		<i>AsKML</i>	<i>MemSize</i>
<i>Length</i>	<i>Envelope</i>	<i>Union</i>	<i>Scale</i>		<i>AsSVG</i>	<i>NumGeometries</i>
<i>Perimeter</i>	<i>LineLocatePoint</i>		<i>SnapToGrid</i>	<i>FromWKB</i>	<i>AsWKB</i>	<i>NumPoints</i>
	<i>PointOnSurface</i>		<i>Transform</i>	<i>FromWKT</i>	<i>AsWKT</i>	
			<i>Translate</i>		<i>GeoHash</i>	

Area

```
class Area(expression, **extra)
```

Availability: MariaDB, MySQL, Oracle, PostGIS, SpatiaLite

Accepts a single geographic field or expression and returns the area of the field as an *Area* measure.

MySQL and SpatiaLite without LWGEOM/RTTOPO don't support area calculations on geographic SRSeS.

AsGeoJSON

```
class AsGeoJSON(expression, bbox=False, crs=False, precision=8, **extra)
```

Availability: MariaDB, MySQL, Oracle, PostGIS, SpatiaLite

Accepts a single geographic field or expression and returns a [GeoJSON](#) representation of the geometry. Note that the result is not a complete GeoJSON structure but only the `geometry` key content of a GeoJSON structure. See also [GeoJSON Serializer](#).

Example:

```
>>> City.objects.annotate(json=AsGeoJSON("point")).get(name="Chicago").json
{"type": "Point", "coordinates": [-87.65018, 41.85039]}
```

Keyword Argument	Description
<code>bbox</code>	Set this to <code>True</code> if you want the bounding box to be included in the returned GeoJSON. Ignored on Oracle.
<code>crs</code>	Set this to <code>True</code> if you want the coordinate reference system to be included in the returned GeoJSON. Ignored on MySQL and Oracle.
<code>precision</code>	It may be used to specify the number of significant digits for the coordinates in the GeoJSON representation –the default value is 8. Ignored on Oracle.

AsGML

```
class AsGML(expression, version=2, precision=8, **extra)
```

Availability: Oracle, PostGIS, SpatiaLite

Accepts a single geographic field or expression and returns a [Geographic Markup Language \(GML\)](#) representation of the geometry.

Example:

```
>>> qs = Zipcode.objects.annotate(gml=AsGML("poly"))
>>> print(qs[0].gml)
<gml:Polygon srsName="EPSG:4326"><gml:OuterBoundaryIs>-147.78711,70.245363 ...
-147.78711,70.245363</gml:OuterBoundaryIs></gml:Polygon>
```

Keyword Argument	Description
<code>precision</code>	Specifies the number of significant digits for the coordinates in the GML representation – the default value is 8. Ignored on Oracle.
<code>version</code>	Specifies the GML version to use: 2 (default) or 3.

AsKML

`class AsKML(expression, precision=8, **extra)`

Availability: [PostGIS](#), [SpatiaLite](#)

Accepts a single geographic field or expression and returns a [Keyhole Markup Language \(KML\)](#) representation of the geometry.

Example:

```
>>> qs = Zipcode.objects.annotate(kml=AsKML("poly"))
>>> print(qs[0].kml)
<Polygon><outerBoundaryIs><LinearRing><coordinates>-103.04135,36.217596,0 ...
-103.04135,36.217596,0</coordinates></LinearRing></outerBoundaryIs></Polygon>
```

Keyword Argument	Description
<code>precision</code>	This keyword may be used to specify the number of significant digits for the coordinates in the KML representation – the default value is 8.

AsSVG

`class AsSVG(expression, relative=False, precision=8, **extra)`

Availability: [PostGIS](#), [SpatiaLite](#)

Accepts a single geographic field or expression and returns a [Scalable Vector Graphics \(SVG\)](#) representation of the geometry.

Keyword Argument	Description
<code>relative</code>	If set to <code>True</code> , the path data will be implemented in terms of relative moves. Defaults to <code>False</code> , meaning that absolute moves are used instead.
<code>precision</code>	This keyword may be used to specify the number of significant digits for the coordinates in the SVG representation –the default value is 8.

AsWKB

```
class AsWKB(expression, **extra)
```

Availability: MariaDB, [MySQL](#), Oracle, [PostGIS](#), SpatiaLite

Accepts a single geographic field or expression and returns a [Well-known binary \(WKB\)](#) representation of the geometry.

Example:

```
>>> bytes(City.objects.annotate(wkb=AsWKB("point")).get(name="Chelyabinsk").wkb)
b'\x01\x01\x00\x00\x00]3\xf9f\x9b\x91K@\x00X\x1d9\xd2\xb9N@'
```

AsWKT

```
class AsWKT(expression, **extra)
```

Availability: MariaDB, [MySQL](#), Oracle, [PostGIS](#), SpatiaLite

Accepts a single geographic field or expression and returns a [Well-known text \(WKT\)](#) representation of the geometry.

Example:

```
>>> City.objects.annotate(wkt=AsWKT("point")).get(name="Chelyabinsk").wkt
'POINT (55.137555 61.451728)'
```

Azimuth

```
class Azimuth(point_a, point_b, **extra)
```

Availability: [PostGIS](#), [Spatialite](#) (LWGEOM/RTTOPO)

Returns the azimuth in radians of the segment defined by the given point geometries, or `None` if the two points are coincident. The azimuth is angle referenced from north and is positive clockwise: north = 0; east = $\pi/2$; south = π ; west = $3\pi/2$.

BoundingCircle

```
class BoundingCircle(expression, num_seg=48, **extra)
```

Availability: [PostGIS](#), [Oracle](#)

Accepts a single geographic field or expression and returns the smallest circle polygon that can fully contain the geometry.

The `num_seg` parameter is used only on [PostGIS](#).

Centroid

```
class Centroid(expression, **extra)
```

Availability: [MariaDB](#), [MySQL](#), [PostGIS](#), [Oracle](#), [Spatialite](#)

Accepts a single geographic field or expression and returns the `centroid` value of the geometry.

Difference

```
class Difference(expr1, expr2, **extra)
```

Availability: [MariaDB](#), [MySQL](#), [PostGIS](#), [Oracle](#), [Spatialite](#)

Accepts two geographic fields or expressions and returns the geometric difference, that is the part of geometry A that does not intersect with geometry B.

Distance

```
class Distance(expr1, expr2, spheroid=None, **extra)
```

Availability: MariaDB, MySQL, PostGIS, Oracle, SpatiaLite

Accepts two geographic fields or expressions and returns the distance between them, as a *Distance* object. On MySQL, a raw float value is returned when the coordinates are geodetic.

On backends that support distance calculation on geodetic coordinates, the proper backend function is automatically chosen depending on the SRID value of the geometries (e.g. *ST_DistanceSphere* on PostGIS).

When distances are calculated with geodetic (angular) coordinates, as is the case with the default WGS84 (4326) SRID, you can set the *spheroid* keyword argument to decide if the calculation should be based on a simple sphere (less accurate, less resource-intensive) or on a spheroid (more accurate, more resource-intensive).

In the following example, the distance from the city of Hobart to every other *PointField* in the *AustraliaCity* queryset is calculated:

```
>>> from django.contrib.gis.db.models.functions import Distance
>>> pnt = AustraliaCity.objects.get(name="Hobart").point
>>> for city in AustraliaCity.objects.annotate(distance=Distance("point", pnt)):
...     print(city.name, city.distance)
...
Wollongong 990071.220408 m
Shellharbour 972804.613941 m
Thirroul 1002334.36351 m
...
```

Note: Because the *distance* attribute is a *Distance* object, you can easily express the value in the units of your choice. For example, *city.distance.mi* is the distance value in miles and *city.distance.km* is the distance value in kilometers. See [Measurement Objects](#) for usage details and the list of [Supported units](#).

Envelope

```
class Envelope(expression, **extra)
```

Availability: MariaDB, MySQL, Oracle, PostGIS, SpatiaLite

Accepts a single geographic field or expression and returns the geometry representing the bounding box of the geometry.

ForcePolygonCW

```
class ForcePolygonCW(expression, **extra)
```

Availability: [PostGIS](#), [Spatialite](#)

Accepts a single geographic field or expression and returns a modified version of the polygon/multipolygon in which all exterior rings are oriented clockwise and all interior rings are oriented counterclockwise. Non-polygonal geometries are returned unchanged.

FromWKB

```
class FromWKB(expression, **extra)
```

Availability: [MariaDB](#), [MySQL](#), [Oracle](#), [PostGIS](#), [Spatialite](#)

Creates geometry from [Well-known binary \(WKB\)](#) representation.

FromWKT

```
class FromWKT(expression, **extra)
```

Availability: [MariaDB](#), [MySQL](#), [Oracle](#), [PostGIS](#), [Spatialite](#)

Creates geometry from [Well-known text \(WKT\)](#) representation.

GeoHash

```
class GeoHash(expression, precision=None, **extra)
```

Availability: [MySQL](#), [PostGIS](#), [Spatialite](#) (LWGEOM/RTTOPO)

Accepts a single geographic field or expression and returns a [GeoHash](#) representation of the geometry.

The `precision` keyword argument controls the number of characters in the result.

GeometryDistance

```
class GeometryDistance(expr1, expr2, **extra)
```

Availability: [PostGIS](#)

Accepts two geographic fields or expressions and returns the distance between them. When used in an `order_by()` clause, it provides index-assisted nearest-neighbor result sets.

Intersection

```
class Intersection(expr1, expr2, **extra)
```

Availability: MariaDB, MySQL, PostGIS, Oracle, SpatiaLite

Accepts two geographic fields or expressions and returns the geometric intersection between them.

IsEmpty

```
class IsEmpty(expr)
```

Availability: PostGIS

Accepts a geographic field or expression and tests if the value is an empty geometry. Returns `True` if its value is empty and `False` otherwise.

IsValid

```
class IsValid(expr)
```

Availability: MySQL, PostGIS, Oracle, SpatiaLite

Accepts a geographic field or expression and tests if the value is well formed. Returns `True` if its value is a valid geometry and `False` otherwise.

Length

```
class Length(expression, spheroid=True, **extra)
```

Availability: MariaDB, MySQL, Oracle, PostGIS, SpatiaLite

Accepts a single geographic linestring or multilinestring field or expression and returns its length as a *Distance* measure.

On PostGIS and SpatiaLite, when the coordinates are geodetic (angular), you can specify if the calculation should be based on a simple sphere (less accurate, less resource-intensive) or on a spheroid (more accurate, more resource-intensive) with the `spheroid` keyword argument.

MySQL doesn't support length calculations on geographic SRSEs.

LineLocatePoint

```
class LineLocatePoint(linestring, point, **extra)
```

Availability: [PostGIS](#), [SpatiaLite](#)

Returns a float between 0 and 1 representing the location of the closest point on `linestring` to the given `point`, as a fraction of the 2D line length.

MakeValid

```
class MakeValid(expr)
```

Availability: [PostGIS](#), [SpatiaLite](#) (LWGEOM/RTTOPO)

Accepts a geographic field or expression and attempts to convert the value into a valid geometry without losing any of the input vertices. Geometries that are already valid are returned without changes. Simple polygons might become a multipolygon and the result might be of lower dimension than the input.

MemSize

```
class MemSize(expression, **extra)
```

Availability: [PostGIS](#)

Accepts a single geographic field or expression and returns the memory size (number of bytes) that the geometry field takes.

NumGeometries

```
class NumGeometries(expression, **extra)
```

Availability: [MariaDB](#), [MySQL](#), [PostGIS](#), [Oracle](#), [SpatiaLite](#)

Accepts a single geographic field or expression and returns the number of geometries if the geometry field is a collection (e.g., a `GEOMETRYCOLLECTION` or `MULTI*` field). Returns 1 for single geometries.

On [MySQL](#), returns `None` for single geometries.

NumPoints

```
class NumPoints(expression, **extra)
```

Availability: MariaDB, MySQL, PostGIS, Oracle, SpatiaLite

Accepts a single geographic field or expression and returns the number of points in a geometry.

On MySQL, returns `None` for any non-LINESTRING geometry.

Perimeter

```
class Perimeter(expression, **extra)
```

Availability: PostGIS, Oracle, SpatiaLite

Accepts a single geographic field or expression and returns the perimeter of the geometry field as a *Distance* object.

PointOnSurface

```
class PointOnSurface(expression, **extra)
```

Availability: PostGIS, MariaDB, Oracle, SpatiaLite

Accepts a single geographic field or expression and returns a `Point` geometry guaranteed to lie on the surface of the field; otherwise returns `None`.

Reverse

```
class Reverse(expression, **extra)
```

Availability: PostGIS, Oracle, SpatiaLite

Accepts a single geographic field or expression and returns a geometry with reversed coordinates.

Scale

```
class Scale(expression, x, y, z=0.0, **extra)
```

Availability: PostGIS, SpatiaLite

Accepts a single geographic field or expression and returns a geometry with scaled coordinates by multiplying them with the `x`, `y`, and optionally `z` parameters.

SnapToGrid

```
class SnapToGrid(expression, *args, **extra)
```

Availability: [PostGIS](#), [Spatialite](#)

Accepts a single geographic field or expression and returns a geometry with all points snapped to the given grid. How the geometry is snapped to the grid depends on how many numeric (either float, integer, or long) arguments are given.

Number of Arguments	Description
1	A single size to snap both the X and Y grids to.
2	X and Y sizes to snap the grid to.
4	X, Y sizes and the corresponding X, Y origins.

SymDifference

```
class SymDifference(expr1, expr2, **extra)
```

Availability: [MariaDB](#), [MySQL](#), [PostGIS](#), [Oracle](#), [Spatialite](#)

Accepts two geographic fields or expressions and returns the geometric symmetric difference (union without the intersection) between the given parameters.

Transform

```
class Transform(expression, srid, **extra)
```

Availability: [PostGIS](#), [Oracle](#), [Spatialite](#)

Accepts a geographic field or expression and a SRID integer code, and returns the transformed geometry to the spatial reference system specified by the `srid` parameter.

Note: What spatial reference system an integer SRID corresponds to may depend on the spatial database used. In other words, the SRID numbers used for Oracle are not necessarily the same as those used by PostGIS.

Translate

```
class Translate(expression, x, y, z=0.0, **extra)
```

Availability: [PostGIS](#), [Spatialite](#)

Accepts a single geographic field or expression and returns a geometry with its coordinates offset by the `x`, `y`, and optionally `z` numeric parameters.

Union

```
class Union(expr1, expr2, **extra)
```

Availability: [MariaDB](#), [MySQL](#), [PostGIS](#), [Oracle](#), [Spatialite](#)

Accepts two geographic fields or expressions and returns the union of both geometries.

Measurement Objects

The `django.contrib.gis.measure` module contains objects that allow for convenient representation of distance and area units of measure.¹ Specifically, it implements two objects, *Distance* and *Area*—both of which may be accessed via the *D* and *A* convenience aliases, respectively.

Example

Distance objects may be instantiated using a keyword argument indicating the context of the units. In the example below, two different distance objects are instantiated in units of kilometers (km) and miles (mi):

```
>>> from django.contrib.gis.measure import D, Distance
>>> d1 = Distance(km=5)
>>> print(d1)
5.0 km
>>> d2 = D(mi=5) # `D` is an alias for `Distance`
>>> print(d2)
5.0 mi
```

For conversions, access the preferred unit attribute to get a converted distance quantity:

```
>>> print(d1.mi) # Converting 5 kilometers to miles
3.10685596119
>>> print(d2.km) # Converting 5 miles to kilometers
8.04672
```

¹ [Robert Coup](#) is the initial author of the measure objects, and was inspired by Brian Beck's work in [geopy](#) and Geoff Biggs' PhD work on dimensioned units for robotics.

Moreover, arithmetic operations may be performed between the distance objects:

```
>>> print(d1 + d2)  # Adding 5 miles to 5 kilometers
13.04672 km
>>> print(d2 - d1)  # Subtracting 5 kilometers from 5 miles
1.89314403881 mi
```

Two *Distance* objects multiplied together will yield an *Area* object, which uses squared units of measure:

```
>>> a = d1 * d2  # Returns an Area object.
>>> print(a)
40.2336 sq_km
```

To determine what the attribute abbreviation of a unit is, the `unit_attname` class method may be used:

```
>>> print(Distance.unit_attname("US Survey Foot"))
survey_ft
>>> print(Distance.unit_attname("centimeter"))
cm
```

Supported units

Unit Attribute	Full name or alias(es)
km	Kilometre, Kilometer
mi	Mile
m	Meter, Metre
yd	Yard
ft	Foot, Foot (International)
survey_ft	U.S. Foot, US survey foot
inch	Inches
cm	Centimeter
mm	Millimetre, Millimeter
um	Micrometer, Micrometre
british_ft	British foot (Sears 1922)
british_yd	British yard (Sears 1922)
british_chain_sears	British chain (Sears 1922)
indian_yd	Indian yard, Yard (Indian)
sears_yd	Yard (Sears)
clarke_ft	Clarke' s Foot
chain	Chain
chain_benoit	Chain (Benoit)

continues on next page

Table 3 – continued from previous page

Unit Attribute	Full name or alias(es)
chain_sears	Chain (Sears)
british_chain_benoit	British chain (Benoit 1895 B)
british_chain_sears_truncated	British chain (Sears 1922 truncated)
gold_coast_ft	Gold Coast foot
link	Link
link_benoit	Link (Benoit)
link_sears	Link (Sears)
clarke_link	Clarke' s link
fathom	Fathom
rod	Rod
furlong	Furlong, Furrow Long
nm	Nautical Mile
nm_uk	Nautical Mile (UK)
german_m	German legal metre

Note: *Area* attributes are the same as *Distance* attributes, except they are prefixed with `sq_` (area units are square in nature). For example, `Area(sq_m=2)` creates an *Area* object representing two square meters.

Measurement API

Distance

```
class Distance(**kwargs)
```

To initialize a distance object, pass in a keyword corresponding to the desired *unit attribute name* set with desired value. For example, the following creates a distance object representing 5 miles:

```
>>> dist = Distance(mi=5)
```

```
__getattr__(unit_att)
```

Returns the distance value in units corresponding to the given unit attribute. For example:

```
>>> print(dist.km)
8.04672
```

```
classmethod unit_attname(unit_name)
```

Returns the distance unit attribute name for the given full unit name. For example:

```
>>> Distance.unit_attname("Mile")
'mi'
```

class D

Alias for *Distance* class.

Area

class Area(**kwargs)

To initialize an area object, pass in a keyword corresponding to the desired *unit attribute name* set with desired value. For example, the following creates an area object representing 5 square miles:

```
>>> a = Area(sq_mi=5)
```

__getattr__(unit_att)

Returns the area value in units corresponding to the given unit attribute. For example:

```
>>> print(a.sq_km)
12.949940551680001
```

classmethod unit_attname(unit_name)

Returns the area unit attribute name for the given full unit name. For example:

```
>>> Area.unit_attname("Kilometer")
'sq_km'
```

class A

Alias for *Area* class.

GEOS API

Background

What is GEOS?

GEOS stands for Geometry Engine - Open Source, and is a C++ library, ported from the *Java Topology Suite*. GEOS implements the OpenGIS *Simple Features for SQL* spatial predicate functions and spatial operators. GEOS, now an OSGeo project, was initially developed and maintained by *Refractions Research* of Victoria, Canada.

Features

GeoDjango implements a high-level Python wrapper for the GEOS library, its features include:

- A BSD-licensed interface to the GEOS geometry routines, implemented purely in Python using `ctypes`.
- Loosely-coupled to GeoDjango. For example, *GEOSGeometry* objects may be used outside of a Django project/application. In other words, no need to have `DJANGO_SETTINGS_MODULE` set or use a database, etc.
- Mutability: *GEOSGeometry* objects may be modified.
- Cross-platform and tested; compatible with Windows, Linux, Solaris, and macOS platforms.

Tutorial

This section contains a brief introduction and tutorial to using *GEOSGeometry* objects.

Creating a Geometry

GEOSGeometry objects may be created in a few ways. The first is to simply instantiate the object on some spatial input –the following are examples of creating the same geometry from WKT, HEX, WKB, and GeoJSON:

```
>>> from django.contrib.gis.geos import GEOSGeometry
>>> pnt = GEOSGeometry("POINT(5 23)") # WKT
>>> pnt = GEOSGeometry("010100000000000000000000014400000000000003740") # HEX
>>> pnt = GEOSGeometry(
...     memoryview(
...         b"\x01\x01\x00\x00\x00\x00\x00\x00\x00\x00\x00\x00\x14@\x00\x00\x00\x00\x00\x007@"
...     )
... ) # WKB
>>> pnt = GEOSGeometry(
...     '{"type": "Point", "coordinates": [ 5.000000, 23.000000 ] }'
... ) # GeoJSON
```

Another option is to use the constructor for the specific geometry type that you wish to create. For example, a *Point* object may be created by passing in the X and Y coordinates into its constructor:

```
>>> from django.contrib.gis.geos import Point
>>> pnt = Point(5, 23)
```

All these constructors take the keyword argument `srid`. For example:

```
>>> from django.contrib.gis.geos import GEOSGeometry, LineString, Point
>>> print(GEOSGeometry("POINT (0 0)", srid=4326))
SRID=4326;POINT (0 0)
>>> print(LineString((0, 0), (1, 1), srid=4326))
SRID=4326;LINESTRING (0 0, 1 1)
>>> print(Point(0, 0, srid=32140))
SRID=32140;POINT (0 0)
```

Finally, there is the *fromfile()* factory method which returns a *GEOSGeometry* object from a file:

```
>>> from django.contrib.gis.geos import fromfile
>>> pnt = fromfile("/path/to/pnt.wkt")
>>> pnt = fromfile(open("/path/to/pnt.wkt"))
```

My logs are filled with GEOS-related errors

You find many `TypeError` or `AttributeError` exceptions filling your web server's log files. This generally means that you are creating GEOS objects at the top level of some of your Python modules. Then, due to a race condition in the garbage collector, your module is garbage collected before the GEOS object. To prevent this, create *GEOSGeometry* objects inside the local scope of your functions/methods.

Geometries are Pythonic

GEOSGeometry objects are 'Pythonic', in other words components may be accessed, modified, and iterated over using standard Python conventions. For example, you can iterate over the coordinates in a *Point*:

```
>>> pnt = Point(5, 23)
>>> [coord for coord in pnt]
[5.0, 23.0]
```

With any geometry object, the *GEOSGeometry.coords* property may be used to get the geometry coordinates as a Python tuple:

```
>>> pnt.coords
(5.0, 23.0)
```

You can get/set geometry components using standard Python indexing techniques. However, what is returned depends on the geometry type of the object. For example, indexing on a *LineString* returns a coordinate tuple:

```
>>> from django.contrib.gis.geos import LineString
>>> line = LineString((0, 0), (0, 50), (50, 50), (50, 0), (0, 0))
```

(continues on next page)

(continued from previous page)

```
>>> line[0]
(0.0, 0.0)
>>> line[-2]
(50.0, 0.0)
```

Whereas indexing on a *Polygon* will return the ring (a *LinearRing* object) corresponding to the index:

```
>>> from django.contrib.gis.geos import Polygon
>>> poly = Polygon(((0.0, 0.0), (0.0, 50.0), (50.0, 50.0), (50.0, 0.0), (0.0, 0.0)))
>>> poly[0]
<LinearRing object at 0x1044395b0>
>>> poly[0][-2] # second-to-last coordinate of external ring
(50.0, 0.0)
```

In addition, coordinates/components of the geometry may added or modified, just like a Python list:

```
>>> line[0] = (1.0, 1.0)
>>> line.pop()
(0.0, 0.0)
>>> line.append((1.0, 1.0))
>>> line.coords
((1.0, 1.0), (0.0, 50.0), (50.0, 50.0), (50.0, 0.0), (1.0, 1.0))
```

Geometries support set-like operators:

```
>>> from django.contrib.gis.geos import LineString
>>> ls1 = LineString((0, 0), (2, 2))
>>> ls2 = LineString((1, 1), (3, 3))
>>> print(ls1 | ls2) # equivalent to `ls1.union(ls2)`
MULTILINESTRING ((0 0, 1 1), (1 1, 2 2), (2 2, 3 3))
>>> print(ls1 & ls2) # equivalent to `ls1.intersection(ls2)`
LINESTRING (1 1, 2 2)
>>> print(ls1 - ls2) # equivalent to `ls1.difference(ls2)`
LINESTRING(0 0, 1 1)
>>> print(ls1 ^ ls2) # equivalent to `ls1.sym_difference(ls2)`
MULTILINESTRING ((0 0, 1 1), (2 2, 3 3))
```

Equality operator doesn't check spatial equality

The *GEOSGeometry* equality operator uses *equals_exact()*, not *equals()*, i.e. it requires the compared geometries to have the same coordinates in the same positions with the same SRIDs:

```
>>> from django.contrib.gis.geos import LineString
>>> ls1 = LineString((0, 0), (1, 1))
```

(continues on next page)

(continued from previous page)

```
>>> ls2 = LineString((1, 1), (0, 0))
>>> ls3 = LineString((1, 1), (0, 0), srid=4326)
>>> ls1.equals(ls2)
True
>>> ls1 == ls2
False
>>> ls3 == ls2  # different SRIDs
False
```

Geometry Objects

GEOSGeometry

```
class GEOSGeometry(geo_input, srid=None)
```

Parameters

- **geo_input** –Geometry input value (string or `memoryview`)
- **srid** (`int`) –spatial reference identifier

This is the base class for all GEOS geometry objects. It initializes on the given `geo_input` argument, and then assumes the proper geometry subclass (e.g., `GEOSGeometry('POINT(1 1)')` will create a `Point` object).

The `srid` parameter, if given, is set as the SRID of the created geometry if `geo_input` doesn't have an SRID. If different SRIDs are provided through the `geo_input` and `srid` parameters, `ValueError` is raised:

```
>>> from django.contrib.gis.geos import GEOSGeometry
>>> GEOSGeometry("POINT EMPTY", srid=4326).ewkt
'SRID=4326;POINT EMPTY'
>>> GEOSGeometry("SRID=4326;POINT EMPTY", srid=4326).ewkt
'SRID=4326;POINT EMPTY'
>>> GEOSGeometry("SRID=1;POINT EMPTY", srid=4326)
Traceback (most recent call last):
...
ValueError: Input geometry already has SRID: 1.
```

The following input formats, along with their corresponding Python types, are accepted:

Format	Input Type
WKT / EWKT	str
HEX / HEXEWKB	str
WKB / EWKB	memoryview
GeoJSON	str

For the GeoJSON format, the SRID is set based on the `crs` member. If `crs` isn't provided, the SRID defaults to 4326.

classmethod `GEOSGeometry.from_gml(gml_string)`

Constructs a *GEOSGeometry* from the given GML string.

Properties

`GEOSGeometry.coords`

Returns the coordinates of the geometry as a tuple.

`GEOSGeometry.dims`

Returns the dimension of the geometry:

- 0 for *Points* and *MultiPoints*
- 1 for *LineStrings* and *MultiLineStrings*
- 2 for *Polygons* and *MultiPolygons*
- -1 for empty *GeometryCollections*
- the maximum dimension of its elements for non-empty *GeometryCollections*

`GEOSGeometry.empty`

Returns whether or not the set of points in the geometry is empty.

`GEOSGeometry.geom_type`

Returns a string corresponding to the type of geometry. For example:

```
>>> pnt = GEOSGeometry("POINT(5 23)")
>>> pnt.geom_type
'Point'
```

`GEOSGeometry.geom_typeid`

Returns the GEOS geometry type identification number. The following table shows the value for each geometry type:

Geometry	ID
<i>Point</i>	0
<i>LineString</i>	1
<i>LinearRing</i>	2
<i>Polygon</i>	3
<i>MultiPoint</i>	4
<i>MultiLineString</i>	5
<i>MultiPolygon</i>	6
<i>GeometryCollection</i>	7

GEOSGeometry.num_coords

Returns the number of coordinates in the geometry.

GEOSGeometry.num_geom

Returns the number of geometries in this geometry. In other words, will return 1 on anything but geometry collections.

GEOSGeometry.hasz

Returns a boolean indicating whether the geometry is three-dimensional.

GEOSGeometry.ring

Returns a boolean indicating whether the geometry is a *LinearRing*.

GEOSGeometry.simple

Returns a boolean indicating whether the geometry is ‘simple’. A geometry is simple if and only if it does not intersect itself (except at boundary points). For example, a *LineString* object is not simple if it intersects itself. Thus, *LinearRing* and *Polygon* objects are always simple because they do cannot intersect themselves, by definition.

GEOSGeometry.valid

Returns a boolean indicating whether the geometry is valid.

GEOSGeometry.valid_reason

Returns a string describing the reason why a geometry is invalid.

GEOSGeometry.srid

Property that may be used to retrieve or set the SRID associated with the geometry. For example:

```
>>> pnt = Point(5, 23)
>>> print(pnt.srid)
None
>>> pnt.srid = 4326
>>> pnt.srid
4326
```

Output Properties

The properties in this section export the *GEOSGeometry* object into a different. This output may be in the form of a string, buffer, or even another object.

GEOSGeometry.ewkt

Returns the “extended” Well-Known Text of the geometry. This representation is specific to PostGIS and is a superset of the OGC WKT standard.¹ Essentially the SRID is prepended to the WKT representation, for example `SRID=4326;POINT(5 23)`.

Note: The output from this property does not include the 3dm, 3dz, and 4d information that PostGIS supports in its EWKT representations.

GEOSGeometry.hex

Returns the WKB of this Geometry in hexadecimal form. Please note that the SRID value is not included in this representation because it is not a part of the OGC specification (use the *GEOSGeometry.hexewkb* property instead).

GEOSGeometry.hexewkb

Returns the EWKB of this Geometry in hexadecimal form. This is an extension of the WKB specification that includes the SRID value that are a part of this geometry.

GEOSGeometry.json

Returns the GeoJSON representation of the geometry. Note that the result is not a complete GeoJSON structure but only the `geometry` key content of a GeoJSON structure. See also [GeoJSON Serializer](#).

GEOSGeometry.geojson

Alias for *GEOSGeometry.json*.

GEOSGeometry.kml

Returns a [KML](#) (Keyhole Markup Language) representation of the geometry. This should only be used for geometries with an SRID of 4326 (WGS84), but this restriction is not enforced.

GEOSGeometry.ogr

Returns an *OGREGeometry* object corresponding to the GEOS geometry.

GEOSGeometry.wkb

Returns the WKB (Well-Known Binary) representation of this Geometry as a Python buffer. SRID value is not included, use the *GEOSGeometry.ewkb* property instead.

GEOSGeometry.ewkb

Return the EWKB representation of this Geometry as a Python buffer. This is an extension of the WKB specification that includes any SRID value that are a part of this geometry.

¹ See [PostGIS EWKB, EWKT and Canonical Forms](#), PostGIS documentation at Ch. 4.1.2.

`GEOSGeometry.wkt`

Returns the Well-Known Text of the geometry (an OGC standard).

Spatial Predicate Methods

All of the following spatial predicate methods take another *GEOSGeometry* instance (*other*) as a parameter, and return a boolean.

`GEOSGeometry.contains(other)`

Returns True if *other.within(this)* returns True.

`GEOSGeometry.covers(other)`

Returns True if this geometry covers the specified geometry.

The `covers` predicate has the following equivalent definitions:

- Every point of the other geometry is a point of this geometry.
- The DE-9IM Intersection Matrix for the two geometries is `T*****FF*`, `*T*****FF*`, `***T**FF*`, or `****T*FF*`.

If either geometry is empty, returns False.

This predicate is similar to *GEOSGeometry.contains()*, but is more inclusive (i.e. returns True for more cases). In particular, unlike *contains()* it does not distinguish between points in the boundary and in the interior of geometries. For most situations, `covers()` should be preferred to *contains()*. As an added benefit, `covers()` is more amenable to optimization and hence should outperform *contains()*.

`GEOSGeometry.crosses(other)`

Returns True if the DE-9IM intersection matrix for the two Geometries is `T*T*****` (for a point and a curve, a point and an area or a line and an area) `0*****` (for two curves).

`GEOSGeometry.disjoint(other)`

Returns True if the DE-9IM intersection matrix for the two geometries is `FF*FF****`.

`GEOSGeometry.equals(other)`

Returns True if the DE-9IM intersection matrix for the two geometries is `T*F**FFF*`.

`GEOSGeometry.equals_exact(other, tolerance=0)`

Returns true if the two geometries are exactly equal, up to a specified tolerance. The `tolerance` value should be a floating point number representing the error tolerance in the comparison, e.g., `poly1.equals_exact(poly2, 0.001)` will compare equality to within one thousandth of a unit.

`GEOSGeometry.intersects(other)`

Returns True if *GEOSGeometry.disjoint()* is False.

`GEOSGeometry.overlaps(other)`

Returns true if the DE-9IM intersection matrix for the two geometries is `T*T***T**` (for two points or two surfaces) `1*T***T**` (for two curves).

`GEOSGeometry.relate_pattern(other, pattern)`

Returns True if the elements in the DE-9IM intersection matrix for this geometry and the other matches the given `pattern` –a string of nine characters from the alphabet: `{T, F, *, 0}`.

`GEOSGeometry.touches(other)`

Returns True if the DE-9IM intersection matrix for the two geometries is `FT*****`, `F**T*****` or `F***T*****`.

`GEOSGeometry.within(other)`

Returns True if the DE-9IM intersection matrix for the two geometries is `T*F**F***`.

Topological Methods

`GEOSGeometry.buffer(width, quadsegs=8)`

Returns a *GEOSGeometry* that represents all points whose distance from this geometry is less than or equal to the given `width`. The optional `quadsegs` keyword sets the number of segments used to approximate a quarter circle (defaults is 8).

`GEOSGeometry.buffer_with_style(width, quadsegs=8, end_cap_style=1, join_style=1, mitre_limit=5.0)`

Same as *buffer()*, but allows customizing the style of the buffer.

- `end_cap_style` can be round (1), flat (2), or square (3).
- `join_style` can be round (1), mitre (2), or bevel (3).
- Mitre ratio limit (`mitre_limit`) only affects mitered join style.

`GEOSGeometry.difference(other)`

Returns a *GEOSGeometry* representing the points making up this geometry that do not make up other.

`GEOSGeometry.interpolate(distance)`

`GEOSGeometry.interpolate_normalized(distance)`

Given a distance (float), returns the point (or closest point) within the geometry (*LineString* or *MultiLineString*) at that distance. The normalized version takes the distance as a float between 0 (origin) and 1 (endpoint).

Reverse of *GEOSGeometry.project()*.

`GEOSGeometry.intersection(other)`

Returns a *GEOSGeometry* representing the points shared by this geometry and other.

`GEOSGeometry.project(point)`

`GEOSGeometry.project_normalized(point)`

Returns the distance (float) from the origin of the geometry (*LineString* or *MultiLineString*) to the point projected on the geometry (that is to a point of the line the closest to the given point). The normalized version returns the distance as a float between 0 (origin) and 1 (endpoint).

Reverse of *GEOSGeometry.interpolate()*.

`GEOSGeometry.relate(other)`

Returns the DE-9IM intersection matrix (a string) representing the topological relationship between this geometry and the other.

`GEOSGeometry.simplify(tolerance=0.0, preserve_topology=False)`

Returns a new *GEOSGeometry*, simplified to the specified tolerance using the Douglas-Peucker algorithm. A higher tolerance value implies fewer points in the output. If no tolerance is provided, it defaults to 0.

By default, this function does not preserve topology. For example, *Polygon* objects can be split, be collapsed into lines, or disappear. *Polygon* holes can be created or disappear, and lines may cross. By specifying `preserve_topology=True`, the result will have the same dimension and number of components as the input; this is significantly slower, however.

`GEOSGeometry.sym_difference(other)`

Returns a *GEOSGeometry* combining the points in this geometry not in other, and the points in other not in this geometry.

`GEOSGeometry.union(other)`

Returns a *GEOSGeometry* representing all the points in this geometry and the other.

Topological Properties

`GEOSGeometry.boundary`

Returns the boundary as a newly allocated Geometry object.

`GEOSGeometry.centroid`

Returns a *Point* object representing the geometric center of the geometry. The point is not guaranteed to be on the interior of the geometry.

`GEOSGeometry.convex_hull`

Returns the smallest *Polygon* that contains all the points in the geometry.

`GEOSGeometry.envelope`

Returns a *Polygon* that represents the bounding envelope of this geometry. Note that it can also return a *Point* if the input geometry is a point.

`GEOSGeometry.point_on_surface`

Computes and returns a *Point* guaranteed to be on the interior of this geometry.

GEOSGeometry.unary_union

Computes the union of all the elements of this geometry.

The result obeys the following contract:

- Unioning a set of *LineStrings* has the effect of fully noding and dissolving the linework.
- Unioning a set of *Polygons* will always return a *Polygon* or *MultiPolygon* geometry (unlike *GEOSGeometry.union()*, which may return geometries of lower dimension if a topology collapse occurs).

Other Properties & Methods**GEOSGeometry.area**

This property returns the area of the Geometry.

GEOSGeometry.extent

This property returns the extent of this geometry as a 4-tuple, consisting of (xmin, ymin, xmax, ymax).

GEOSGeometry.clone()

This method returns a *GEOSGeometry* that is a clone of the original.

GEOSGeometry.distance(geom)

Returns the distance between the closest points on this geometry and the given geom (another *GEOSGeometry* object).

Note: GEOS distance calculations are linear –in other words, GEOS does not perform a spherical calculation even if the SRID specifies a geographic coordinate system.

GEOSGeometry.length

Returns the length of this geometry (e.g., 0 for a *Point*, the length of a *LineString*, or the circumference of a *Polygon*).

GEOSGeometry.prepared

Returns a GEOS PreparedGeometry for the contents of this geometry. PreparedGeometry objects are optimized for the contains, intersects, covers, crosses, disjoint, overlaps, touches and within operations. Refer to the [Prepared Geometries](#) documentation for more information.

GEOSGeometry.srs

Returns a *SpatialReference* object corresponding to the SRID of the geometry or None.

GEOSGeometry.transform(ct, clone=False)

Transforms the geometry according to the given coordinate transformation parameter (ct), which may

be an integer SRID, spatial reference WKT string, a PROJ string, a *SpatialReference* object, or a *CoordTransform* object. By default, the geometry is transformed in-place and nothing is returned. However if the `clone` keyword is set, then the geometry is not modified and a transformed clone of the geometry is returned instead.

Note: Raises *GEOSException* if GDAL is not available or if the geometry's SRID is `None` or less than 0. It doesn't impose any constraints on the geometry's SRID if called with a *CoordTransform* object.

`GEOSGeometry.make_valid()`

Returns a valid *GEOSGeometry* equivalent, trying not to lose any of the input vertices. If the geometry is already valid, it is returned untouched. This is similar to the *MakeValid* database function. Requires GEOS 3.8.

`GEOSGeometry.normalize(clone=False)`

Converts this geometry to canonical form. If the `clone` keyword is set, then the geometry is not modified and a normalized clone of the geometry is returned instead:

```
>>> g = MultiPoint(Point(0, 0), Point(2, 2), Point(1, 1))
>>> print(g)
MULTIPOINT (0 0, 2 2, 1 1)
>>> g.normalize()
>>> print(g)
MULTIPOINT (2 2, 1 1, 0 0)
```

The `clone` argument was added.

Point

class `Point(x=None, y=None, z=None, srid=None)`

`Point` objects are instantiated using arguments that represent the component coordinates of the point or with a single sequence coordinates. For example, the following are equivalent:

```
>>> pnt = Point(5, 23)
>>> pnt = Point([5, 23])
```

Empty `Point` objects may be instantiated by passing no arguments or an empty sequence. The following are equivalent:

```
>>> pnt = Point()
>>> pnt = Point([])
```

LineString

class `LineString(*args, **kwargs)`

`LineString` objects are instantiated using arguments that are either a sequence of coordinates or *Point* objects. For example, the following are equivalent:

```
>>> ls = LineString((0, 0), (1, 1))
>>> ls = LineString(Point(0, 0), Point(1, 1))
```

In addition, `LineString` objects may also be created by passing in a single sequence of coordinate or *Point* objects:

```
>>> ls = LineString(((0, 0), (1, 1)))
>>> ls = LineString([Point(0, 0), Point(1, 1)])
```

Empty `LineString` objects may be instantiated by passing no arguments or an empty sequence. The following are equivalent:

```
>>> ls = LineString()
>>> ls = LineString([])
```

closed

Returns whether or not this `LineString` is closed.

LinearRing

class `LinearRing(*args, **kwargs)`

`LinearRing` objects are constructed in the exact same way as *LineString* objects, however the coordinates must be closed, in other words, the first coordinates must be the same as the last coordinates. For example:

```
>>> ls = LinearRing((0, 0), (0, 1), (1, 1), (0, 0))
```

Notice that (0, 0) is the first and last coordinate –if they were not equal, an error would be raised.

is_counterclockwise

Returns whether this `LinearRing` is counterclockwise.

Polygon

```
class Polygon(*args, **kwargs)
```

Polygon objects may be instantiated by passing in parameters that represent the rings of the polygon. The parameters must either be *LinearRing* instances, or a sequence that may be used to construct a *LinearRing*:

```
>>> ext_coords = ((0, 0), (0, 1), (1, 1), (1, 0), (0, 0))
>>> int_coords = ((0.4, 0.4), (0.4, 0.6), (0.6, 0.6), (0.6, 0.4), (0.4, 0.4))
>>> poly = Polygon(ext_coords, int_coords)
>>> poly = Polygon(LinearRing(ext_coords), LinearRing(int_coords))
```

```
classmethod from_bbox(bbox)
```

Returns a polygon object from the given bounding-box, a 4-tuple comprising (xmin, ymin, xmax, ymax).

```
num_interior_rings
```

Returns the number of interior rings in this geometry.

Comparing Polygons

Note that it is possible to compare Polygon objects directly with < or >, but as the comparison is made through Polygon's *LineString*, it does not mean much (but is consistent and quick). You can always force the comparison with the *area* property:

```
>>> if poly_1.area > poly_2.area:
...     pass
...
```

Geometry Collections

MultiPoint

```
class MultiPoint(*args, **kwargs)
```

MultiPoint objects may be instantiated by passing in *Point* objects as arguments, or a single sequence of *Point* objects:

```
>>> mp = MultiPoint(Point(0, 0), Point(1, 1))
>>> mp = MultiPoint((Point(0, 0), Point(1, 1)))
```

MultiLineString

class MultiLineString(*args, **kwargs)

MultiLineString objects may be instantiated by passing in *LineString* objects as arguments, or a single sequence of *LineString* objects:

```
>>> ls1 = LineString((0, 0), (1, 1))
>>> ls2 = LineString((2, 2), (3, 3))
>>> mls = MultiLineString(ls1, ls2)
>>> mls = MultiLineString([ls1, ls2])
```

merged

Returns a *LineString* representing the line merge of all the components in this MultiLineString.

closed

Returns True if and only if all elements are closed.

MultiPolygon

class MultiPolygon(*args, **kwargs)

MultiPolygon objects may be instantiated by passing *Polygon* objects as arguments, or a single sequence of *Polygon* objects:

```
>>> p1 = Polygon(((0, 0), (0, 1), (1, 1), (0, 0)))
>>> p2 = Polygon(((1, 1), (1, 2), (2, 2), (1, 1)))
>>> mp = MultiPolygon(p1, p2)
>>> mp = MultiPolygon([p1, p2])
```

GeometryCollection

class GeometryCollection(*args, **kwargs)

GeometryCollection objects may be instantiated by passing in other *GEOSGeometry* as arguments, or a single sequence of *GEOSGeometry* objects:

```
>>> poly = Polygon(((0, 0), (0, 1), (1, 1), (0, 0)))
>>> gc = GeometryCollection(Point(0, 0), MultiPoint(Point(0, 0), Point(1, 1)), poly)
>>> gc = GeometryCollection((Point(0, 0), MultiPoint(Point(0, 0), Point(1, 1)), poly))
```

Prepared Geometries

In order to obtain a prepared geometry, access the `GEOSGeometry.prepared` property. Once you have a `PreparedGeometry` instance its spatial predicate methods, listed below, may be used with other `GEOSGeometry` objects. An operation with a prepared geometry can be orders of magnitude faster –the more complex the geometry that is prepared, the larger the speedup in the operation. For more information, please consult the [GEOS wiki page on prepared geometries](#).

For example:

```
>>> from django.contrib.gis.geos import Point, Polygon
>>> poly = Polygon.from_bbox((0, 0, 5, 5))
>>> prep_poly = poly.prepared
>>> prep_poly.contains(Point(2.5, 2.5))
True
```

PreparedGeometry

class PreparedGeometry

All methods on `PreparedGeometry` take an `other` argument, which must be a `GEOSGeometry` instance.

`contains(other)`

`contains_properly(other)`

`covers(other)`

`crosses(other)`

`disjoint(other)`

`intersects(other)`

`overlaps(other)`

`touches(other)`

`within(other)`

Geometry Factories

`fromfile(file_h)`

Parameters

`file_h` (a Python file object or a string path to the file) –input file that contains spatial data

Return type

a *GEOSGeometry* corresponding to the spatial data in the file

Example:

```
>>> from django.contrib.gis.geos import fromfile
>>> g = fromfile("/home/bob/geom.wkt")
```

`fromstr(string, srid=None)`

Parameters

- `string` (*str*) –string that contains spatial data
- `srid` (*int*) –spatial reference identifier

Return type

a *GEOSGeometry* corresponding to the spatial data in the string

`fromstr(string, srid)` is equivalent to *GEOSGeometry(string, srid)*.

Example:

```
>>> from django.contrib.gis.geos import fromstr
>>> pnt = fromstr("POINT(-90.5 29.5)", srid=4326)
```

I/O Objects

Reader Objects

The reader I/O classes return a *GEOSGeometry* instance from the WKB and/or WKT input given to their `read(geom)` method.

`class WKBReader`

Example:

```
>>> from django.contrib.gis.geos import WKBReader
>>> wkb_r = WKBReader()
>>> wkb_r.read("01010000000000000000F03F0000000000F03F")
<Point object at 0x103a88910>
```

`class WKTRReader`

Example:

```
>>> from django.contrib.gis.geos import WKTRReader
>>> wkt_r = WKTRReader()
>>> wkt_r.read("POINT(1 1)")
<Point object at 0x103a88b50>
```

Writer Objects

All writer objects have a `write(geom)` method that returns either the WKB or WKT of the given geometry. In addition, *WKBWriter* objects also have properties that may be used to change the byte order, and or include the SRID value (in other words, EWKB).

`class WKBWriter(dim=2)`

WKBWriter provides the most control over its output. By default it returns OGC-compliant WKB when its `write` method is called. However, it has properties that allow for the creation of EWKB, a superset of the WKB standard that includes additional information. See the *WKBWriter.outdim* documentation for more details about the `dim` argument.

`write(geom)`

Returns the WKB of the given geometry as a Python `buffer` object. Example:

```
>>> from django.contrib.gis.geos import Point, WKBWriter
>>> pnt = Point(1, 1)
>>> wkb_w = WKBWriter()
>>> wkb_w.write(pnt)
<read-only buffer for 0x103a898f0, size -1, offset 0 at 0x103a89930>
```

`write_hex(geom)`

Returns WKB of the geometry in hexadecimal. Example:

```
>>> from django.contrib.gis.geos import Point, WKBWriter
>>> pnt = Point(1, 1)
>>> wkb_w = WKBWriter()
>>> wkb_w.write_hex(pnt)
'010100000000000000000000F03F000000000000F03F'
```

`byteorder`

This property may be set to change the byte-order of the geometry representation.

Byteorder Value	Description
0	Big Endian (e.g., compatible with RISC systems)
1	Little Endian (e.g., compatible with x86 systems)

Example:

```
>>> from django.contrib.gis.geos import Point, WKBWriter
>>> wkb_w = WKBWriter()
>>> pnt = Point(1, 1)
>>> wkb_w.write_hex(pnt)
'010100000000000000000000F03F000000000000F03F'
>>> wkb_w.byteorder = 0
'00000000013FF00000000000003FF0000000000000'
```

outdim

This property may be set to change the output dimension of the geometry representation. In other words, if you have a 3D geometry then set to 3 so that the Z value is included in the WKB.

Outdim Value	Description
2	The default, output 2D WKB.
3	Output 3D WKB.

Example:

```
>>> from django.contrib.gis.geos import Point, WKBWriter
>>> wkb_w = WKBWriter()
>>> wkb_w.outdim
2
>>> pnt = Point(1, 1, 1)
>>> wkb_w.write_hex(pnt) # By default, no Z value included:
'010100000000000000000000F03F000000000000F03F'
>>> wkb_w.outdim = 3 # Tell writer to include Z values
>>> wkb_w.write_hex(pnt)
'010100008000000000000000F03F000000000000F03F000000000000F03F'
```

srid

Set this property with a boolean to indicate whether the SRID of the geometry should be included with the WKB representation. Example:

```
>>> from django.contrib.gis.geos import Point, WKBWriter
>>> wkb_w = WKBWriter()
>>> pnt = Point(1, 1, srid=4326)
>>> wkb_w.write_hex(pnt) # By default, no SRID included:
'010100000000000000000000F03F000000000000F03F'
>>> wkb_w.srid = True # Tell writer to include SRID
>>> wkb_w.write_hex(pnt)
'0101000020E610000000000000000000F03F000000000000F03F'
```

class `WKTWriter(dim=2, trim=False, precision=None)`

This class allows outputting the WKT representation of a geometry. See the `WKBWriter.outdim`, `trim`, and `precision` attributes for details about the constructor arguments.

write(geom)

Returns the WKT of the given geometry. Example:

```
>>> from django.contrib.gis.geos import Point, WKTWriter
>>> pnt = Point(1, 1)
>>> wkt_w = WKTWriter()
>>> wkt_w.write(pnt)
'POINT (1.0000000000000000 1.0000000000000000)'
```

outdim

See `WKBWriter.outdim`.

trim

This property is used to enable or disable trimming of unnecessary decimals.

```
>>> from django.contrib.gis.geos import Point, WKTWriter
>>> pnt = Point(1, 1)
>>> wkt_w = WKTWriter()
>>> wkt_w.trim
False
>>> wkt_w.write(pnt)
'POINT (1.0000000000000000 1.0000000000000000)'
>>> wkt_w.trim = True
>>> wkt_w.write(pnt)
'POINT (1 1)'
```

precision

This property controls the rounding precision of coordinates; if set to `None` rounding is disabled.

```
>>> from django.contrib.gis.geos import Point, WKTWriter
>>> pnt = Point(1.44, 1.66)
>>> wkt_w = WKTWriter()
>>> print(wkt_w.precision)
None
>>> wkt_w.write(pnt)
'POINT (1.4399999999999999 1.6599999999999999)'
>>> wkt_w.precision = 0
>>> wkt_w.write(pnt)
'POINT (1 2)'
>>> wkt_w.precision = 1
>>> wkt_w.write(pnt)
'POINT (1.4 1.7)'
```

Settings

GEOS_LIBRARY_PATH

A string specifying the location of the GEOS C library. Typically, this setting is only used if the GEOS C library is in a non-standard location (e.g., `/home/bob/lib/libgeos_c.so`).

Note: The setting must be the full path to the C shared library; in other words you want to use `libgeos_c.so`, not `libgeos.so`.

Exceptions

exception `GEOSException`

The base GEOS exception, indicates a GEOS-related error.

GDAL API

GDAL stands for Geospatial Data Abstraction Library, and is a veritable “Swiss army knife” of GIS data functionality. A subset of GDAL is the [OGR Simple Features Library](#), which specializes in reading and writing vector geographic data in a variety of standard formats.

GeoDjango provides a high-level Python interface for some of the capabilities of OGR, including the reading and coordinate transformation of vector spatial data and minimal support for GDAL’s features with respect to raster (image) data.

Note: Although the module is named `gdal`, GeoDjango only supports some of the capabilities of OGR and GDAL's raster features at this time.

Overview

Sample Data

The GDAL/OGR tools described here are designed to help you read in your geospatial data, in order for most of them to be useful you have to have some data to work with. If you're starting out and don't yet have any data of your own to use, GeoDjango tests contain a number of data sets that you can use for testing. You can download them here:

```
$ wget https://raw.githubusercontent.com/django/django/main/tests/gis_tests/data/cities/cities.  
→{shp,prj,shx,dbf}  
$ wget https://raw.githubusercontent.com/django/django/main/tests/gis_tests/data/rasters/raster.tif
```

Vector Data Source Objects

`DataSource`

DataSource is a wrapper for the OGR data source object that supports reading data from a variety of OGR-supported geospatial file formats and data sources using a consistent interface. Each data source is represented by a *DataSource* object which contains one or more layers of data. Each layer, represented by a *Layer* object, contains some number of geographic features (*Feature*), information about the type of features contained in that layer (e.g. points, polygons, etc.), as well as the names and types of any additional fields (*Field*) of data that may be associated with each feature in that layer.

```
class DataSource(ds_input, encoding='utf-8')
```

The constructor for `DataSource` only requires one parameter: the path of the file you want to read. However, OGR also supports a variety of more complex data sources, including databases, that may be accessed by passing a special name string instead of a path. For more information, see the [OGR Vector Formats](#) documentation. The *name* property of a `DataSource` instance gives the OGR name of the underlying data source that it is using.

The optional *encoding* parameter allows you to specify a non-standard encoding of the strings in the source. This is typically useful when you obtain `DjangoUnicodeDecodeError` exceptions while reading field values.

Once you've created your `DataSource`, you can find out how many layers of data it contains by accessing the *layer_count* property, or (equivalently) by using the `len()` function. For information on accessing the layers of data themselves, see the next section:

```
>>> from django.contrib.gis.gdal import DataSource
>>> ds = DataSource("/path/to/your/cities.shp")
>>> ds.name
'/path/to/your/cities.shp'
>>> ds.layer_count  # This file only contains one layer
1
```

layer_count

Returns the number of layers in the data source.

name

Returns the name of the data source.

Layer

class Layer

Layer is a wrapper for a layer of data in a **DataSource** object. You never create a **Layer** object directly. Instead, you retrieve them from a **DataSource** object, which is essentially a standard Python container of **Layer** objects. For example, you can access a specific layer by its index (e.g. `ds[0]` to access the first layer), or you can iterate over all the layers in the container in a `for` loop. The **Layer** itself acts as a container for geometric features.

Typically, all the features in a given layer have the same geometry type. The `geom_type` property of a layer is an *OGRGeomType* that identifies the feature type. We can use it to print out some basic information about each layer in a **DataSource**:

```
>>> for layer in ds:
...     print('Layer "%s": %i %ss' % (layer.name, len(layer), layer.geom_type.name))
...
Layer "cities": 3 Points
```

The example output is from the cities data source, loaded above, which evidently contains one layer, called "cities", which contains three point features. For simplicity, the examples below assume that you've stored that layer in the variable `layer`:

```
>>> layer = ds[0]
```

name

Returns the name of this layer in the data source.

```
>>> layer.name
'cities'
```

num_feat

Returns the number of features in the layer. Same as `len(layer)`:

```
>>> layer.num_feat
3
```

geom_type

Returns the geometry type of the layer, as an *OGRGeomType* object:

```
>>> layer.geom_type.name
'Point'
```

num_fields

Returns the number of fields in the layer, i.e the number of fields of data associated with each feature in the layer:

```
>>> layer.num_fields
4
```

fields

Returns a list of the names of each of the fields in this layer:

```
>>> layer.fields
['Name', 'Population', 'Density', 'Created']
```

Returns a list of the data types of each of the fields in this layer. These are subclasses of `Field`, discussed below:

```
>>> [ft.__name__ for ft in layer.field_types]
['OFTString', 'OFTReal', 'OFTReal', 'OFTDate']
```

field_widths

Returns a list of the maximum field widths for each of the fields in this layer:

```
>>> layer.field_widths
[80, 11, 24, 10]
```

field_precisions

Returns a list of the numeric precisions for each of the fields in this layer. This is meaningless (and set to zero) for non-numeric fields:

```
>>> layer.field_precisions
[0, 0, 15, 0]
```

extent

Returns the spatial extent of this layer, as an *Envelope* object:

```
>>> layer.extent.tuple
(-104.609252, 29.763374, -95.23506, 38.971823)
```

srs

Property that returns the *SpatialReference* associated with this layer:

```
>>> print(layer.srs)
GEOGCS["GCS_WGS_1984",
  DATUM["WGS_1984",
    SPHEROID["WGS_1984",6378137,298.257223563]],
  PRIMEM["Greenwich",0],
  UNIT["Degree",0.017453292519943295]]
```

If the *Layer* has no spatial reference information associated with it, *None* is returned.

spatial_filter

Property that may be used to retrieve or set a spatial filter for this layer. A spatial filter can only be set with an *OGREGeometry* instance, a 4-tuple extent, or *None*. When set with something other than *None*, only features that intersect the filter will be returned when iterating over the layer:

```
>>> print(layer.spatial_filter)
None
>>> print(len(layer))
3
>>> [feat.get("Name") for feat in layer]
['Pueblo', 'Lawrence', 'Houston']
>>> ks_extent = (-102.051, 36.99, -94.59, 40.00) # Extent for state of Kansas
>>> layer.spatial_filter = ks_extent
>>> len(layer)
1
>>> [feat.get("Name") for feat in layer]
['Lawrence']
>>> layer.spatial_filter = None
>>> len(layer)
3
```

get_fields()

A method that returns a list of the values of a given field for each feature in the layer:

```
>>> layer.get_fields("Name")
['Pueblo', 'Lawrence', 'Houston']
```

get_geoms(geos=False)

A method that returns a list containing the geometry of each feature in the layer. If the optional argument `geos` is set to `True` then the geometries are converted to *GEOSGeometry* objects. Otherwise, they are returned as *OGRGeometry* objects:

```
>>> [pt.tuple for pt in layer.get_geoms()]
[(-104.609252, 38.255001), (-95.23506, 38.971823), (-95.363151, 29.763374)]
```

test_capability(capability)

Returns a boolean indicating whether this layer supports the given capability (a string). Examples of valid capability strings include: 'RandomRead', 'SequentialWrite', 'RandomWrite', 'FastSpatialFilter', 'FastFeatureCount', 'FastGetExtent', 'CreateField', 'Transactions', 'DeleteFeature', and 'FastSetNextByIndex'.

Feature

class Feature

Feature wraps an OGR feature. You never create a **Feature** object directly. Instead, you retrieve them from a *Layer* object. Each feature consists of a geometry and a set of fields containing additional properties. The geometry of a field is accessible via its `geom` property, which returns an *OGRGeometry* object. A **Feature** behaves like a standard Python container for its fields, which it returns as *Field* objects: you can access a field directly by its index or name, or you can iterate over a feature's fields, e.g. in a `for` loop.

geom

Returns the geometry for this feature, as an *OGRGeometry* object:

```
>>> city.geom.tuple
(-104.609252, 38.255001)
```

get

A method that returns the value of the given field (specified by name) for this feature, not a *Field* wrapper object:

```
>>> city.get("Population")
102121
```

geom_type

Returns the type of geometry for this feature, as an *OGRGeomType* object. This will be the same for all features in a given layer and is equivalent to the *Layer.geom_type* property of the *Layer* object the feature came from.

num_fields

Returns the number of fields of data associated with the feature. This will be the same for all features in a given layer and is equivalent to the *Layer.num_fields* property of the *Layer* object the feature came from.

fields

Returns a list of the names of the fields of data associated with the feature. This will be the same for all features in a given layer and is equivalent to the *Layer.fields* property of the *Layer* object the feature came from.

fid

Returns the feature identifier within the layer:

```
>>> city.fid
0
```

layer_name

Returns the name of the *Layer* that the feature came from. This will be the same for all features in a given layer:

```
>>> city.layer_name
'cities'
```

index

A method that returns the index of the given field name. This will be the same for all features in a given layer:

```
>>> city.index("Population")
1
```

Field

class Field

name

Returns the name of this field:

```
>>> city["Name"].name
'Name'
```

type

Returns the OGR type of this field, as an integer. The `FIELD_CLASSES` dictionary maps these values onto subclasses of `Field`:

```
>>> city["Density"].type
2
```

type_name

Returns a string with the name of the data type of this field:

```
>>> city["Name"].type_name
'String'
```

value

Returns the value of this field. The `Field` class itself returns the value as a string, but each subclass returns the value in the most appropriate form:

```
>>> city["Population"].value
102121
```

width

Returns the width of this field:

```
>>> city["Name"].width
80
```

precision

Returns the numeric precision of this field. This is meaningless (and set to zero) for non-numeric fields:

```
>>> city["Density"].precision
15
```

as_double()

Returns the value of the field as a double (float):

```
>>> city["Density"].as_double()
874.7
```

as_int()

Returns the value of the field as an integer:

```
>>> city["Population"].as_int()
102121
```

as_string()

Returns the value of the field as a string:

```
>>> city["Name"].as_string()
'Pueblo'
```

as_datetime()

Returns the value of the field as a tuple of date and time components:

```
>>> city["Created"].as_datetime()
(c_long(1999), c_long(5), c_long(23), c_long(0), c_long(0), c_long(0), c_long(0))
```

Driver

class Driver(dr_input)

The `Driver` class is used internally to wrap an OGR *DataSource* driver.

driver_count

Returns the number of OGR vector drivers currently registered.

OGR Geometries

OGRGeometry

OGRGeometry objects share similar functionality with *GEOSGeometry* objects and are thin wrappers around OGR's internal geometry representation. Thus, they allow for more efficient access to data when using *DataSource*. Unlike its GEOS counterpart, *OGRGeometry* supports spatial reference systems and coordinate transformation:

```
>>> from django.contrib.gis.gdal import OGRGeometry
>>> polygon = OGRGeometry("POLYGON((0 0, 5 0, 5 5, 0 5))")
```

class `OGRGeometry`(geom_input, srs=None)

This object is a wrapper for the `OGR Geometry` class. These objects are instantiated directly from the given `geom_input` parameter, which may be a string containing WKT, HEX, GeoJSON, a buffer containing WKB data, or an `OGRGeomType` object. These objects are also returned from the `Feature.geom` attribute, when reading vector data from `Layer` (which is in turn a part of a `DataSource`).

classmethod `from_gml`(gml_string)

Constructs an `OGRGeometry` from the given GML string.

classmethod `from_bbox`(bbox)

Constructs a `Polygon` from the given bounding-box (a 4-tuple).

__len__()

Returns the number of points in a `LineString`, the number of rings in a `Polygon`, or the number of geometries in a `GeometryCollection`. Not applicable to other geometry types.

__iter__()

Iterates over the points in a `LineString`, the rings in a `Polygon`, or the geometries in a `GeometryCollection`. Not applicable to other geometry types.

__getitem__()

Returns the point at the specified index for a `LineString`, the interior ring at the specified index for a `Polygon`, or the geometry at the specified index in a `GeometryCollection`. Not applicable to other geometry types.

dimension

Returns the number of coordinated dimensions of the geometry, i.e. 0 for points, 1 for lines, and so forth:

```
>> polygon.dimension
2
```

coord_dim

Returns or sets the coordinate dimension of this geometry. For example, the value would be 2 for two-dimensional geometries.

geom_count

Returns the number of elements in this geometry:

```
>>> polygon.geom_count
1
```

point_count

Returns the number of points used to describe this geometry:

```
>>> polygon.point_count
4
```

num_points

Alias for *point_count*.

num_coords

Alias for *point_count*.

geom_type

Returns the type of this geometry, as an *OGRGeomType* object.

geom_name

Returns the name of the type of this geometry:

```
>>> polygon.geom_name
'POLYGON'
```

area

Returns the area of this geometry, or 0 for geometries that do not contain an area:

```
>>> polygon.area
25.0
```

envelope

Returns the envelope of this geometry, as an *Envelope* object.

extent

Returns the envelope of this geometry as a 4-tuple, instead of as an *Envelope* object:

```
>>> point.extent
(0.0, 0.0, 5.0, 5.0)
```

srs

This property controls the spatial reference for this geometry, or `None` if no spatial reference system has been assigned to it. If assigned, accessing this property returns a *SpatialReference* object. It may be set with another *SpatialReference* object, or any input that *SpatialReference* accepts. Example:

```
>>> city.geom.srs.name
'GCS_WGS_1984'
```

srid

Returns or sets the spatial reference identifier corresponding to *SpatialReference* of this geometry. Returns `None` if there is no spatial reference information associated with this geometry, or if an SRID cannot be determined.

geos

Returns a *GEOSGeometry* object corresponding to this geometry.

gml

Returns a string representation of this geometry in GML format:

```
>>> OGRGeometry("POINT(1 2)").gml
'<gml:Point><gml:coordinates>1,2</gml:coordinates></gml:Point>'
```

hex

Returns a string representation of this geometry in HEX WKB format:

```
>>> OGRGeometry("POINT(1 2)").hex
'010100000000000000000000F03F00000000000040'
```

json

Returns a string representation of this geometry in JSON format:

```
>>> OGRGeometry("POINT(1 2)").json
'{"type": "Point", "coordinates": [ 1.000000, 2.000000 ] }'
```

kml

Returns a string representation of this geometry in KML format.

wkb_size

Returns the size of the WKB buffer needed to hold a WKB representation of this geometry:

```
>>> OGRGeometry("POINT(1 2)").wkb_size
21
```

wkb

Returns a `buffer` containing a WKB representation of this geometry.

wkt

Returns a string representation of this geometry in WKT format.

ewkt

Returns the EWKT representation of this geometry.

clone()

Returns a new *OGRGeometry* clone of this geometry object.

close_rings()

If there are any rings within this geometry that have not been closed, this routine will do so by adding the starting point to the end:

```
>>> triangle = OGRGeometry("LINEARRING (0 0,0 1,1 0)")
>>> triangle.close_rings()
>>> triangle.wkt
'LINEARRING (0 0,0 1,1 0,0 0)'
```

transform(coord_trans, clone=False)

Transforms this geometry to a different spatial reference system. May take a *CoordTransform* object, a *SpatialReference* object, or any other input accepted by *SpatialReference* (including spatial reference WKT and PROJ strings, or an integer SRID).

By default nothing is returned and the geometry is transformed in-place. However, if the `clone` keyword is set to `True` then a transformed clone of this geometry is returned instead.

intersects(other)

Returns `True` if this geometry intersects the other, otherwise returns `False`.

equals(other)

Returns `True` if this geometry is equivalent to the other, otherwise returns `False`.

disjoint(other)

Returns `True` if this geometry is spatially disjoint to (i.e. does not intersect) the other, otherwise returns `False`.

touches(other)

Returns `True` if this geometry touches the other, otherwise returns `False`.

crosses(other)

Returns `True` if this geometry crosses the other, otherwise returns `False`.

within(other)

Returns `True` if this geometry is contained within the other, otherwise returns `False`.

contains(other)

Returns `True` if this geometry contains the other, otherwise returns `False`.

overlaps(other)

Returns `True` if this geometry overlaps the other, otherwise returns `False`.

boundary()

The boundary of this geometry, as a new *OGRGeometry* object.

convex_hull

The smallest convex polygon that contains this geometry, as a new *OGRGeometry* object.

difference()

Returns the region consisting of the difference of this geometry and the other, as a new *OGRGeometry* object.

intersection()

Returns the region consisting of the intersection of this geometry and the other, as a new *OGRGeometry* object.

sym_difference()

Returns the region consisting of the symmetric difference of this geometry and the other, as a new *OGRGeometry* object.

union()

Returns the region consisting of the union of this geometry and the other, as a new *OGRGeometry* object.

tuple

Returns the coordinates of a point geometry as a tuple, the coordinates of a line geometry as a tuple of tuples, and so forth:

```
>>> OGRGeometry("POINT (1 2)").tuple
(1.0, 2.0)
>>> OGRGeometry("LINESTRING (1 2,3 4)").tuple
((1.0, 2.0), (3.0, 4.0))
```

`coords`

An alias for *tuple*.

`class Point`

`x`

Returns the X coordinate of this point:

```
>>> OGRGeometry("POINT (1 2)").x
1.0
```

`y`

Returns the Y coordinate of this point:

```
>>> OGRGeometry("POINT (1 2)").y
2.0
```

`z`

Returns the Z coordinate of this point, or `None` if the point does not have a Z coordinate:

```
>>> OGRGeometry("POINT (1 2 3)").z
3.0
```

`class LineString`

`x`

Returns a list of X coordinates in this line:

```
>>> OGRGeometry("LINESTRING (1 2,3 4)").x
[1.0, 3.0]
```

`y`

Returns a list of Y coordinates in this line:

```
>>> OGRGeometry("LINESTRING (1 2,3 4)").y
[2.0, 4.0]
```

`z`

Returns a list of Z coordinates in this line, or `None` if the line does not have Z coordinates:

```
>>> OGRGeometry("LINESTRING (1 2 3,4 5 6)").z
[3.0, 6.0]
```

```
class Polygon
```

```
    shell
```

Returns the shell or exterior ring of this polygon, as a `LinearRing` geometry.

```
    exterior_ring
```

An alias for *shell*.

```
    centroid
```

Returns a *Point* representing the centroid of this polygon.

```
class GeometryCollection
```

```
    add(geom)
```

Adds a geometry to this geometry collection. Not applicable to other geometry types.

`OGRGeomType`

```
class OGRGeomType(type_input)
```

This class allows for the representation of an OGR geometry type in any of several ways:

```
>>> from django.contrib.gis.gdal import OGRGeomType
>>> gt1 = OGRGeomType(3) # Using an integer for the type
>>> gt2 = OGRGeomType("Polygon") # Using a string
>>> gt3 = OGRGeomType("POLYGON") # It's case-insensitive
>>> print(gt1 == 3, gt1 == "Polygon") # Equivalence works w/non-OGRGeomType objects
True True
```

```
    name
```

Returns a short-hand string form of the OGR Geometry type:

```
>>> gt1.name
'Polygon'
```

```
    num
```

Returns the number corresponding to the OGR geometry type:

```
>>> gt1.num
3
```

```
    django
```

Returns the Django field type (a subclass of `GeometryField`) to use for storing this OGR type, or `None` if there is no appropriate Django type:

```
>>> gt1.django
'PolygonField'
```

Envelope

class `Envelope(*args)`

Represents an OGR Envelope structure that contains the minimum and maximum X, Y coordinates for a rectangle bounding box. The naming of the variables is compatible with the OGR Envelope C structure.

min_x

The value of the minimum X coordinate.

min_y

The value of the maximum X coordinate.

max_x

The value of the minimum Y coordinate.

max_y

The value of the maximum Y coordinate.

ur

The upper-right coordinate, as a tuple.

ll

The lower-left coordinate, as a tuple.

tuple

A tuple representing the envelope.

wkt

A string representing this envelope as a polygon in WKT format.

expand_to_include(*args)

Coordinate System Objects

SpatialReference

`class SpatialReference(srs_input)`

Spatial reference objects are initialized on the given `srs_input`, which may be one of the following:

- OGC Well Known Text (WKT) (a string)
- EPSG code (integer or string)
- PROJ string
- A shorthand string for well-known standards ('WGS84', 'WGS72', 'NAD27', 'NAD83')

Example:

```
>>> wgs84 = SpatialReference("WGS84") # shorthand string
>>> wgs84 = SpatialReference(4326) # EPSG code
>>> wgs84 = SpatialReference("EPSG:4326") # EPSG string
>>> proj = "+proj=longlat +ellps=WGS84 +datum=WGS84 +no_defs "
>>> wgs84 = SpatialReference(proj) # PROJ string
>>> wgs84 = SpatialReference(
...     """GEOGCS["WGS 84",
...     DATUM["WGS_1984",
...         SPHEROID["WGS 84",6378137,298.257223563,
...         AUTHORITY["EPSG","7030"]],
...         AUTHORITY["EPSG","6326"]],
...     PRIMEM["Greenwich",0,
...         AUTHORITY["EPSG","8901"]],
...     UNIT["degree",0.01745329251994328,
...         AUTHORITY["EPSG","9122"]],
...     AUTHORITY["EPSG","4326"]] """
... ) # OGC WKT
```

`__getitem__(target)`

Returns the value of the given string attribute node, `None` if the node doesn't exist. Can also take a tuple as a parameter, (target, child), where child is the index of the attribute in the WKT. For example:

```
>>> wkt = 'GEOGCS["WGS 84", DATUM["WGS_1984", ... AUTHORITY["EPSG","4326"]]'
>>> srs = SpatialReference(wkt) # could also use 'WGS84', or 4326
>>> print(srs["GEOGCS"])
WGS 84
>>> print(srs["DATUM"])
WGS_1984
>>> print(srs["AUTHORITY"])
```

(continues on next page)

(continued from previous page)

```
EPSG
>>> print(srs["AUTHORITY", 1]) # The authority value
4326
>>> print(srs["TOWGS84", 4]) # the fourth value in this wkt
0
>>> print(srs["UNIT|AUTHORITY"]) # For the units authority, have to use the pipe symbol.
EPSG
>>> print(srs["UNIT|AUTHORITY", 1]) # The authority value for the units
9122
```

attr_value(target, index=0)

The attribute value for the given target node (e.g. 'PROJCS'). The index keyword specifies an index of the child node to return.

auth_name(target)

Returns the authority name for the given string target node.

auth_code(target)

Returns the authority code for the given string target node.

clone()

Returns a clone of this spatial reference object.

identify_epsg()

This method inspects the WKT of this `SpatialReference` and will add EPSG authority nodes where an EPSG identifier is applicable.

from_esri()

Morphs this `SpatialReference` from ESRI's format to EPSG

to_esri()

Morphs this `SpatialReference` to ESRI's format.

validate()

Checks to see if the given spatial reference is valid, if not an exception will be raised.

import_epsg(epsg)

Import spatial reference from EPSG code.

import_proj(proj)

Import spatial reference from PROJ string.

```
import_user_input(user_input)
```

```
import_wkt(wkt)
```

Import spatial reference from WKT.

```
import_xml(xml)
```

Import spatial reference from XML.

```
name
```

Returns the name of this Spatial Reference.

```
srid
```

Returns the SRID of top-level authority, or None if undefined.

```
linear_name
```

Returns the name of the linear units.

```
linear_units
```

Returns the value of the linear units.

```
angular_name
```

Returns the name of the angular units.”

```
angular_units
```

Returns the value of the angular units.

```
units
```

Returns a 2-tuple of the units value and the units name and will automatically determines whether to return the linear or angular units.

```
ellipsoid
```

Returns a tuple of the ellipsoid parameters for this spatial reference: (semimajor axis, semiminor axis, and inverse flattening).

```
semi_major
```

Returns the semi major axis of the ellipsoid for this spatial reference.

```
semi_minor
```

Returns the semi minor axis of the ellipsoid for this spatial reference.

```
inverse_flattening
```

Returns the inverse flattening of the ellipsoid for this spatial reference.

geographic

Returns True if this spatial reference is geographic (root node is GEOGCS).

local

Returns True if this spatial reference is local (root node is LOCAL_CS).

projected

Returns True if this spatial reference is a projected coordinate system (root node is PROJCS).

wkt

Returns the WKT representation of this spatial reference.

pretty_wkt

Returns the ‘pretty’ representation of the WKT.

proj

Returns the PROJ representation for this spatial reference.

proj4

Alias for *SpatialReference.proj*.

xml

Returns the XML representation of this spatial reference.

CoordTransform

class CoordTransform(source, target)

Represents a coordinate system transform. It is initialized with two *SpatialReference*, representing the source and target coordinate systems, respectively. These objects should be used when performing the same coordinate transformation repeatedly on different geometries:

```
>>> ct = CoordTransform(SpatialReference("WGS84"), SpatialReference("NAD83"))
>>> for feat in layer:
...     geom = feat.geom # getting clone of feature geometry
...     geom.transform(ct) # transforming
... 
```

Raster Data Objects

GDALRaster

GDALRaster is a wrapper for the GDAL raster source object that supports reading data from a variety of GDAL-supported geospatial file formats and data sources using a consistent interface. Each data source is represented by a *GDALRaster* object which contains one or more layers of data named bands. Each band, represented by a *GDALBand* object, contains georeferenced image data. For example, an RGB image is represented as three bands: one for red, one for green, and one for blue.

Note: For raster data there is no difference between a raster instance and its data source. Unlike for the Geometry objects, *GDALRaster* objects are always a data source. Temporary rasters can be instantiated in memory using the corresponding driver, but they will be of the same class as file-based raster sources.

class GDALRaster(ds_input, write=False)

The constructor for *GDALRaster* accepts two parameters. The first parameter defines the raster source, and the second parameter defines if a raster should be opened in write mode. For newly-created rasters, the second parameter is ignored and the new raster is always created in write mode.

The first parameter can take three forms: a string or [Path](#) representing a file path (filesystem or GDAL virtual filesystem), a dictionary with values defining a new raster, or a bytes object representing a raster file.

If the input is a file path, the raster is opened from there. If the input is raw data in a dictionary, the parameters `width`, `height`, and `srid` are required. If the input is a bytes object, it will be opened using a GDAL virtual filesystem.

For a detailed description of how to create rasters using dictionary input, see [Creating rasters from data](#). For a detailed description of how to create rasters in the virtual filesystem, see [Using GDAL's Virtual Filesystem](#).

The following example shows how rasters can be created from different input sources (using the sample data from the GeoDjango tests; see also the [Sample Data](#) section).

```
>>> from django.contrib.gis.gdal import GDALRaster
>>> rst = GDALRaster('/path/to/your/raster.tif', write=False)
>>> rst.name
'/path/to/your/raster.tif'
>>> rst.width, rst.height # This file has 163 x 174 pixels
(163, 174)
>>> rst = GDALRaster({ # Creates an in-memory raster
...     'srid': 4326,
...     'width': 4,
```

(continues on next page)

(continued from previous page)

```

...     'height': 4,
...     'datatype': 1,
...     'bands': [{
...         'data': (2, 3),
...         'offset': (1, 1),
...         'size': (2, 2),
...         'shape': (2, 1),
...         'nodata_value': 5,
...     }]
... })
>>> rst.srs.srid
4326
>>> rst.width, rst.height
(4, 4)
>>> rst.bands[0].data()
array([[5, 5, 5, 5],
       [5, 2, 3, 5],
       [5, 2, 3, 5],
       [5, 5, 5, 5]], dtype=uint8)
>>> rst_file = open('/path/to/your/raster.tif', 'rb')
>>> rst_bytes = rst_file.read()
>>> rst = GDALRaster(rst_bytes)
>>> rst.is_vsi_based
True
>>> rst.name # Stored in a random path in the vsimem filesystem.
'/vsimem/da300bdb-129d-49a8-b336-e410a9428dad'

```

Support for `pathlib.Path` `ds_input` was added.

name

The name of the source which is equivalent to the input file path or the name provided upon instantiation.

```

>>> GDALRaster({'width': 10, 'height': 10, 'name': 'myraster', 'srid': 4326}).name
'myraster'

```

driver

The name of the GDAL driver used to handle the input file. For `GDALRasters` created from a file, the driver type is detected automatically. The creation of rasters from scratch is an in-memory raster by default ('MEM'), but can be altered as needed. For instance, use `GTiff` for a GeoTiff file. For a list of file types, see also the [GDAL Raster Formats](#) list.

An in-memory raster is created through the following example:

```
>>> GDALRaster({'width': 10, 'height': 10, 'srid': 4326}).driver.name
'MEM'
```

A file based GeoTiff raster is created through the following example:

```
>>> import tempfile
>>> rstfile = tempfile.NamedTemporaryFile(suffix='.tif')
>>> rst = GDALRaster({'driver': 'GTiff', 'name': rstfile.name, 'srid': 4326,
...                  'width': 255, 'height': 255, 'nr_of_bands': 1})
>>> rst.name
'/tmp/tmp7x9H4J.tif'          # The exact filename will be different on your computer
>>> rst.driver.name
'GTiff'
```

width

The width of the source in pixels (X-axis).

```
>>> GDALRaster({'width': 10, 'height': 20, 'srid': 4326}).width
10
```

height

The height of the source in pixels (Y-axis).

```
>>> GDALRaster({'width': 10, 'height': 20, 'srid': 4326}).height
20
```

srs

The spatial reference system of the raster, as a *SpatialReference* instance. The SRS can be changed by setting it to an other *SpatialReference* or providing any input that is accepted by the *SpatialReference* constructor.

```
>>> rst = GDALRaster({'width': 10, 'height': 20, 'srid': 4326})
>>> rst.srs.srid
4326
>>> rst.srs = 3086
>>> rst.srs.srid
3086
```

srid

The Spatial Reference System Identifier (SRID) of the raster. This property is a shortcut to getting or setting the SRID through the *srs* attribute.

```
>>> rst = GDALRaster({'width': 10, 'height': 20, 'srid': 4326})
>>> rst.srid
```

(continues on next page)

(continued from previous page)

```
4326
>>> rst.srid = 3086
>>> rst.srid
3086
>>> rst.srs.srid # This is equivalent
3086
```

geotransform

The affine transformation matrix used to georeference the source, as a tuple of six coefficients which map pixel/line coordinates into georeferenced space using the following relationship:

```
Xgeo = GT(0) + Xpixel * GT(1) + Yline * GT(2)
Ygeo = GT(3) + Xpixel * GT(4) + Yline * GT(5)
```

The same values can be retrieved by accessing the *origin* (indices 0 and 3), *scale* (indices 1 and 5) and *skew* (indices 2 and 4) properties.

The default is [0.0, 1.0, 0.0, 0.0, 0.0, -1.0].

```
>>> rst = GDALRaster({'width': 10, 'height': 20, 'srid': 4326})
>>> rst.geotransform
[0.0, 1.0, 0.0, 0.0, 0.0, -1.0]
```

origin

Coordinates of the top left origin of the raster in the spatial reference system of the source, as a point object with x and y members.

```
>>> rst = GDALRaster({'width': 10, 'height': 20, 'srid': 4326})
>>> rst.origin
[0.0, 0.0]
>>> rst.origin.x = 1
>>> rst.origin
[1.0, 0.0]
```

scale

Pixel width and height used for georeferencing the raster, as a point object with x and y members. See *geotransform* for more information.

```
>>> rst = GDALRaster({'width': 10, 'height': 20, 'srid': 4326})
>>> rst.scale
[1.0, -1.0]
>>> rst.scale.x = 2
>>> rst.scale
[2.0, -1.0]
```

skew

Skew coefficients used to georeference the raster, as a point object with `x` and `y` members. In case of north up images, these coefficients are both 0.

```
>>> rst = GDALRaster({'width': 10, 'height': 20, 'srid': 4326})
>>> rst.skew
[0.0, 0.0]
>>> rst.skew.x = 3
>>> rst.skew
[3.0, 0.0]
```

extent

Extent (boundary values) of the raster source, as a 4-tuple (`xmin`, `ymin`, `xmax`, `ymax`) in the spatial reference system of the source.

```
>>> rst = GDALRaster({'width': 10, 'height': 20, 'srid': 4326})
>>> rst.extent
(0.0, -20.0, 10.0, 0.0)
>>> rst.origin.x = 100
>>> rst.extent
(100.0, -20.0, 110.0, 0.0)
```

bands

List of all bands of the source, as *GDALBand* instances.

```
>>> rst = GDALRaster({'width': 1, "height": 2, 'srid': 4326,
...                  "bands": [{"data": [0, 1]}, {"data": [2, 3]}]})
>>> len(rst.bands)
2
>>> rst.bands[1].data()
array([[ 2.,  3.]], dtype=float32)
```

warp(`ds_input`, `resampling='NearestNeighbour'`, `max_error=0.0`)

Returns a warped version of this raster.

The warping parameters can be specified through the `ds_input` argument. The use of `ds_input` is analogous to the corresponding argument of the class constructor. It is a dictionary with the characteristics of the target raster. Allowed dictionary key values are `width`, `height`, `SRID`, `origin`, `scale`, `skew`, `datatype`, `driver`, and `name` (filename).

By default, the warp functions keeps most parameters equal to the values of the original source raster, so only parameters that should be changed need to be specified. Note that this includes the driver, so for file-based rasters the warp function will create a new raster on disk.

The only parameter that is set differently from the source raster is the name. The default value of

the raster name is the name of the source raster appended with `'_copy' + source_driver_name`. For file-based rasters it is recommended to provide the file path of the target raster.

The resampling algorithm used for warping can be specified with the `resampling` argument. The default is `NearestNeighbor`, and the other allowed values are `Bilinear`, `Cubic`, `CubicSpline`, `Lanczos`, `Average`, and `Mode`.

The `max_error` argument can be used to specify the maximum error measured in input pixels that is allowed in approximating the transformation. The default is 0.0 for exact calculations.

For users familiar with GDAL, this function has a similar functionality to the `gdalwarp` command-line utility.

For example, the warp function can be used for aggregating a raster to the double of its original pixel scale:

```
>>> rst = GDALRaster({
...     "width": 6, "height": 6, "srid": 3086,
...     "origin": [500000, 400000],
...     "scale": [100, -100],
...     "bands": [{"data": range(36), "nodata_value": 99}]
... })
>>> target = rst.warp({"scale": [200, -200], "width": 3, "height": 3})
>>> target.bands[0].data()
array([[ 7.,  9., 11.],
       [19., 21., 23.],
       [31., 33., 35.]], dtype=float32)
```

transform(srs, driver=None, name=None, resampling='NearestNeighbour', max_error=0.0)

Transforms this raster to a different spatial reference system (`srs`), which may be a *SpatialReference* object, or any other input accepted by *SpatialReference* (including spatial reference WKT and PROJ strings, or an integer SRID).

It calculates the bounds and scale of the current raster in the new spatial reference system and warps the raster using the *warp* function.

By default, the driver of the source raster is used and the name of the raster is the original name appended with `'_copy' + source_driver_name`. A different driver or name can be specified with the `driver` and `name` arguments.

The default resampling algorithm is `NearestNeighbour` but can be changed using the `resampling` argument. The default maximum allowed error for resampling is 0.0 and can be changed using the `max_error` argument. Consult the *warp* documentation for detail on those arguments.

```
>>> rst = GDALRaster({
...     "width": 6, "height": 6, "srid": 3086,
...     "origin": [500000, 400000],
```

(continues on next page)

(continued from previous page)

```

...     "scale": [100, -100],
...     "bands": [{"data": range(36), "nodata_value": 99}]
... })
>>> target_srs = SpatialReference(4326)
>>> target = rst.transform(target_srs)
>>> target.origin
[-82.98492744885776, 27.601924753080144]

```

info

Returns a string with a summary of the raster. This is equivalent to the `gdalinfo` command line utility.

metadata

The metadata of this raster, represented as a nested dictionary. The first-level key is the metadata domain. The second-level contains the metadata item names and values from each domain.

To set or update a metadata item, pass the corresponding metadata item to the method using the nested structure described above. Only keys that are in the specified dictionary are updated; the rest of the metadata remains unchanged.

To remove a metadata item, use `None` as the metadata value.

```

>>> rst = GDALRaster({'width': 10, 'height': 20, 'srid': 4326})
>>> rst.metadata
{}
>>> rst.metadata = {'DEFAULT': {'OWNER': 'Django', 'VERSION': '1.0'}}
>>> rst.metadata
{'DEFAULT': {'OWNER': 'Django', 'VERSION': '1.0'}}
>>> rst.metadata = {'DEFAULT': {'OWNER': None, 'VERSION': '2.0'}}
>>> rst.metadata
{'DEFAULT': {'VERSION': '2.0'}}

```

vsi_buffer

A bytes representation of this raster. Returns `None` for rasters that are not stored in GDAL's virtual filesystem.

is_vsi_based

A boolean indicating if this raster is stored in GDAL's virtual filesystem.

GDALBand

class GDALBand

GDALBand instances are not created explicitly, but rather obtained from a *GDALRaster* object, through its *bands* attribute. The GDALBands contain the actual pixel values of the raster.

description

The name or description of the band, if any.

width

The width of the band in pixels (X-axis).

height

The height of the band in pixels (Y-axis).

pixel_count

The total number of pixels in this band. Is equal to `width * height`.

statistics(refresh=False, approximate=False)

Compute statistics on the pixel values of this band. The return value is a tuple with the following structure: (minimum, maximum, mean, standard deviation).

If the `approximate` argument is set to `True`, the statistics may be computed based on overviews or a subset of image tiles.

If the `refresh` argument is set to `True`, the statistics will be computed from the data directly, and the cache will be updated with the result.

If a persistent cache value is found, that value is returned. For raster formats using Persistent Auxiliary Metadata (PAM) services, the statistics might be cached in an auxiliary file. In some cases this metadata might be out of sync with the pixel values or cause values from a previous call to be returned which don't reflect the value of the `approximate` argument. In such cases, use the `refresh` argument to get updated values and store them in the cache.

For empty bands (where all pixel values are “no data”), all statistics are returned as `None`.

The statistics can also be retrieved directly by accessing the *min*, *max*, *mean*, and *std* properties.

min

The minimum pixel value of the band (excluding the “no data” value).

max

The maximum pixel value of the band (excluding the “no data” value).

mean

The mean of all pixel values of the band (excluding the “no data” value).

std

The standard deviation of all pixel values of the band (excluding the “no data” value).

nodata_value

The “no data” value for a band is generally a special marker value used to mark pixels that are not valid data. Such pixels should generally not be displayed, nor contribute to analysis operations.

To delete an existing “no data” value, set this property to `None`.

datatype(as_string=False)

The data type contained in the band, as an integer constant between 0 (Unknown) and 11. If `as_string` is `True`, the data type is returned as a string with the following possible values: `GDT_Unknown`, `GDT_Byte`, `GDT_UInt16`, `GDT_Int16`, `GDT_UInt32`, `GDT_Int32`, `GDT_Float32`, `GDT_Float64`, `GDT_CInt16`, `GDT_CInt32`, `GDT_CFloat32`, and `GDT_CFloat64`.

color_interp(as_string=False)

The color interpretation for the band, as an integer between 0 and 16. If `as_string` is `True`, the data type is returned as a string with the following possible values: `GCI_Undefined`, `GCI_GrayIndex`, `GCI_PaletteIndex`, `GCI_RedBand`, `GCI_GreenBand`, `GCI_BlueBand`, `GCI_AlphaBand`, `GCI_HueBand`, `GCI_SaturationBand`, `GCI_LightnessBand`, `GCI_CyanBand`, `GCI_MagentaBand`, `GCI_YellowBand`, `GCI_BlackBand`, `GCI_YCbCr_YBand`, `GCI_YCbCr_CbBand`, and `GCI_YCbCr_CrBand`. `GCI_YCbCr_CrBand` also represents `GCI_Max` because both correspond to the integer 16, but only `GCI_YCbCr_CrBand` is returned as a string.

data(data=None, offset=None, size=None, shape=None)

The accessor to the pixel values of the `GDALBand`. Returns the complete data array if no parameters are provided. A subset of the pixel array can be requested by specifying an offset and block size as tuples.

If NumPy is available, the data is returned as NumPy array. For performance reasons, it is highly recommended to use NumPy.

Data is written to the `GDALBand` if the `data` parameter is provided. The input can be of one of the following types - packed string, buffer, list, array, and NumPy array. The number of items in the input should normally correspond to the total number of pixels in the band, or to the number of pixels for a specific block of pixel values if the `offset` and `size` parameters are provided.

If the number of items in the input is different from the target pixel block, the `shape` parameter must be specified. The shape is a tuple that specifies the width and height of the input data in pixels. The data is then replicated to update the pixel values of the selected block. This is useful to fill an entire band with a single value, for instance.

For example:

```
>>> rst = GDALRaster({'width': 4, 'height': 4, 'srid': 4326, 'datatype': 1, 'nr_of_bands': 1})
```

(continues on next page)

(continued from previous page)

```
>>> bnd = rst.bands[0]
>>> bnd.data(range(16))
>>> bnd.data()
array([[ 0,  1,  2,  3],
       [ 4,  5,  6,  7],
       [ 8,  9, 10, 11],
       [12, 13, 14, 15]], dtype=int8)
>>> bnd.data(offset=(1, 1), size=(2, 2))
array([[ 5,  6],
       [ 9, 10]], dtype=int8)
>>> bnd.data(data=[-1, -2, -3, -4], offset=(1, 1), size=(2, 2))
>>> bnd.data()
array([[ 0,  1,  2,  3],
       [ 4, -1, -2,  7],
       [ 8, -3, -4, 11],
       [12, 13, 14, 15]], dtype=int8)
>>> bnd.data(data='\x9d\xa8\xb3\xbe', offset=(1, 1), size=(2, 2))
>>> bnd.data()
array([[ 0,  1,  2,  3],
       [ 4, -99, -88,  7],
       [ 8, -77, -66, 11],
       [12, 13, 14, 15]], dtype=int8)
>>> bnd.data([1], shape=(1, 1))
>>> bnd.data()
array([[1, 1, 1, 1],
       [1, 1, 1, 1],
       [1, 1, 1, 1],
       [1, 1, 1, 1]], dtype=uint8)
>>> bnd.data(range(4), shape=(1, 4))
array([[0, 0, 0, 0],
       [1, 1, 1, 1],
       [2, 2, 2, 2],
       [3, 3, 3, 3]], dtype=uint8)
```

metadata

The metadata of this band. The functionality is identical to *GDALRaster.metadata*.

Creating rasters from data

This section describes how to create rasters from scratch using the `ds_input` parameter.

A new raster is created when a `dict` is passed to the `GDALRaster` constructor. The dictionary contains defining parameters of the new raster, such as the origin, size, or spatial reference system. The dictionary can also contain pixel data and information about the format of the new raster. The resulting raster can therefore be file-based or memory-based, depending on the driver specified.

There's no standard for describing raster data in a dictionary or JSON flavor. The definition of the dictionary input to the `GDALRaster` class is therefore specific to Django. It's inspired by the `geojson` format, but the `geojson` standard is currently limited to vector formats.

Examples of using the different keys when creating rasters can be found in the documentation of the corresponding attributes and methods of the `GDALRaster` and `GDALBand` classes.

The `ds_input` dictionary

Only a few keys are required in the `ds_input` dictionary to create a raster: `width`, `height`, and `srid`. All other parameters have default values (see the table below). The list of keys that can be passed in the `ds_input` dictionary is closely related but not identical to the `GDALRaster` properties. Many of the parameters are mapped directly to those properties; the others are described below.

The following table describes all keys that can be set in the `ds_input` dictionary.

Key	Default	Usage
<code>srid</code>	required	Mapped to the <code>srid</code> attribute
<code>width</code>	required	Mapped to the <code>width</code> attribute
<code>height</code>	required	Mapped to the <code>height</code> attribute
<code>driver</code>	MEM	Mapped to the <code>driver</code> attribute
<code>name</code>	' '	See below
<code>origin</code>	0	Mapped to the <code>origin</code> attribute
<code>scale</code>	0	Mapped to the <code>scale</code> attribute
<code>skew</code>	0	Mapped to the <code>width</code> attribute
<code>bands</code>	[]	See below
<code>nr_of_bands</code>	0	See below
<code>datatype</code>	6	See below
<code>papsz_options</code>	{}	See below

`name`

String representing the name of the raster. When creating a file-based raster, this parameter must be the file path for the new raster. If the name starts with `/vsimem/`, the raster is created in GDAL's virtual filesystem.

datatype

Integer representing the data type for all the bands. Defaults to 6 (Float32). All bands of a new raster are required to have the same datatype. The value mapping is:

Value	GDAL Pixel Type	Description
1	GDT_Byte	Eight bit unsigned integer
2	GDT_UInt16	Sixteen bit unsigned integer
3	GDT_Int16	Sixteen bit signed integer
4	GDT_UInt32	Thirty-two bit unsigned integer
5	GDT_Int32	Thirty-two bit signed integer
6	GDT_Float32	Thirty-two bit floating point
7	GDT_Float64	Sixty-four bit floating point

nr_of_bands

Integer representing the number of bands of the raster. A raster can be created without passing band data upon creation. If the number of bands isn't specified, it's automatically calculated from the length of the `bands` input. The number of bands can't be changed after creation.

bands

A list of `band_input` dictionaries with band input data. The resulting band indices are the same as in the list provided. The definition of the band input dictionary is given below. If band data isn't provided, the raster bands values are instantiated as an array of zeros and the "no data" value is set to `None`.

papsz_options

A dictionary with raster creation options. The key-value pairs of the input dictionary are passed to the driver on creation of the raster.

The available options are driver-specific and are described in the documentation of each driver.

The values in the dictionary are not case-sensitive and are automatically converted to the correct string format upon creation.

The following example uses some of the options available for the [GTiff driver](#). The result is a compressed signed byte raster with an internal tiling scheme. The internal tiles have a block size of 23 by 23:

```
>>> GDALRaster(  
...     {  
...         "driver": "GTiff",  
...         "name": "/path/to/new/file.tif",  
...         "srid": 4326,  
...         "width": 255,  
...         "height": 255,  
...     }
```

(continues on next page)

(continued from previous page)

```

...     "nr_of_bands": 1,
...     "papsz_options": {
...         "compress": "packbits",
...         "pixeltype": "signedbyte",
...         "tiled": "yes",
...         "blockxsize": 23,
...         "blockysize": 23,
...     },
... }
... )

```

The `band_input` dictionary

The `bands` key in the `ds_input` dictionary is a list of `band_input` dictionaries. Each `band_input` dictionary can contain pixel values and the “no data” value to be set on the bands of the new raster. The data array can have the full size of the new raster or be smaller. For arrays that are smaller than the full raster, the `size`, `shape`, and `offset` keys control the pixel values. The corresponding keys are passed to the `data()` method. Their functionality is the same as setting the band data with that method. The following table describes the keys that can be used.

Key	Default	Usage
<code>nodata_value</code>	<code>None</code>	Mapped to the <code>nodata_value</code> attribute
<code>data</code>	Same as <code>nodata_value</code> or 0	Passed to the <code>data()</code> method
<code>size</code>	(width, height) of raster	Passed to the <code>data()</code> method
<code>shape</code>	Same as <code>size</code>	Passed to the <code>data()</code> method
<code>offset</code>	(0, 0)	Passed to the <code>data()</code> method

Using GDAL’s Virtual Filesystem

GDAL can access files stored in the filesystem, but also supports virtual filesystems to abstract accessing other kind of files, such as compressed, encrypted, or remote files.

Using memory-based Virtual Filesystem

GDAL has an internal memory-based filesystem, which allows treating blocks of memory as files. It can be used to read and write *GDALRaster* objects to and from binary file buffers.

This is useful in web contexts where rasters might be obtained as a buffer from a remote storage or returned from a view without being written to disk.

GDALRaster objects are created in the virtual filesystem when a `bytes` object is provided as input, or when the file path starts with `/vsimem/`.

Input provided as `bytes` has to be a full binary representation of a file. For instance:

```
# Read a raster as a file object from a remote source.
>>> from urllib.request import urlopen
>>> dat = urlopen("http://example.com/raster.tif").read()
# Instantiate a raster from the bytes object.
>>> rst = GDALRaster(dat)
# The name starts with /vsimem/, indicating that the raster lives in the
# virtual filesystem.
>>> rst.name
'/vsimem/da300bdb-129d-49a8-b336-e410a9428dad'
```

To create a new virtual file-based raster from scratch, use the `ds_input` dictionary representation and provide a `name` argument that starts with `/vsimem/` (for detail of the dictionary representation, see [Creating rasters from data](#)). For virtual file-based rasters, the *vsi_buffer* attribute returns the `bytes` representation of the raster.

Here's how to create a raster and return it as a file in an *HttpResponse*:

```
>>> from django.http import HttpResponse
>>> rst = GDALRaster(
...     {
...         "name": "/vsimem/temporarymemfile",
...         "driver": "tif",
...         "width": 6,
...         "height": 6,
...         "srid": 3086,
...         "origin": [500000, 400000],
...         "scale": [100, -100],
...         "bands": [{"data": range(36), "nodata_value": 99}],
...     }
... )
>>> HttpResponse(rst.vsi_buffer, "image/tiff")
```

Using other Virtual Filesystems

Depending on the local build of GDAL other virtual filesystems may be supported. You can use them by prepending the provided path with the appropriate `/vsi*/` prefix. See the [GDAL Virtual Filesystems documentation](#) for more details.

Compressed rasters

Instead decompressing the file and instantiating the resulting raster, GDAL can directly access compressed files using the `/vsizip/`, `/vsigzip/`, or `/vsitar/` virtual filesystems:

```
>>> from django.contrib.gis.gdal import GDALRaster
>>> rst = GDALRaster("/vsizip/path/to/your/file.zip/path/to/raster.tif")
>>> rst = GDALRaster("/vsigzip/path/to/your/file.gz")
>>> rst = GDALRaster("/vsitar/path/to/your/file.tar/path/to/raster.tif")
```

Network rasters

GDAL can support online resources and storage providers transparently. As long as it's built with such capabilities.

To access a public raster file with no authentication, you can use `/vsicurl/`:

```
>>> from django.contrib.gis.gdal import GDALRaster
>>> rst = GDALRaster("/vsicurl/https://example.com/raster.tif")
>>> rst.name
'/vsicurl/https://example.com/raster.tif'
```

For commercial storage providers (e.g. `/vsis3/`) the system should be previously configured for authentication and possibly other settings (see the [GDAL Virtual Filesystems documentation](#) for available options).

Settings

GDAL_LIBRARY_PATH

A string specifying the location of the GDAL library. Typically, this setting is only used if the GDAL library is in a non-standard location (e.g., `/home/john/lib/libgdal.so`).

Exceptions

`exception GDALException`

The base GDAL exception, indicating a GDAL-related error.

`exception SRSException`

An exception raised when an error occurs when constructing or using a spatial reference system object.

Geolocation with GeoIP2

The *GeoIP2* object is a wrapper for the [MaxMind geoip2 Python library](#).¹

In order to perform IP-based geolocation, the *GeoIP2* object requires the *geoip2* Python package and the GeoIP Country and/or City datasets in binary format (the CSV files will not work!), downloaded from e.g. [MaxMind](#) or [DB-IP](#) websites. Grab the *GeoLite2-Country.mmdb.gz* and *GeoLite2-City.mmdb.gz* files and unzip them in a directory corresponding to the *GEOIP_PATH* setting.

Additionally, it is recommended to install the *libmaxminddb* C library, so that *geoip2* can leverage the C library's faster speed.

Support for *.mmdb* files downloaded from DB-IP was added.

Example

Here is an example of its usage:

```
>>> from django.contrib.gis.geoip2 import GeoIP2
>>> g = GeoIP2()
>>> g.country("google.com")
{'country_code': 'US', 'country_name': 'United States'}
>>> g.city("72.14.207.99")
{'city': 'Mountain View',
 'continent_code': 'NA',
 'continent_name': 'North America',
 'country_code': 'US',
 'country_name': 'United States',
 'dma_code': 807,
 'is_in_european_union': False,
 'latitude': 37.419200897216797,
 'longitude': -122.05740356445312,
 'postal_code': '94043',
 'region': 'CA',
 'time_zone': 'America/Los_Angeles'}
```

(continues on next page)

¹ GeoIP(R) is a registered trademark of MaxMind, Inc.

(continued from previous page)

```
>>> g.lat_lon("salon.com")
(39.0437, -77.4875)
>>> g.lon_lat("uh.edu")
(-95.4342, 29.834)
>>> g.geos("24.124.1.80").wkt
'POINT (-97 38)'
```

API Reference

class `GeoIP2`(path=None, cache=0, country=None, city=None)

The `GeoIP` object does not require any parameters to use the default settings. However, at the very least the `GEOIP_PATH` setting should be set with the path of the location of your GeoIP datasets. The following initialization keywords may be used to customize any of the defaults.

Key-word Arguments	Description
<code>path</code>	Base directory to where GeoIP data is located or the full path to where the city or country data files (<code>.mmdb</code>) are located. Assumes that both the city and country datasets are located in this directory; overrides the <code>GEOIP_PATH</code> setting.
<code>cache</code>	The cache settings when opening up the GeoIP datasets. May be an integer in (0, 1, 2, 4, 8) corresponding to the <code>MODE_AUTO</code> , <code>MODE_MMAP_EXT</code> , <code>MODE_MMAP</code> , and <code>GEOIP_INDEX_CACHE</code> <code>MODE_MEMORY</code> C API settings, respectively. Defaults to 0 (<code>MODE_AUTO</code>).
<code>country</code>	The name of the GeoIP country data file. Defaults to <code>GeoLite2-Country.mmdb</code> . Setting this keyword overrides the <code>GEOIP_COUNTRY</code> setting.
<code>city</code>	The name of the GeoIP city data file. Defaults to <code>GeoLite2-City.mmdb</code> . Setting this keyword overrides the <code>GEOIP_CITY</code> setting.

Methods

Instantiating

classmethod `GeoIP2.open`(path, cache)

This classmethod instantiates the `GeoIP` object from the given database path and given cache setting.

Querying

All the following querying routines may take either a string IP address or a fully qualified domain name (FQDN). For example, both '205.186.163.125' and 'djangoproject.com' would be valid query parameters.

`GeoIP2.city(query)`

Returns a dictionary of city information for the given query. Some of the values in the dictionary may be undefined (`None`).

`GeoIP2.country(query)`

Returns a dictionary with the country code and country for the given query.

`GeoIP2.country_code(query)`

Returns the country code corresponding to the query.

`GeoIP2.country_name(query)`

Returns the country name corresponding to the query.

Coordinate Retrieval

`GeoIP2.coords(query)`

Returns a coordinate tuple of (longitude, latitude).

`GeoIP2.lon_lat(query)`

Returns a coordinate tuple of (longitude, latitude).

`GeoIP2.lat_lon(query)`

Returns a coordinate tuple of (latitude, longitude),

`GeoIP2.geos(query)`

Returns a *Point* object corresponding to the query.

Settings

`GEOIP_PATH`

A string or `pathlib.Path` specifying the directory where the GeoIP data files are located. This setting is required unless manually specified with `path` keyword when initializing the *GeoIP2* object.

GEOIP_COUNTRY

The basename to use for the GeoIP country data file. Defaults to 'GeoLite2-Country.mmdb'.

GEOIP_CITY

The basename to use for the GeoIP city data file. Defaults to 'GeoLite2-City.mmdb'.

Exceptions

exception `GeoIP2Exception`

The exception raised when an error occurs in a call to the underlying `geoip2` library.

GeoDjango Utilities

The `django.contrib.gis.utils` module contains various utilities that are useful in creating geospatial web applications.

LayerMapping data import utility

The `LayerMapping` class provides a way to map the contents of vector spatial data files (e.g. shapefiles) into GeoDjango models.

This utility grew out of the author's personal needs to eliminate the code repetition that went into pulling geometries and fields out of a vector layer, converting to another coordinate system (e.g. WGS84), and then inserting into a GeoDjango model.

Note: Use of `LayerMapping` requires GDAL.

Warning: GIS data sources, like shapefiles, may be very large. If you find that `LayerMapping` is using too much memory, set `DEBUG` to `False` in your settings. When `DEBUG` is set to `True`, Django automatically logs every SQL query –and when SQL statements contain geometries, this may consume more memory than is typical.

Example

1. You need a GDAL-supported data source, like a shapefile (here we're using a simple polygon shapefile, `test_poly.shp`, with three features):

```
>>> from django.contrib.gis.gdal import DataSource
>>> ds = DataSource("test_poly.shp")
>>> layer = ds[0]
>>> print(layer.fields) # Exploring the fields in the layer, we only want the 'str' field.
['float', 'int', 'str']
>>> print(len(layer)) # getting the number of features in the layer (should be 3)
3
>>> print(layer.geom_type) # Should be 'Polygon'
Polygon
>>> print(layer.srs) # WGS84 in WKT
GEOGCS["GCS_WGS_1984",
    DATUM["WGS_1984",
        SPHEROID["WGS_1984",6378137,298.257223563]],
    PRIMEM["Greenwich",0],
    UNIT["Degree",0.017453292519943295]]
```

1. Now we define our corresponding Django model (make sure to use *migrate*):

```
from django.contrib.gis.db import models

class TestGeo(models.Model):
    name = models.CharField(max_length=25) # corresponds to the 'str' field
    poly = models.PolygonField(srid=4269) # we want our model in a different SRID

    def __str__(self):
        return "Name: %s" % self.name
```

2. Use *LayerMapping* to extract all the features and place them in the database:

```
>>> from django.contrib.gis.utils import LayerMapping
>>> from geoapp.models import TestGeo
>>> mapping = {
...     "name": "str", # The 'name' model field maps to the 'str' layer field.
...     "poly": "POLYGON", # For geometry fields use OGC name.
... } # The mapping is a dictionary
>>> lm = LayerMapping(TestGeo, "test_poly.shp", mapping)
>>> lm.save(verbose=True) # Save the layermap, imports the data.
Saved: Name: 1
Saved: Name: 2
```

(continues on next page)

(continued from previous page)

Saved: Name: 3

Here, *LayerMapping* transformed the three geometries from the shapefile in their original spatial reference system (WGS84) to the spatial reference system of the GeoDjango model (NAD83). If no spatial reference system is defined for the layer, use the `source_srs` keyword with a *SpatialReference* object to specify one.

LayerMapping API

```
class LayerMapping(model, data_source, mapping, layer=0, source_srs=None, encoding=None,
                    transaction_mode='commit_on_success', transform=True, unique=True,
                    using='default')
```

The following are the arguments and keywords that may be used during instantiation of *LayerMapping* objects.

Ar- gu- ment	Description
<code>model</code>	The geographic model, not an instance.
<code>data_</code>	The path to the OGR-supported data source file (e.g., a shapefile). Also accepts <i>django.contrib.gis.gdal.DataSource</i> instances.
<code>mappi</code>	A dictionary: keys are strings corresponding to the model field, and values correspond to string field names for the OGR feature, or if the model field is a geographic then it should correspond to the OGR geometry type, e.g., 'POINT', 'LINESTRING', 'POLYGON'.

Key-word	Arguments
<code>layer</code>	The index of the layer to use from the Data Source (defaults to 0)
<code>source_</code>	Use this to specify the source SRS manually (for example, some shapefiles don't come with a '.prj' file). An integer SRID, WKT or PROJ strings, and django.contrib.gis.gdal.SpatialReference objects are accepted.
<code>encodin</code>	Specifies the character set encoding of the strings in the OGR data source. For example, 'latin-1', 'utf-8', and 'cp437' are all valid encoding parameters.
<code>transac</code>	May be 'commit_on_success' (default) or 'autocommit'.
<code>transfo</code>	Setting this to False will disable coordinate transformations. In other words, geometries will be inserted into the database unmodified from their original state in the data source.
<code>unique</code>	Setting this to the name, or a tuple of names, from the given model will create models unique only to the given name(s). Geometries from each feature will be added into the collection associated with the unique model. Forces the transaction mode to be 'autocommit'.
<code>using</code>	Sets the database to use when importing spatial data. Default is 'default'.

`save()` Keyword Arguments

`LayerMapping.save(verbose=False, fid_range=False, step=False, progress=False, silent=False, stream=sys.stdout, strict=False)`

The `save()` method also accepts keywords. These keywords are used for controlling output logging, error handling, and for importing specific feature ranges.

Save Key- word Argu- ments	Description
<code>fid_range</code>	May be set with a slice or tuple of (begin, end) feature ID's to map from the data source. In other words, this keyword enables the user to selectively import a subset range of features in the geographic data source.
<code>progress</code>	When this keyword is set, status information will be printed giving the number of features processed and successfully saved. By default, progress information will be printed every 1000 features processed, however, this default may be overridden by setting this keyword with an integer for the desired interval.
<code>silent</code>	By default, non-fatal error notifications are printed to <code>sys.stdout</code> , but this keyword may be set to disable these notifications.
<code>step</code>	If set with an integer, transactions will occur at every step interval. For example, if <code>step=1000</code> , a commit would occur after the 1,000th feature, the 2,000th feature etc.
<code>stream</code>	Status information will be written to this file handle. Defaults to using <code>sys.stdout</code> , but any object with a <code>write</code> method is supported.
<code>strict</code>	Execution of the model mapping will cease upon the first error encountered. The default value (<code>False</code>) behavior is to attempt to continue.
<code>verbose</code>	If set, information will be printed subsequent to each model save executed on the database.

Troubleshooting

Running out of memory

As noted in the warning at the top of this section, Django stores all SQL queries when `DEBUG=True`. Set `DEBUG=False` in your settings, and this should stop excessive memory use when running LayerMapping scripts.

MySQL: `max_allowed_packet` error

If you encounter the following error when using LayerMapping and MySQL:

```
OperationalError: (1153, "Got a packet bigger than 'max_allowed_packet' bytes")
```

Then the solution is to increase the value of the `max_allowed_packet` setting in your MySQL configuration. For example, the default value may be something low like one megabyte –the setting may be modified in MySQL's configuration file (`my.cnf`) in the `[mysqld]` section:

```
max_allowed_packet = 10M
```

OGR Inspection

`ogrinspect`

```
ogrinspect(data_source, model_name, **kwargs)
```

`mapping`

```
mapping(data_source, geom_name='geom', layer_key=0, multi_geom=False)
```

GeoJSON Serializer

GeoDjango provides a specific serializer for the [GeoJSON](#) format. See [Serializing Django objects](#) for more information on serialization.

The `geojson` serializer is not meant for round-tripping data, as it has no deserializer equivalent. For example, you cannot use `loaddata` to reload the output produced by this serializer. If you plan to reload the outputted data, use the plain [json serializer](#) instead.

In addition to the options of the `json` serializer, the `geojson` serializer accepts the following additional option when it is called by `serializers.serialize()`:

- **geometry_field**: A string containing the name of a geometry field to use for the `geometry` key of the GeoJSON feature. This is only needed when you have a model with more than one geometry field and you don't want to use the first defined geometry field (by default, the first geometry field is picked).
- **id_field**: A string containing the name of a field to use for the `id` key of the GeoJSON feature. By default, the primary key of objects is used.
- **srid**: The SRID to use for the `geometry` content. Defaults to 4326 (WGS 84).

The [fields](#) option can be used to limit fields that will be present in the `properties` key, as it works with all other serializers.

Example:

```
from django.core.serializers import serialize
from my_app.models import City

serialize("geojson", City.objects.all(), geometry_field="point", fields=["name"])
```

Would output:

```
{
  "type": "FeatureCollection",
  "crs": {"type": "name", "properties": {"name": "EPSG:4326"}},
  "features": [
    {
      "type": "Feature",
      "id": 1,
      "geometry": {"type": "Point", "coordinates": [-87.650175, 41.850385]},
      "properties": {"name": "Chicago"},
    }
  ],
}
```

When the `fields` parameter is not specified, the `geojson` serializer adds a `pk` key to the `properties` dictionary with the primary key of the object as the value.

The `id` key for serialized features was added. Also, the `id_field` option was added to the `geojson` serializer.

GeoDjango Management Commands

`inspectdb`

`django-admin inspectdb`

When `django.contrib.gis` is in your `INSTALLED_APPS`, the `inspectdb` management command is overridden with one from GeoDjango. The overridden command is spatially-aware, and places geometry fields in the auto-generated model definition, where appropriate.

`ogrinspect`

`django-admin ogrinspect data_source model_name`

The `ogrinspect` management command will inspect the given OGR-compatible *DataSource* (e.g., a shapefile) and will output a GeoDjango model with the given model name. There's a detailed example of using `ogrinspect` in the tutorial.

`--blank BLANK`

Use a comma separated list of OGR field names to add the `blank=True` keyword option to the field definition. Set with `true` to apply to all applicable fields.

`--decimal DECIMAL`

Use a comma separated list of OGR float fields to generate *DecimalField* instead of the default *FloatField*. Set to `true` to apply to all OGR float fields.

--geom-name GEOM_NAME

Specifies the model attribute name to use for the geometry field. Defaults to 'geom'.

--layer LAYER_KEY

The key for specifying which layer in the OGR *DataSource* source to use. Defaults to 0 (the first layer). May be an integer or a string identifier for the *Layer*. When inspecting databases, *layer* is generally the table name you want to inspect.

--mapping

Automatically generate a mapping dictionary for use with *LayerMapping*.

--multi-geom

When generating the geometry field, treat it as a geometry collection. For example, if this setting is enabled then a *MultiPolygonField* will be placed in the generated model rather than *PolygonField*.

--name-field NAME_FIELD

Generates a `__str__()` method on the model that returns the given field name.

--no-imports

Suppresses the `from django.contrib.gis.db import models` import statement.

--null NULL

Use a comma separated list of OGR field names to add the `null=True` keyword option to the field definition. Set with `true` to apply to all applicable fields.

--srid SRID

The SRID to use for the geometry field. If not set, *ogrinspect* attempts to automatically determine of the SRID of the data source.

GeoDjango's admin site

GISModelAdmin

`class GISModelAdmin`

`gis_widget`

The widget class to be used for *GeometryField*. Defaults to *OSMWidget*.

`gis_widget_kwargs`

The keyword arguments that would be passed to the *gis_widget*. Defaults to an empty dictionary.

GeoModelAdmin

`class GeoModelAdmin`

`default_lon`

The default center longitude.

`default_lat`

The default center latitude.

`default_zoom`

The default zoom level to use. Defaults to 4.

`extra_js`

Sequence of URLs to any extra JavaScript to include.

`map_template`

Override the template used to generate the JavaScript slippy map. Default is 'gis/admin/openlayers.html'.

`map_width`

Width of the map, in pixels. Defaults to 600.

`map_height`

Height of the map, in pixels. Defaults to 400.

`openlayers_url`

Link to the URL of the OpenLayers JavaScript. Defaults to 'https://cdnjs.cloudflare.com/ajax/libs/openlayers/2.13.1/OpenLayers.js'.

`modifiable`

Defaults to True. When set to False, disables editing of existing geometry fields in the admin.

Note: This is different from adding the geometry field to *readonly_fields*, which will only display the WKT of the geometry. Setting `modifiable=False`, actually displays the geometry in a map, but disables the ability to edit its vertices.

Deprecated since version 4.0: This class is deprecated. Use *ModelAdmin* instead.

OSMGeoAdmin

class OSMGeoAdmin

A subclass of *GeoModelAdmin* that uses a Spherical Mercator projection with [OpenStreetMap](#) street data tiles.

Deprecated since version 4.0: This class is deprecated. Use *GISModelAdmin* instead.

Geographic Feeds

GeoDjango has its own *Feed* subclass that may embed location information in RSS/Atom feeds formatted according to either the [Simple GeoRSS](#) or [W3C Geo](#) standards. Because GeoDjango's syndication API is a superset of Django's, please consult [Django's syndication documentation](#) for details on general usage.

Example

API Reference

Feed Subclass

class Feed

In addition to methods provided by the *django.contrib.syndication.views.Feed* base class, GeoDjango's *Feed* class provides the following overrides. Note that these overrides may be done in multiple ways:

```
from django.contrib.gis.feeds import Feed

class MyFeed(Feed):
    # First, as a class attribute.
    geometry = ...
    item_geometry = ...

    # Also a function with no arguments
    def geometry(self):
        ...

    def item_geometry(self):
        ...

    # And as a function with a single argument
    def geometry(self, obj):
```

(continues on next page)

(continued from previous page)

```
...

def item_geometry(self, item):
    ...
```

`geometry(obj)`

Takes the object returned by `get_object()` and returns the feed's geometry. Typically this is a `GEOSGeometry` instance, or can be a tuple to represent a point or a box. For example:

```
class ZipcodeFeed(Feed):
    def geometry(self, obj):
        # Can also return: `obj.poly`, and `obj.poly.centroid`.
        return obj.poly.extent # tuple like: (X0, Y0, X1, Y1).
```

`item_geometry(item)`

Set this to return the geometry for each item in the feed. This can be a `GEOSGeometry` instance, or a tuple that represents a point coordinate or bounding box. For example:

```
class ZipcodeFeed(Feed):
    def item_geometry(self, obj):
        # Returns the polygon.
        return obj.poly
```

SyndicationFeed Subclasses

The following `django.utils.feedgenerator.SyndicationFeed` subclasses are available:

```
class GeoRSSFeed
```

```
class GeoAtom1Feed
```

```
class W3CGeoFeed
```

Note: `W3C Geo` formatted feeds only support `PointField` geometries.

Geographic Sitemaps

KML is an XML language focused on geographic visualization¹. `KMLitemap` and its compressed counterpart `KMZitemap` allow you to present geolocated data in a machine-readable format.

Example

Reference

`KMLitemap`

`KMZitemap`

Testing GeoDjango apps

Included in this documentation are some additional notes and settings for `PostGIS` users.

PostGIS

Settings

Note: The settings below have sensible defaults, and shouldn't require manual setting.

`POSTGIS_VERSION`

When GeoDjango's spatial backend initializes on PostGIS, it has to perform an SQL query to determine the version in order to figure out what features are available. Advanced users wishing to prevent this additional query may set the version manually using a 3-tuple of integers specifying the major, minor, and micro version numbers for PostGIS. For example, to configure for PostGIS X.Y.Z you would use:

```
POSTGIS_VERSION = (X, Y, Z)
```

¹ <https://www.ogc.org/standards/kml>

Obtaining sufficient privileges

Depending on your configuration, this section describes several methods to configure a database user with sufficient privileges to run tests for GeoDjango applications on PostgreSQL. If your [spatial database template](#) was created like in the instructions, then your testing database user only needs to have the ability to create databases. In other configurations, you may be required to use a database superuser.

Create database user

To make a database user with the ability to create databases, use the following command:

```
$ createuser --createdb -R -S <user_name>
```

The `-R` `-S` flags indicate that we do not want the user to have the ability to create additional users (roles) or to be a superuser, respectively.

Alternatively, you may alter an existing user's role from the SQL shell (assuming this is done from an existing superuser account):

```
postgres# ALTER ROLE <user_name> CREATEDB NOSUPERUSER NOCREATEROLE;
```

Create database superuser

This may be done at the time the user is created, for example:

```
$ createuser --superuser <user_name>
```

Or you may alter the user's role from the SQL shell (assuming this is done from an existing superuser account):

```
postgres# ALTER ROLE <user_name> SUPERUSER;
```

Windows

On Windows platforms you can use the pgAdmin III utility to add superuser privileges to your database user.

By default, the PostGIS installer on Windows includes a template spatial database entitled `template_postgis`.

GeoDjango tests

To have the GeoDjango tests executed when [running the Django test suite](#) with `runtests.py` all of the databases in the settings file must be using one of the [spatial database backends](#).

Example

The following is an example bare-bones settings file with spatial backends that can be used to run the entire Django test suite, including those in *django.contrib.gis*:

```
DATABASES = {
    "default": {
        "ENGINE": "django.contrib.gis.db.backends.postgis",
        "NAME": "geodjango",
        "USER": "geodjango",
    },
    "other": {
        "ENGINE": "django.contrib.gis.db.backends.postgis",
        "NAME": "other",
        "USER": "geodjango",
    },
}

SECRET_KEY = "django_tests_secret_key"
```

Assuming the settings above were in a `postgis.py` file in the same directory as `runtests.py`, then all Django and GeoDjango tests would be performed when executing the command:

```
$ ./runtests.py --settings=postgis
```

To run only the GeoDjango test suite, specify `gis_tests`:

```
$ ./runtests.py --settings=postgis gis_tests
```

Deploying GeoDjango

Basically, the deployment of a GeoDjango application is not different from the deployment of a normal Django application. Please consult Django's [deployment documentation](#).

Warning: GeoDjango uses the GDAL geospatial library which is not thread safe at this time. Thus, it is highly recommended to not use threading when deploying –in other words, use an appropriate configuration of Apache.

For example, when configuring your application with `mod_wsgi`, set the `WSGIDaemonProcess` attribute `threads` to 1, unless Apache may crash when running your GeoDjango application. Increase the number of processes instead.

6.5.6 `django.contrib.humanize`

A set of Django template filters useful for adding a “human touch” to data.

To activate these filters, add `'django.contrib.humanize'` to your `INSTALLED_APPS` setting. Once you’ve done that, use `{% load humanize %}` in a template, and you’ll have access to the following filters.

`apnumber`

For numbers 1-9, returns the number spelled out. Otherwise, returns the number. This follows Associated Press style.

Examples:

- 1 becomes one.
- 2 becomes two.
- 10 becomes 10.

You can pass in either an integer or a string representation of an integer.

`intcomma`

Converts an integer or float (or a string representation of either) to a string containing commas every three digits.

Examples:

- 4500 becomes 4,500.
- 4500.2 becomes 4,500.2.
- 45000 becomes 45,000.
- 450000 becomes 450,000.
- 4500000 becomes 4,500,000.

`Format localization` will be respected if enabled, e.g. with the `'de'` language:

- 45000 becomes `'45.000'`.
- 450000 becomes `'450.000'`.

`intword`

Converts a large integer (or a string representation of an integer) to a friendly text representation. Translates 1.0 as a singular phrase and all other numeric values as plural, this may be incorrect for some languages. Works best for numbers over 1 million.

Examples:

- 1000000 becomes 1.0 million.
- 1200000 becomes 1.2 million.
- 1200000000 becomes 1.2 billion.
- -1200000000 becomes -1.2 billion.

Values up to 10^{100} (Googol) are supported.

Format `localization` will be respected if enabled, e.g. with the 'de' language:

- 1000000 becomes '1,0 Million'.
- 1200000 becomes '1,2 Millionen'.
- 1200000000 becomes '1,2 Milliarden'.
- -1200000000 becomes '-1,2 Milliarden'.

`naturalday`

For dates that are the current day or within one day, return “today” , “tomorrow” or “yesterday” , as appropriate. Otherwise, format the date using the passed in format string.

Argument: Date formatting string as described in the `date` tag.

Examples (when ‘today’ is 17 Feb 2007):

- 16 Feb 2007 becomes yesterday.
- 17 Feb 2007 becomes today.
- 18 Feb 2007 becomes tomorrow.
- Any other day is formatted according to given argument or the `DATE_FORMAT` setting if no argument is given.

`naturaltime`

For datetime values, returns a string representing how many seconds, minutes or hours ago it was –falling back to the *timesince* format if the value is more than a day old. In case the datetime value is in the future the return value will automatically use an appropriate phrase.

Examples (when ‘now’ is 17 Feb 2007 16:30:00):

- 17 Feb 2007 16:30:00 becomes now.
- 17 Feb 2007 16:29:31 becomes 29 seconds ago.
- 17 Feb 2007 16:29:00 becomes a minute ago.
- 17 Feb 2007 16:25:35 becomes 4 minutes ago.
- 17 Feb 2007 15:30:29 becomes 59 minutes ago.
- 17 Feb 2007 15:30:01 becomes 59 minutes ago.
- 17 Feb 2007 15:30:00 becomes an hour ago.
- 17 Feb 2007 13:31:29 becomes 2 hours ago.
- 16 Feb 2007 13:31:29 becomes 1 day, 2 hours ago.
- 16 Feb 2007 13:30:01 becomes 1 day, 2 hours ago.
- 16 Feb 2007 13:30:00 becomes 1 day, 3 hours ago.
- 17 Feb 2007 16:30:30 becomes 30 seconds from now.
- 17 Feb 2007 16:30:29 becomes 29 seconds from now.
- 17 Feb 2007 16:31:00 becomes a minute from now.
- 17 Feb 2007 16:34:35 becomes 4 minutes from now.
- 17 Feb 2007 17:30:29 becomes an hour from now.
- 17 Feb 2007 18:31:29 becomes 2 hours from now.
- 18 Feb 2007 16:31:29 becomes 1 day from now.
- 26 Feb 2007 18:31:29 becomes 1 week, 2 days from now.

`ordinal`

Converts an integer to its ordinal as a string.

Examples:

- 1 becomes 1st.
- 2 becomes 2nd.

- 3 becomes 3rd.

You can pass in either an integer or a string representation of an integer.

6.5.7 The messages framework

Quite commonly in web applications, you need to display a one-time notification message (also known as “flash message”) to the user after processing a form or some other types of user input.

For this, Django provides full support for cookie- and session-based messaging, for both anonymous and authenticated users. The messages framework allows you to temporarily store messages in one request and retrieve them for display in a subsequent request (usually the next one). Every message is tagged with a specific `level` that determines its priority (e.g., `info`, `warning`, or `error`).

Enabling messages

Messages are implemented through a [middleware](#) class and corresponding [context processor](#).

The default `settings.py` created by `django-admin startproject` already contains all the settings required to enable message functionality:

- `'django.contrib.messages'` is in [INSTALLED_APPS](#).
- [MIDDLEWARE](#) contains `'django.contrib.sessions.middleware.SessionMiddleware'` and `'django.contrib.messages.middleware.MessageMiddleware'`.

The default [storage backend](#) relies on [sessions](#). That’s why `SessionMiddleware` must be enabled and appear before `MessageMiddleware` in [MIDDLEWARE](#).

- The `'context_processors'` option of the DjangoTemplates backend defined in your [TEMPLATES](#) setting contains `'django.contrib.messages.context_processors.messages'`.

If you don’t want to use messages, you can remove `'django.contrib.messages'` from your [INSTALLED_APPS](#), the `MessageMiddleware` line from [MIDDLEWARE](#), and the `messages` context processor from [TEMPLATES](#).

Configuring the message engine

Storage backends

The messages framework can use different backends to store temporary messages.

Django provides three built-in storage classes in `django.contrib.messages`:

```
class storage.session.SessionStorage
```

This class stores all messages inside of the request’s session. Therefore it requires Django’s `contrib.sessions` application.

class storage.cookie.CookieStorage

This class stores the message data in a cookie (signed with a secret hash to prevent manipulation) to persist notifications across requests. Old messages are dropped if the cookie data size would exceed 2048 bytes.

class storage.fallback.FallbackStorage

This class first uses `CookieStorage`, and falls back to using `SessionStorage` for the messages that could not fit in a single cookie. It also requires Django's `contrib.sessions` application.

This behavior avoids writing to the session whenever possible. It should provide the best performance in the general case.

FallbackStorage is the default storage class. If it isn't suitable to your needs, you can select another storage class by setting `MESSAGE_STORAGE` to its full import path, for example:

```
MESSAGE_STORAGE = "django.contrib.messages.storage.cookie.CookieStorage"
```

class storage.base.BaseStorage

To write your own storage class, subclass the `BaseStorage` class in `django.contrib.messages.storage`. base and implement the `_get` and `_store` methods.

Message levels

The messages framework is based on a configurable level architecture similar to that of the Python logging module. Message levels allow you to group messages by type so they can be filtered or displayed differently in views and templates.

The built-in levels, which can be imported from `django.contrib.messages` directly, are:

Constant	Purpose
DEBUG	Development-related messages that will be ignored (or removed) in a production deployment
INFO	Informational messages for the user
SUCCESS	An action was successful, e.g. "Your profile was updated successfully"
WARNING	A failure did not occur but may be imminent
ERROR	An action was not successful or some other failure occurred

The `MESSAGE_LEVEL` setting can be used to change the minimum recorded level (or it can be changed per request). Attempts to add messages of a level less than this will be ignored.

Message tags

Message tags are a string representation of the message level plus any extra tags that were added directly in the view (see [Adding extra message tags](#) below for more details). Tags are stored in a string and are separated by spaces. Typically, message tags are used as CSS classes to customize message style based on message type. By default, each level has a single tag that's a lowercase version of its own constant:

Level Constant	Tag
DEBUG	debug
INFO	info
SUCCESS	success
WARNING	warning
ERROR	error

To change the default tags for a message level (either built-in or custom), set the `MESSAGE_TAGS` setting to a dictionary containing the levels you wish to change. As this extends the default tags, you only need to provide tags for the levels you wish to override:

```
from django.contrib.messages import constants as messages

MESSAGE_TAGS = {
    messages.INFO: "",
    50: "critical",
}
```

Using messages in views and templates

`add_message(request, level, message, extra_tags='', fail_silently=False)`

Adding a message

To add a message, call:

```
from django.contrib import messages

messages.add_message(request, messages.INFO, "Hello world.")
```

Some shortcut methods provide a standard way to add messages with commonly used tags (which are usually represented as HTML classes for the message):

```
messages.debug(request, "%s SQL statements were executed." % count)
messages.info(request, "Three credits remain in your account.")
messages.success(request, "Profile details updated.")
messages.warning(request, "Your account expires in three days.")
messages.error(request, "Document deleted.")
```

Displaying messages

`get_messages(request)`

In your template, use something like:

```
{% if messages %}
<ul class="messages">
    {% for message in messages %}
    <li{% if message.tags %} class="{{ message.tags }}"{% endif %}>{{ message }}</li>
    {% endfor %}
</ul>
{% endif %}
```

If you're using the context processor, your template should be rendered with a `RequestContext`. Otherwise, ensure `messages` is available to the template context.

Even if you know there is only one message, you should still iterate over the `messages` sequence, because otherwise the message storage will not be cleared for the next request.

The context processor also provides a `DEFAULT_MESSAGE_LEVELS` variable which is a mapping of the message level names to their numeric value:

```
{% if messages %}
<ul class="messages">
    {% for message in messages %}
    <li{% if message.tags %} class="{{ message.tags }}"{% endif %}>
        {% if message.level == DEFAULT_MESSAGE_LEVELS.ERROR %}Important: {% endif %}
        {{ message }}
    </li>
    {% endfor %}
</ul>
{% endif %}
```

Outside of templates, you can use `get_messages()`:

```
from django.contrib.messages import get_messages
```

(continues on next page)

(continued from previous page)

```
storage = get_messages(request)
for message in storage:
    do_something_with_the_message(message)
```

For instance, you can fetch all the messages to return them in a [JSONResponseMixin](#) instead of a [TemplateResponseMixin](#).

`get_messages()` will return an instance of the configured storage backend.

The Message class

`class storage.base.Message`

When you loop over the list of messages in a template, what you get are instances of the `Message` class. They have only a few attributes:

- `message`: The actual text of the message.
- `level`: An integer describing the type of the message (see the [message levels](#) section above).
- `tags`: A string combining all the message's tags (`extra_tags` and `level_tag`) separated by spaces.
- `extra_tags`: A string containing custom tags for this message, separated by spaces. It's empty by default.
- `level_tag`: The string representation of the level. By default, it's the lowercase version of the name of the associated constant, but this can be changed if you need by using the [MESSAGE_TAGS](#) setting.

Creating custom message levels

Messages levels are nothing more than integers, so you can define your own level constants and use them to create more customized user feedback, e.g.:

```
CRITICAL = 50

def my_view(request):
    messages.add_message(request, CRITICAL, "A serious error occurred.")
```

When creating custom message levels you should be careful to avoid overloading existing levels. The values for the built-in levels are:

Level Constant	Value
DEBUG	10
INFO	20
SUCCESS	25
WARNING	30
ERROR	40

If you need to identify the custom levels in your HTML or CSS, you need to provide a mapping via the `MESSAGE_TAGS` setting.

Note: If you are creating a reusable application, it is recommended to use only the built-in [message levels](#) and not rely on any custom levels.

Changing the minimum recorded level per-request

The minimum recorded level can be set per request via the `set_level` method:

```
from django.contrib import messages

# Change the messages level to ensure the debug message is added.
messages.set_level(request, messages.DEBUG)
messages.debug(request, "Test message...")

# In another request, record only messages with a level of WARNING and higher
messages.set_level(request, messages.WARNING)
messages.success(request, "Your profile was updated.") # ignored
messages.warning(request, "Your account is about to expire.") # recorded

# Set the messages level back to default.
messages.set_level(request, None)
```

Similarly, the current effective level can be retrieved with `get_level`:

```
from django.contrib import messages

current_level = messages.get_level(request)
```

For more information on how the minimum recorded level functions, see [Message levels](#) above.

Adding extra message tags

For more direct control over message tags, you can optionally provide a string containing extra tags to any of the add methods:

```
messages.add_message(request, messages.INFO, "Over 9000!", extra_tags="dragonball")
messages.error(request, "Email box full", extra_tags="email")
```

Extra tags are added before the default tag for that level and are space separated.

Failing silently when the message framework is disabled

If you're writing a reusable app (or other piece of code) and want to include messaging functionality, but don't want to require your users to enable it if they don't want to, you may pass an additional keyword argument `fail_silently=True` to any of the `add_message` family of methods. For example:

```
messages.add_message(
    request,
    messages.SUCCESS,
    "Profile details updated.",
    fail_silently=True,
)
messages.info(request, "Hello world.", fail_silently=True)
```

Note: Setting `fail_silently=True` only hides the `MessageFailure` that would otherwise occur when the messages framework disabled and one attempts to use one of the `add_message` family of methods. It does not hide failures that may occur for other reasons.

Adding messages in class-based views

```
class views.SuccessMessageMixin
```

 Adds a success message attribute to *FormView* based classes

```
    get_success_message(cleaned_data)
```

`cleaned_data` is the cleaned data from the form which is used for string formatting

Example `views.py`:

```
from django.contrib.messages.views import SuccessMessageMixin
from django.views.generic.edit import CreateView
from myapp.models import Author
```

(continues on next page)

(continued from previous page)

```
class AuthorCreateView(SuccessMessageMixin, CreateView):
    model = Author
    success_url = "/success/"
    success_message = "%(name)s was created successfully"
```

The cleaned data from the form is available for string interpolation using the `%(field_name)s` syntax. For ModelForms, if you need access to fields from the saved object override the `get_success_message()` method.

Example views.py for ModelForms:

```
from django.contrib.messages.views import SuccessMessageMixin
from django.views.generic.edit import CreateView
from myapp.models import ComplicatedModel

class ComplicatedCreateView(SuccessMessageMixin, CreateView):
    model = ComplicatedModel
    success_url = "/success/"
    success_message = "%(calculated_field)s was created successfully"

    def get_success_message(self, cleaned_data):
        return self.success_message % dict(
            cleaned_data,
            calculated_field=self.object.calculated_field,
        )
```

Expiration of messages

The messages are marked to be cleared when the storage instance is iterated (and cleared when the response is processed).

To avoid the messages being cleared, you can set the messages storage to `False` after iterating:

```
storage = messages.get_messages(request)
for message in storage:
    do_something_with(message)
storage.used = False
```

Behavior of parallel requests

Due to the way cookies (and hence sessions) work, the behavior of any backends that make use of cookies or sessions is undefined when the same client makes multiple requests that set or get messages in parallel. For example, if a client initiates a request that creates a message in one window (or tab) and then another that fetches any uniterated messages in another window, before the first window redirects, the message may appear in the second window instead of the first window where it may be expected.

In short, when multiple simultaneous requests from the same client are involved, messages are not guaranteed to be delivered to the same window that created them nor, in some cases, at all. Note that this is typically not a problem in most applications and will become a non-issue in HTML5, where each window/tab will have its own browsing context.

Settings

A few [settings](#) give you control over message behavior:

- [*MESSAGE_LEVEL*](#)
- [*MESSAGE_STORAGE*](#)
- [*MESSAGE_TAGS*](#)

For backends that use cookies, the settings for the cookie are taken from the session cookie settings:

- [*SESSION_COOKIE_DOMAIN*](#)
- [*SESSION_COOKIE_SECURE*](#)
- [*SESSION_COOKIE_HTTPONLY*](#)

6.5.8 `django.contrib.postgres`

PostgreSQL has a number of features which are not shared by the other databases Django supports. This optional module contains model fields and form fields for a number of PostgreSQL specific data types.

Note: Django is, and will continue to be, a database-agnostic web framework. We would encourage those writing reusable applications for the Django community to write database-agnostic code where practical. However, we recognize that real world projects written using Django need not be database-agnostic. In fact, once a project reaches a given size changing the underlying data store is already a significant challenge and is likely to require changing the code base in some ways to handle differences between the data stores.

Django provides support for a number of data types which will only work with PostgreSQL. There is no fundamental reason why (for example) a `contrib.mysql` module does not exist, except that PostgreSQL has the richest feature set of the supported databases so its users have the most to gain.

PostgreSQL specific aggregation functions

These functions are available from the `django.contrib.postgres.aggregates` module. They are described in more detail in the [PostgreSQL docs](#).

Note: All functions come without default aliases, so you must explicitly provide one. For example:

```
>>> SomeModel.objects.aggregate(arr=ArrayAgg("somefield"))
{'arr': [0, 1, 2]}
```

Common aggregate options

All aggregates have the `filter` keyword argument and most also have the `default` keyword argument.

General-purpose aggregation functions

ArrayAgg

class `ArrayAgg`(expression, distinct=False, filter=None, default=None, ordering=(), **extra)

Returns a list of values, including nulls, concatenated into an array, or `default` if there are no values.

distinct

An optional boolean argument that determines if array values will be distinct. Defaults to `False`.

ordering

An optional string of a field name (with an optional `-` prefix which indicates descending order) or an expression (or a tuple or list of strings and/or expressions) that specifies the ordering of the elements in the result list.

Examples:

```
"some_field"
"-some_field"
from django.db.models import F
F("some_field").desc()
```

Deprecated since version 4.0: If there are no rows and `default` is not provided, `ArrayAgg` returns an empty list instead of `None`. This behavior is deprecated and will be removed in Django 5.0. If you need it, explicitly set `default` to `Value([])`.

BitAnd

```
class BitAnd(expression, filter=None, default=None, **extra)
```

Returns an `int` of the bitwise AND of all non-null input values, or `default` if all values are null.

BitOr

```
class BitOr(expression, filter=None, default=None, **extra)
```

Returns an `int` of the bitwise OR of all non-null input values, or `default` if all values are null.

BitXor

```
class BitXor(expression, filter=None, default=None, **extra)
```

Returns an `int` of the bitwise XOR of all non-null input values, or `default` if all values are null. It requires PostgreSQL 14+.

BoolAnd

```
class BoolAnd(expression, filter=None, default=None, **extra)
```

Returns `True`, if all input values are true, `default` if all values are null or if there are no values, otherwise `False`.

Usage example:

```
class Comment(models.Model):
    body = models.TextField()
    published = models.BooleanField()
    rank = models.IntegerField()
```

```
>>> from django.db.models import Q
>>> from django.contrib.postgres.aggregates import BoolAnd
>>> Comment.objects.aggregate(booland=BoolAnd("published"))
{'booland': False}
>>> Comment.objects.aggregate(booland=BoolAnd(Q(rank__lt=100)))
{'booland': True}
```

BoolOr

class BoolOr(expression, filter=None, default=None, **extra)

Returns True if at least one input value is true, default if all values are null or if there are no values, otherwise False.

Usage example:

```
class Comment(models.Model):
    body = models.TextField()
    published = models.BooleanField()
    rank = models.IntegerField()
```

```
>>> from django.db.models import Q
>>> from django.contrib.postgres.aggregates import BoolOr
>>> Comment.objects.aggregate(boolor=BoolOr("published"))
{'boolor': True}
>>> Comment.objects.aggregate(boolor=BoolOr(Q(rank__gt=2)))
{'boolor': False}
```

JSONBAgg

class JSONBAgg(expressions, distinct=False, filter=None, default=None, ordering=(), **extra)

Returns the input values as a JSON array, or default if there are no values. You can query the result using *key and index lookups*.

distinct

An optional boolean argument that determines if array values will be distinct. Defaults to False.

ordering

An optional string of a field name (with an optional "-" prefix which indicates descending order) or an expression (or a tuple or list of strings and/or expressions) that specifies the ordering of the elements in the result list.

Examples are the same as for *ArrayAgg.ordering*.

Usage example:

```
class Room(models.Model):
    number = models.IntegerField(unique=True)

class HotelReservation(models.Model):
    room = models.ForeignKey("Room", on_delete=models.CASCADE)
```

(continues on next page)

(continued from previous page)

```
start = models.DateTimeField()
end = models.DateTimeField()
requirements = models.JSONField(blank=True, null=True)
```

```
>>> from django.contrib.postgres.aggregates import JSONBAgg
>>> Room.objects.annotate(
...     requirements=JSONBAgg(
...         "hotelreservation__requirements",
...         ordering="-hotelreservation__start",
...     )
... ).filter(requirements__0__sea_view=True).values("number", "requirements")
<QuerySet [{'number': 102, 'requirements': [
    {'parking': False, 'sea_view': True, 'double_bed': False},
    {'parking': True, 'double_bed': True}
]]]>
```

Deprecated since version 4.0: If there are no rows and `default` is not provided, `JSONBAgg` returns an empty list instead of `None`. This behavior is deprecated and will be removed in Django 5.0. If you need it, explicitly set `default` to `Value(' [] ')`.

StringAgg

class `StringAgg`(expression, delimiter, distinct=False, filter=None, default=None, ordering=())

Returns the input values concatenated into a string, separated by the `delimiter` string, or `default` if there are no values.

delimiter

Required argument. Needs to be a string.

distinct

An optional boolean argument that determines if concatenated values will be distinct. Defaults to `False`.

ordering

An optional string of a field name (with an optional `"-"` prefix which indicates descending order) or an expression (or a tuple or list of strings and/or expressions) that specifies the ordering of the elements in the result string.

Examples are the same as for [*ArrayAgg.ordering*](#).

Usage example:

```
class Publication(models.Model):
    title = models.CharField(max_length=30)

class Article(models.Model):
    headline = models.CharField(max_length=100)
    publications = models.ManyToManyField(Publication)
```

```
>>> article = Article.objects.create(headline="NASA uses Python")
>>> article.publications.create(title="The Python Journal")
<Publication: Publication object (1)>
>>> article.publications.create(title="Science News")
<Publication: Publication object (2)>
>>> from django.contrib.postgres.aggregates import StringAgg
>>> Article.objects.annotate(
...     publication_names=StringAgg(
...         "publications__title",
...         delimiter=", ",
...         ordering="publications__title",
...     )
... ).values("headline", "publication_names")
<QuerySet [{
    'headline': 'NASA uses Python', 'publication_names': 'Science News, The Python Journal'
}]>
```

Deprecated since version 4.0: If there are no rows and `default` is not provided, `StringAgg` returns an empty string instead of `None`. This behavior is deprecated and will be removed in Django 5.0. If you need it, explicitly set `default` to `Value('')`.

Aggregate functions for statistics

y and x

The arguments `y` and `x` for all these functions can be the name of a field or an expression returning a numeric data. Both are required.

Corr

```
class Corr(y, x, filter=None, default=None)
```

Returns the correlation coefficient as a `float`, or `default` if there aren't any matching rows.

CovarPop

```
class CovarPop(y, x, sample=False, filter=None, default=None)
```

Returns the population covariance as a `float`, or `default` if there aren't any matching rows.

`sample`

Optional. By default `CovarPop` returns the general population covariance. However, if `sample=True`, the return value will be the sample population covariance.

RegrAvgX

```
class RegrAvgX(y, x, filter=None, default=None)
```

Returns the average of the independent variable ($\text{sum}(x)/N$) as a `float`, or `default` if there aren't any matching rows.

RegrAvgY

```
class RegrAvgY(y, x, filter=None, default=None)
```

Returns the average of the dependent variable ($\text{sum}(y)/N$) as a `float`, or `default` if there aren't any matching rows.

RegrCount

```
class RegrCount(y, x, filter=None)
```

Returns an `int` of the number of input rows in which both expressions are not null.

Note: The `default` argument is not supported.

RegrIntercept

```
class RegrIntercept(y, x, filter=None, default=None)
```

Returns the y-intercept of the least-squares-fit linear equation determined by the (x, y) pairs as a float, or default if there aren't any matching rows.

RegrR2

```
class RegrR2(y, x, filter=None, default=None)
```

Returns the square of the correlation coefficient as a float, or default if there aren't any matching rows.

RegrSlope

```
class RegrSlope(y, x, filter=None, default=None)
```

Returns the slope of the least-squares-fit linear equation determined by the (x, y) pairs as a float, or default if there aren't any matching rows.

RegrSXX

```
class RegrSXX(y, x, filter=None, default=None)
```

Returns $\text{sum}(x^2) - \text{sum}(x)^2/N$ ("sum of squares" of the independent variable) as a float, or default if there aren't any matching rows.

RegrSXY

```
class RegrSXY(y, x, filter=None, default=None)
```

Returns $\text{sum}(x*y) - \text{sum}(x) * \text{sum}(y)/N$ ("sum of products" of independent times dependent variable) as a float, or default if there aren't any matching rows.

RegrSYY

```
class RegrSYY(y, x, filter=None, default=None)
```

Returns $\text{sum}(y^2) - \text{sum}(y)^2/N$ ("sum of squares" of the dependent variable) as a float, or default if there aren't any matching rows.

Usage examples

We will use this example table:

FIELD1	FIELD2	FIELD3
foo	1	13
bar	2	(null)
test	3	13

Here' s some examples of some of the general-purpose aggregation functions:

```
>>> TestModel.objects.aggregate(result=StringAgg("field1", delimiter=";"))
{'result': 'foo;bar;test'}
>>> TestModel.objects.aggregate(result=ArrayAgg("field2"))
{'result': [1, 2, 3]}
>>> TestModel.objects.aggregate(result=ArrayAgg("field1"))
{'result': ['foo', 'bar', 'test']}
```

The next example shows the usage of statistical aggregate functions. The underlying math will be not described (you can read about this, for example, at [wikipedia](#)):

```
>>> TestModel.objects.aggregate(count=RegrCount(y="field3", x="field2"))
{'count': 2}
>>> TestModel.objects.aggregate(
...     avgx=RegrAvgX(y="field3", x="field2"), avgy=RegrAvgY(y="field3", x="field2")
... )
{'avgx': 2, 'avgy': 13}
```

PostgreSQL specific database constraints

PostgreSQL supports additional data integrity constraints available from the `django.contrib.postgres.constraints` module. They are added in the model *Meta.constraints* option.

ExclusionConstraint

```
class ExclusionConstraint(*, name, expressions, index_type=None, condition=None, deferrable=None,
                          include=None, opclasses=(), violation_error_message=None)
```

Creates an exclusion constraint in the database. Internally, PostgreSQL implements exclusion constraints using indexes. The default index type is `GiST`. To use them, you need to activate the `btree_gist` extension on PostgreSQL. You can install it using the *BtreeGistExtension* migration operation.

If you attempt to insert a new row that conflicts with an existing row, an *IntegrityError* is raised. Similarly, when update conflicts with an existing row.

Exclusion constraints are checked during the [model validation](#).

In older versions, exclusion constraints were not checked during model validation.

name

`ExclusionConstraint.name`

See *[BaseConstraint.name](#)*.

expressions

`ExclusionConstraint.expressions`

An iterable of 2-tuples. The first element is an expression or string. The second element is an SQL operator represented as a string. To avoid typos, you may use *[RangeOperators](#)* which maps the operators with strings. For example:

```
expressions = [
    ("timespan", RangeOperators.ADJACENT_TO),
    (F("room"), RangeOperators.EQUAL),
]
```

Restrictions on operators.

Only commutative operators can be used in exclusion constraints.

The *[OpClass\(\)](#)* expression can be used to specify a custom [operator class](#) for the constraint expressions. For example:

```
expressions = [
    (OpClass("circle", name="circle_ops"), RangeOperators.OVERLAPS),
]
```

creates an exclusion constraint on `circle` using `circle_ops`.

Support for the `OpClass()` expression was added.

`index_type`

`ExclusionConstraint.index_type`

The index type of the constraint. Accepted values are GIST or SPGIST. Matching is case insensitive. If not provided, the default index type is GIST.

`condition`

`ExclusionConstraint.condition`

A *Q* object that specifies the condition to restrict a constraint to a subset of rows. For example, `condition=Q(cancelled=False)`.

These conditions have the same database restrictions as *django.db.models.Index.condition*.

`deferrable`

`ExclusionConstraint.deferrable`

Set this parameter to create a deferrable exclusion constraint. Accepted values are `Deferrable.DEFERRED` or `Deferrable.IMMEDIATE`. For example:

```
from django.contrib.postgres.constraints import ExclusionConstraint
from django.contrib.postgres.fields import RangeOperators
from django.db.models import Deferrable

ExclusionConstraint(
    name="exclude_overlapping_deferred",
    expressions=[
        ("timespan", RangeOperators.OVERLAPS),
    ],
    deferrable=Deferrable.DEFERRED,
)
```

By default constraints are not deferred. A deferred constraint will not be enforced until the end of the transaction. An immediate constraint will be enforced immediately after every command.

Warning: Deferred exclusion constraints may lead to a [performance penalty](#).

`include`

`ExclusionConstraint.include`

A list or tuple of the names of the fields to be included in the covering exclusion constraint as non-key columns. This allows index-only scans to be used for queries that select only included fields (*include*) and filter only by indexed fields (*expressions*).

`include` is supported for GiST indexes. PostgreSQL 14+ also supports `include` for SP-GiST indexes.

Support for covering exclusion constraints using SP-GiST indexes on PostgreSQL 14+ was added.

`opclasses`

`ExclusionConstraint.opclasses`

The names of the PostgreSQL operator classes to use for this constraint. If you require a custom operator class, you must provide one for each expression in the constraint.

For example:

```
ExclusionConstraint(
    name="exclude_overlapping_opclasses",
    expressions=[("circle", RangeOperators.OVERLAPS)],
    opclasses=["circle_ops"],
)
```

creates an exclusion constraint on `circle` using `circle_ops`.

Deprecated since version 4.1: The `opclasses` parameter is deprecated in favor of using `OpClass()` in *expressions*.

`violation_error_message`

The error message used when `ValidationError` is raised during *model validation*. Defaults to `BaseConstraint.violation_error_message`.

Examples

The following example restricts overlapping reservations in the same room, not taking canceled reservations into account:

```
from django.contrib.postgres.constraints import ExclusionConstraint
from django.contrib.postgres.fields import DateTimeRangeField, RangeOperators
```

(continues on next page)

(continued from previous page)

```

from django.db import models
from django.db.models import Q

class Room(models.Model):
    number = models.IntegerField()

class Reservation(models.Model):
    room = models.ForeignKey("Room", on_delete=models.CASCADE)
    timespan = DateTimeRangeField()
    cancelled = models.BooleanField(default=False)

    class Meta:
        constraints = [
            ExclusionConstraint(
                name="exclude_overlapping_reservations",
                expressions=[
                    ("timespan", RangeOperators.OVERLAPS),
                    ("room", RangeOperators.EQUAL),
                ],
                condition=Q(cancelled=False),
            ),
        ]

```

In case your model defines a range using two fields, instead of the native PostgreSQL range types, you should write an expression that uses the equivalent function (e.g. `TsTzRange()`), and use the delimiters for the field. Most often, the delimiters will be `'[]'`, meaning that the lower bound is inclusive and the upper bound is exclusive. You may use the [RangeBoundary](#) that provides an expression mapping for the [range boundaries](#). For example:

```

from django.contrib.postgres.constraints import ExclusionConstraint
from django.contrib.postgres.fields import (
    DateTimeRangeField,
    RangeBoundary,
    RangeOperators,
)
from django.db import models
from django.db.models import Func, Q

class TsTzRange(Func):
    function = "TSTZRANGE"

```

(continues on next page)

(continued from previous page)

```

output_field = DateTimeRangeField()

class Reservation(models.Model):
    room = models.ForeignKey("Room", on_delete=models.CASCADE)
    start = models.DateTimeField()
    end = models.DateTimeField()
    cancelled = models.BooleanField(default=False)

    class Meta:
        constraints = [
            ExclusionConstraint(
                name="exclude_overlapping_reservations",
                expressions=[
                    (
                        TsTzRange("start", "end", RangeBoundary()),
                        RangeOperators.OVERLAPS,
                    ),
                    ("room", RangeOperators.EQUAL),
                ],
                condition=Q(cancelled=False),
            ),
        ]

```

PostgreSQL specific query expressions

These expressions are available from the `django.contrib.postgres.expressions` module.

ArraySubquery() expressions

```
class ArraySubquery(queryset)
```

`ArraySubquery` is a *Subquery* that uses the PostgreSQL `ARRAY` constructor to build a list of values from the queryset, which must use *QuerySet.values()* to return only a single column.

This class differs from *ArrayAgg* in the way that it does not act as an aggregate function and does not require an SQL `GROUP BY` clause to build the list of values.

For example, if you want to annotate all related books to an author as JSON objects:

```

>>> from django.db.models import OuterRef
>>> from django.db.models.functions import JSONObject
>>> from django.contrib.postgres.expressions import ArraySubquery

```

(continues on next page)

(continued from previous page)

```
>>> books = Book.objects.filter(author=OuterRef("pk")).values(
...     json=JSONObject(title="title", pages="pages")
... )
>>> author = Author.objects.annotate(books=ArraySubquery(books)).first()
>>> author.books
[{'title': 'Solaris', 'pages': 204}, {'title': 'The Cyberiad', 'pages': 295}]
```

PostgreSQL specific model fields

All of these fields are available from the `django.contrib.postgres.fields` module.

Indexing these fields

Index and *Field.db_index* both create a B-tree index, which isn't particularly helpful when querying complex data types. Indexes such as *GinIndex* and *GistIndex* are better suited, though the index choice is dependent on the queries that you're using. Generally, GiST may be a good choice for the *range fields* and *HStoreField*, and GIN may be helpful for *ArrayField*.

ArrayField

```
class ArrayField(base_field, size=None, **options)
```

A field for storing lists of data. Most field types can be used, and you pass another field instance as the *base_field*. You may also specify a *size*. *ArrayField* can be nested to store multi-dimensional arrays.

If you give the field a *default*, ensure it's a callable such as `list` (for an empty default) or a callable that returns a list (such as a function). Incorrectly using `default=[]` creates a mutable default that is shared between all instances of *ArrayField*.

base_field

This is a required argument.

Specifies the underlying data type and behavior for the array. It should be an instance of a subclass of *Field*. For example, it could be an *IntegerField* or a *CharField*. Most field types are permitted, with the exception of those handling relational data (*ForeignKey*, *OneToOneField* and *ManyToManyField*) and file fields (*FileField* and *ImageField*).

It is possible to nest array fields - you can specify an instance of *ArrayField* as the *base_field*. For example:

```

from django.contrib.postgres.fields import ArrayField
from django.db import models

class ChessBoard(models.Model):
    board = ArrayField(
        ArrayField(
            models.CharField(max_length=10, blank=True),
            size=8,
        ),
        size=8,
    )

```

Transformation of values between the database and the model, validation of data and configuration, and serialization are all delegated to the underlying base field.

size

This is an optional argument.

If passed, the array will have a maximum size as specified. This will be passed to the database, although PostgreSQL at present does not enforce the restriction.

Note: When nesting `ArrayField`, whether you use the `size` parameter or not, PostgreSQL requires that the arrays are rectangular:

```

from django.contrib.postgres.fields import ArrayField
from django.db import models

class Board(models.Model):
    pieces = ArrayField(ArrayField(models.IntegerField()))

# Valid
Board(
    pieces=[
        [2, 3],
        [2, 1],
    ]
)

# Not valid
Board(
    pieces=[

```

(continues on next page)

(continued from previous page)

```
        [2, 3],  
        [2],  
    ]  
)
```

If irregular shapes are required, then the underlying field should be made nullable and the values padded with `None`.

Querying ArrayField

There are a number of custom lookups and transforms for *ArrayField*. We will use the following example model:

```
from django.contrib.postgres.fields import ArrayField  
from django.db import models  
  
class Post(models.Model):  
    name = models.CharField(max_length=200)  
    tags = ArrayField(models.CharField(max_length=200), blank=True)  
  
    def __str__(self):  
        return self.name
```

`contains`

The *contains* lookup is overridden on *ArrayField*. The returned objects will be those where the values passed are a subset of the data. It uses the SQL operator `@>`. For example:

```
>>> Post.objects.create(name="First post", tags=["thoughts", "django"])  
>>> Post.objects.create(name="Second post", tags=["thoughts"])  
>>> Post.objects.create(name="Third post", tags=["tutorial", "django"])  
  
>>> Post.objects.filter(tags__contains=["thoughts"])  
<QuerySet [Post: First post, Post: Second post]>  
  
>>> Post.objects.filter(tags__contains=["django"])  
<QuerySet [Post: First post, Post: Third post]>  
  
>>> Post.objects.filter(tags__contains=["django", "thoughts"])  
<QuerySet [Post: First post]>
```

contained_by

This is the inverse of the *contains* lookup - the objects returned will be those where the data is a subset of the values passed. It uses the SQL operator `<@`. For example:

```
>>> Post.objects.create(name="First post", tags=["thoughts", "django"])
>>> Post.objects.create(name="Second post", tags=["thoughts"])
>>> Post.objects.create(name="Third post", tags=["tutorial", "django"])

>>> Post.objects.filter(tags__contained_by=["thoughts", "django"])
<QuerySet [<Post: First post>, <Post: Second post>]>

>>> Post.objects.filter(tags__contained_by=["thoughts", "django", "tutorial"])
<QuerySet [<Post: First post>, <Post: Second post>, <Post: Third post>]>
```

overlap

Returns objects where the data shares any results with the values passed. Uses the SQL operator `&&`. For example:

```
>>> Post.objects.create(name="First post", tags=["thoughts", "django"])
>>> Post.objects.create(name="Second post", tags=["thoughts", "tutorial"])
>>> Post.objects.create(name="Third post", tags=["tutorial", "django"])

>>> Post.objects.filter(tags__overlap=["thoughts"])
<QuerySet [<Post: First post>, <Post: Second post>]>

>>> Post.objects.filter(tags__overlap=["thoughts", "tutorial"])
<QuerySet [<Post: First post>, <Post: Second post>, <Post: Third post>]>

>>> Post.objects.filter(tags__overlap=Post.objects.values_list("tags"))
<QuerySet [<Post: First post>, <Post: Second post>, <Post: Third post>]>
```

Support for `QuerySet.values()` and `values_list()` as a right-hand side was added.

len

Returns the length of the array. The lookups available afterward are those available for *IntegerField*. For example:

```
>>> Post.objects.create(name="First post", tags=["thoughts", "django"])
>>> Post.objects.create(name="Second post", tags=["thoughts"])
```

(continues on next page)

(continued from previous page)

```
>>> Post.objects.filter(tags__len=1)
<QuerySet [<Post: Second post>]>
```

Index transforms

Index transforms index into the array. Any non-negative integer can be used. There are no errors if it exceeds the *size* of the array. The lookups available after the transform are those from the *base_field*. For example:

```
>>> Post.objects.create(name="First post", tags=["thoughts", "django"])
>>> Post.objects.create(name="Second post", tags=["thoughts"])

>>> Post.objects.filter(tags__0="thoughts")
<QuerySet [<Post: First post>, <Post: Second post>]>

>>> Post.objects.filter(tags__1__iexact="Django")
<QuerySet [<Post: First post>]>

>>> Post.objects.filter(tags__276="javascript")
<QuerySet []>
```

Note: PostgreSQL uses 1-based indexing for array fields when writing raw SQL. However these indexes and those used in *slices* use 0-based indexing to be consistent with Python.

Slice transforms

Slice transforms take a slice of the array. Any two non-negative integers can be used, separated by a single underscore. The lookups available after the transform do not change. For example:

```
>>> Post.objects.create(name="First post", tags=["thoughts", "django"])
>>> Post.objects.create(name="Second post", tags=["thoughts"])
>>> Post.objects.create(name="Third post", tags=["django", "python", "thoughts"])

>>> Post.objects.filter(tags__0_1=["thoughts"])
<QuerySet [<Post: First post>, <Post: Second post>]>

>>> Post.objects.filter(tags__0_2__contains=["thoughts"])
<QuerySet [<Post: First post>, <Post: Second post>]>
```

Note: PostgreSQL uses 1-based indexing for array fields when writing raw SQL. However these slices and those used in *indexes* use 0-based indexing to be consistent with Python.

Multidimensional arrays with indexes and slices

PostgreSQL has some rather esoteric behavior when using indexes and slices on multidimensional arrays. It will always work to use indexes to reach down to the final underlying data, but most other slices behave strangely at the database level and cannot be supported in a logical, consistent fashion by Django.

CIText fields

class CIText(options)**

Deprecated since version 4.2.

A mixin to create case-insensitive text fields backed by the `citext` type. Read about [the performance considerations](#) prior to using it.

To use `citext`, use the *CITextExtension* operation to [set up the citext extension](#) in PostgreSQL before the first `CreateModel` migration operation.

If you're using an *ArrayField* of `CIText` fields, you must add `'django.contrib.postgres'` in your *INSTALLED_APPS*, otherwise field values will appear as strings like `'{thoughts,django}'`.

Several fields that use the mixin are provided:

class CICharField(options)**

Deprecated since version 4.2: `CICharField` is deprecated in favor of `CharField(db_collation="...")` with a case-insensitive non-deterministic collation.

class CIEmailField(options)**

Deprecated since version 4.2: `CIEmailField` is deprecated in favor of `EmailField(db_collation="...")` with a case-insensitive non-deterministic collation.

class CITextField(options)**

Deprecated since version 4.2: `CITextField` is deprecated in favor of `TextField(db_collation="...")` with a case-insensitive non-deterministic collation.

These fields subclass *CharField*, *EmailField*, and *TextField*, respectively.

`max_length` won't be enforced in the database since `citext` behaves similar to PostgreSQL's `text` type.

Case-insensitive collations

It's preferable to use non-deterministic collations instead of the `citext` extension. You can create them using the `CreateCollation` migration operation. For more details, see [Managing collations using migrations](#) and the PostgreSQL documentation about [non-deterministic collations](#).

HStoreField

```
class HStoreField(**options)
```

A field for storing key-value pairs. The Python data type used is a `dict`. Keys must be strings, and values may be either strings or nulls (`None` in Python).

To use this field, you'll need to:

1. Add `'django.contrib.postgres'` in your [INSTALLED_APPS](#).
2. Set up the [hstore](#) extension in PostgreSQL.

You'll see an error like `can't adapt type 'dict'` if you skip the first step, or type `"hstore"` does not exist if you skip the second.

Note: On occasions it may be useful to require or restrict the keys which are valid for a given field. This can be done using the [KeysValidator](#).

Querying HStoreField

In addition to the ability to query by key, there are a number of custom lookups available for `HStoreField`.

We will use the following example model:

```
from django.contrib.postgres.fields import HStoreField
from django.db import models

class Dog(models.Model):
    name = models.CharField(max_length=200)
    data = HStoreField()

    def __str__(self):
        return self.name
```

Key lookups

To query based on a given key, you can use that key as the lookup name:

```
>>> Dog.objects.create(name="Rufus", data={"breed": "labrador"})
>>> Dog.objects.create(name="Meg", data={"breed": "collie"})

>>> Dog.objects.filter(data__breed="collie")
<QuerySet [<Dog: Meg>]>
```

You can chain other lookups after key lookups:

```
>>> Dog.objects.filter(data__breed__contains="l")
<QuerySet [<Dog: Rufus>, <Dog: Meg>]>
```

or use `F()` expressions to annotate a key value. For example:

```
>>> from django.db.models import F
>>> rufus = Dog.objects.annotate(breed=F("data__breed"))[0]
>>> rufus.breed
'labrador'
```

If the key you wish to query by clashes with the name of another lookup, you need to use the *hstorefield.contains* lookup instead.

Note: Key transforms can also be chained with: *contains*, *icontains*, *endswith*, *iendswith*, *iexact*, *regex*, *iregex*, *startswith*, and *istartswith* lookups.

Warning: Since any string could be a key in a hstore value, any lookup other than those listed below will be interpreted as a key lookup. No errors are raised. Be extra careful for typing mistakes, and always check your queries work as you intend.

contains

The *contains* lookup is overridden on *HStoreField*. The returned objects are those where the given dict of key-value pairs are all contained in the field. It uses the SQL operator `@>`. For example:

```
>>> Dog.objects.create(name="Rufus", data={"breed": "labrador", "owner": "Bob"})
>>> Dog.objects.create(name="Meg", data={"breed": "collie", "owner": "Bob"})
>>> Dog.objects.create(name="Fred", data={})
```

(continues on next page)

(continued from previous page)

```
>>> Dog.objects.filter(data__contains={"owner": "Bob"})
<QuerySet [<Dog: Rufus>, <Dog: Meg>]>

>>> Dog.objects.filter(data__contains={"breed": "collie"})
<QuerySet [<Dog: Meg>]>
```

contained_by

This is the inverse of the *contains* lookup - the objects returned will be those where the key-value pairs on the object are a subset of those in the value passed. It uses the SQL operator `<@`. For example:

```
>>> Dog.objects.create(name="Rufus", data={"breed": "labrador", "owner": "Bob"})
>>> Dog.objects.create(name="Meg", data={"breed": "collie", "owner": "Bob"})
>>> Dog.objects.create(name="Fred", data={})

>>> Dog.objects.filter(data__contained_by={"breed": "collie", "owner": "Bob"})
<QuerySet [<Dog: Meg>, <Dog: Fred>]>

>>> Dog.objects.filter(data__contained_by={"breed": "collie"})
<QuerySet [<Dog: Fred>]>
```

has_key

Returns objects where the given key is in the data. Uses the SQL operator `?`. For example:

```
>>> Dog.objects.create(name="Rufus", data={"breed": "labrador"})
>>> Dog.objects.create(name="Meg", data={"breed": "collie", "owner": "Bob"})

>>> Dog.objects.filter(data__has_key="owner")
<QuerySet [<Dog: Meg>]>
```

has_any_keys

Returns objects where any of the given keys are in the data. Uses the SQL operator `?|`. For example:

```
>>> Dog.objects.create(name="Rufus", data={"breed": "labrador"})
>>> Dog.objects.create(name="Meg", data={"owner": "Bob"})
>>> Dog.objects.create(name="Fred", data={})
```

(continues on next page)

(continued from previous page)

```
>>> Dog.objects.filter(data__has_any_keys=["owner", "breed"])
<QuerySet [<Dog: Rufus>, <Dog: Meg>]>
```

has_keys

Returns objects where all of the given keys are in the data. Uses the SQL operator `?&`. For example:

```
>>> Dog.objects.create(name="Rufus", data={})
>>> Dog.objects.create(name="Meg", data={"breed": "collie", "owner": "Bob"})

>>> Dog.objects.filter(data__has_keys=["breed", "owner"])
<QuerySet [<Dog: Meg>]>
```

keys

Returns objects where the array of keys is the given value. Note that the order is not guaranteed to be reliable, so this transform is mainly useful for using in conjunction with lookups on *ArrayField*. Uses the SQL function `akeys()`. For example:

```
>>> Dog.objects.create(name="Rufus", data={"toy": "bone"})
>>> Dog.objects.create(name="Meg", data={"breed": "collie", "owner": "Bob"})

>>> Dog.objects.filter(data__keys__overlap=["breed", "toy"])
<QuerySet [<Dog: Rufus>, <Dog: Meg>]>
```

values

Returns objects where the array of values is the given value. Note that the order is not guaranteed to be reliable, so this transform is mainly useful for using in conjunction with lookups on *ArrayField*. Uses the SQL function `avals()`. For example:

```
>>> Dog.objects.create(name="Rufus", data={"breed": "labrador"})
>>> Dog.objects.create(name="Meg", data={"breed": "collie", "owner": "Bob"})

>>> Dog.objects.filter(data__values__contains=["collie"])
<QuerySet [<Dog: Meg>]>
```

Range Fields

There are five range field types, corresponding to the built-in range types in PostgreSQL. These fields are used to store a range of values; for example the start and end timestamps of an event, or the range of ages an activity is suitable for.

All of the range fields translate to `psycopg Range` objects in Python, but also accept tuples as input if no bounds information is necessary. The default is lower bound included, upper bound excluded, that is `[]` (see the PostgreSQL documentation for details about [different bounds](#)). The default bounds can be changed for non-discrete range fields (*`DateTimeRangeField`* and *`DecimalRangeField`*) by using the `default_bounds` argument.

`IntegerRangeField`

```
class IntegerRangeField(**options)
```

Stores a range of integers. Based on an *`IntegerField`*. Represented by an `int4range` in the database and a `django.db.backends.postgresql.psycopg_any.NumericRange` in Python.

Regardless of the bounds specified when saving the data, PostgreSQL always returns a range in a canonical form that includes the lower bound and excludes the upper bound, that is `[]`.

`BigIntegerRangeField`

```
class BigIntegerRangeField(**options)
```

Stores a range of large integers. Based on a *`BigIntegerField`*. Represented by an `int8range` in the database and a `django.db.backends.postgresql.psycopg_any.NumericRange` in Python.

Regardless of the bounds specified when saving the data, PostgreSQL always returns a range in a canonical form that includes the lower bound and excludes the upper bound, that is `[]`.

`DecimalRangeField`

```
class DecimalRangeField(default_bounds='[]', **options)
```

Stores a range of floating point values. Based on a *`DecimalField`*. Represented by a `numrange` in the database and a `django.db.backends.postgresql.psycopg_any.NumericRange` in Python.

`default_bounds`

Optional. The value of bounds for list and tuple inputs. The default is lower bound included, upper bound excluded, that is `[]` (see the PostgreSQL documentation for details about [different bounds](#)). `default_bounds` is not used for `django.db.backends.postgresql.psycopg_any.NumericRange` inputs.

DateTimeRangeField

```
class DateTimeRangeField(default_bounds='[]', **options)
```

Stores a range of timestamps. Based on a *DateTimeField*. Represented by a `tstzrange` in the database and a `django.db.backends.postgresql.psycopg_any.DateTimeTZRange` in Python.

default_bounds

Optional. The value of `bounds` for list and tuple inputs. The default is lower bound included, upper bound excluded, that is `[]` (see the PostgreSQL documentation for details about [different bounds](#)). `default_bounds` is not used for `django.db.backends.postgresql.psycopg_any.DateTimeTZRange` inputs.

DateRangeField

```
class DateRangeField(**options)
```

Stores a range of dates. Based on a *DateField*. Represented by a `daterange` in the database and a `django.db.backends.postgresql.psycopg_any.DateRange` in Python.

Regardless of the bounds specified when saving the data, PostgreSQL always returns a range in a canonical form that includes the lower bound and excludes the upper bound, that is `[]`.

Querying Range Fields

There are a number of custom lookups and transforms for range fields. They are available on all the above fields, but we will use the following example model:

```
from django.contrib.postgres.fields import IntegerRangeField
from django.db import models

class Event(models.Model):
    name = models.CharField(max_length=200)
    ages = IntegerRangeField()
    start = models.DateTimeField()

    def __str__(self):
        return self.name
```

We will also use the following example objects:

```
>>> import datetime
>>> from django.utils import timezone
>>> now = timezone.now()
```

(continues on next page)

(continued from previous page)

```
>>> Event.objects.create(name="Soft play", ages=(0, 10), start=now)
>>> Event.objects.create(
...     name="Pub trip", ages=(21, None), start=now - datetime.timedelta(days=1)
... )
```

and `NumericRange`:

```
>>> from django.db.backends.postgresql.psycopg_any import NumericRange
```

Containment functions

As with other PostgreSQL fields, there are three standard containment operators: `contains`, `contained_by` and `overlap`, using the SQL operators `@>`, `<@`, and `&&` respectively.

`contains`

```
>>> Event.objects.filter(ages__contains=NumericRange(4, 5))
<QuerySet [<Event: Soft play>]>
```

`contained_by`

```
>>> Event.objects.filter(ages__contained_by=NumericRange(0, 15))
<QuerySet [<Event: Soft play>]>
```

The `contained_by` lookup is also available on the non-range field types: *SmallAutoField*, *AutoField*, *BigAutoField*, *SmallIntegerField*, *IntegerField*, *BigIntegerField*, *DecimalField*, *FloatField*, *DateField*, and *DateTimeField*. For example:

```
>>> from django.db.backends.postgresql.psycopg_any import DateTimeTZRange
>>> Event.objects.filter(
...     start__contained_by=DateTimeTZRange(
...         timezone.now() - datetime.timedelta(hours=1),
...         timezone.now() + datetime.timedelta(hours=1),
...     ),
... )
<QuerySet [<Event: Soft play>]>
```

`overlap`

```
>>> Event.objects.filter(ages__overlap=NumericRange(8, 12))
<QuerySet [<Event: Soft play>]>
```

Comparison functions

Range fields support the standard lookups: `lt`, `gt`, `lte` and `gte`. These are not particularly helpful - they compare the lower bounds first and then the upper bounds only if necessary. This is also the strategy used to order by a range field. It is better to use the specific range comparison operators.

`fully_lt`

The returned ranges are strictly less than the passed range. In other words, all the points in the returned range are less than all those in the passed range.

```
>>> Event.objects.filter(ages__fully_lt=NumericRange(11, 15))
<QuerySet [<Event: Soft play>]>
```

`fully_gt`

The returned ranges are strictly greater than the passed range. In other words, the all the points in the returned range are greater than all those in the passed range.

```
>>> Event.objects.filter(ages__fully_gt=NumericRange(11, 15))
<QuerySet [<Event: Pub trip>]>
```

`not_lt`

The returned ranges do not contain any points less than the passed range, that is the lower bound of the returned range is at least the lower bound of the passed range.

```
>>> Event.objects.filter(ages__not_lt=NumericRange(0, 15))
<QuerySet [<Event: Soft play>, <Event: Pub trip>]>
```

`not_gt`

The returned ranges do not contain any points greater than the passed range, that is the upper bound of the returned range is at most the upper bound of the passed range.

```
>>> Event.objects.filter(ages__not_gt=NumericRange(3, 10))
<QuerySet [<Event: Soft play>]>
```

`adjacent_to`

The returned ranges share a bound with the passed range.

```
>>> Event.objects.filter(ages__adjacent_to=NumericRange(10, 21))
<QuerySet [<Event: Soft play>, <Event: Pub trip>]>
```

Querying using the bounds

Range fields support several extra lookups.

`startswith`

Returned objects have the given lower bound. Can be chained to valid lookups for the base field.

```
>>> Event.objects.filter(ages__startswith=21)
<QuerySet [<Event: Pub trip>]>
```

`endswith`

Returned objects have the given upper bound. Can be chained to valid lookups for the base field.

```
>>> Event.objects.filter(ages__endswith=10)
<QuerySet [<Event: Soft play>]>
```

`isempty`

Returned objects are empty ranges. Can be chained to valid lookups for a *BooleanField*.

```
>>> Event.objects.filter(ages__isempty=True)
<QuerySet []>
```

`lower_inc`

Returns objects that have inclusive or exclusive lower bounds, depending on the boolean value passed. Can be chained to valid lookups for a *BooleanField*.

```
>>> Event.objects.filter(ages__lower_inc=True)
<QuerySet [<Event: Soft play>, <Event: Pub trip>]>
```

`lower_inf`

Returns objects that have unbounded (infinite) or bounded lower bound, depending on the boolean value passed. Can be chained to valid lookups for a *BooleanField*.

```
>>> Event.objects.filter(ages__lower_inf=True)
<QuerySet []>
```

`upper_inc`

Returns objects that have inclusive or exclusive upper bounds, depending on the boolean value passed. Can be chained to valid lookups for a *BooleanField*.

```
>>> Event.objects.filter(ages__upper_inc=True)
<QuerySet []>
```

`upper_inf`

Returns objects that have unbounded (infinite) or bounded upper bound, depending on the boolean value passed. Can be chained to valid lookups for a *BooleanField*.

```
>>> Event.objects.filter(ages__upper_inf=True)
<QuerySet [<Event: Pub trip>]>
```

Defining your own range types

PostgreSQL allows the definition of custom range types. Django's model and form field implementations use base classes below, and `psycopg` provides a `register_range()` to allow use of custom range types.

```
class RangeField(**options)
    Base class for model range fields.

    base_field
        The model field class to use.

    range_type
        The range type to use.

    form_field
        The form field class to use. Should be a subclass of django.contrib.postgres.forms.BaseRangeField.

class django.contrib.postgres.forms.BaseRangeField
    Base class for form range fields.

    base_field
        The form field to use.

    range_type
        The range type to use.
```

Range operators

```
class RangeOperators
```

PostgreSQL provides a set of SQL operators that can be used together with the range data types (see [the PostgreSQL documentation for the full details of range operators](#)). This class is meant as a convenient method to avoid typos. The operator names overlap with the names of corresponding lookups.

```
class RangeOperators:
    EQUAL = "="
    NOT_EQUAL = "<>"
    CONTAINS = "@>"
    CONTAINED_BY = "<@"
    OVERLAPS = "&&"
    FULLY_LT = "<<"
    FULLY_GT = ">>"
    NOT_LT = "&>"
    NOT_GT = "&<"
    ADJACENT_TO = "-|-"
```

RangeBoundary() expressions

```
class RangeBoundary(inclusive_lower=True, inclusive_upper=False)
```

inclusive_lower

If True (default), the lower bound is inclusive '[' , otherwise it's exclusive '(' .

inclusive_upper

If False (default), the upper bound is exclusive ')' , otherwise it's inclusive ']' .

A `RangeBoundary()` expression represents the range boundaries. It can be used with a custom range functions that expected boundaries, for example to define *ExclusionConstraint*. See [the PostgreSQL documentation](#) for the full details.

PostgreSQL specific form fields and widgets

All of these fields and widgets are available from the `django.contrib.postgres.forms` module.

Fields

SimpleArrayField

```
class SimpleArrayField(base_field, delimiter=',', max_length=None, min_length=None)
```

A field which maps to an array. It is represented by an HTML `<input>`.

base_field

This is a required argument.

It specifies the underlying form field for the array. This is not used to render any HTML, but it is used to process the submitted data and validate it. For example:

```
>>> from django import forms
>>> from django.contrib.postgres.forms import SimpleArrayField

>>> class NumberListForm(forms.Form):
...     numbers = SimpleArrayField(forms.IntegerField())
...

>>> form = NumberListForm({"numbers": "1,2,3"})
>>> form.is_valid()
True
>>> form.cleaned_data
{'numbers': [1, 2, 3]}
```

(continues on next page)

(continued from previous page)

```
>>> form = NumberListForm({"numbers": "1,2,a"})
>>> form.is_valid()
False
```

delimiter

This is an optional argument which defaults to a comma: `,`. This value is used to split the submitted data. It allows you to chain `SimpleArrayField` for multidimensional data:

```
>>> from django import forms
>>> from django.contrib.postgres.forms import SimpleArrayField

>>> class GridForm(forms.Form):
...     places = SimpleArrayField(SimpleArrayField(IntegerField()), delimiter="|")
...

>>> form = GridForm({"places": "1,2|2,1|4,3"})
>>> form.is_valid()
True
>>> form.cleaned_data
{'places': [[1, 2], [2, 1], [4, 3]]}
```

Note: The field does not support escaping of the delimiter, so be careful in cases where the delimiter is a valid character in the underlying field. The delimiter does not need to be only one character.

max_length

This is an optional argument which validates that the array does not exceed the stated length.

min_length

This is an optional argument which validates that the array reaches at least the stated length.

User friendly forms

`SimpleArrayField` is not particularly user friendly in most cases, however it is a useful way to format data from a client-side widget for submission to the server.

SplitArrayField

```
class SplitArrayField(base_field, size, remove_trailing_nulls=False)
```

This field handles arrays by reproducing the underlying field a fixed number of times.

base_field

This is a required argument. It specifies the form field to be repeated.

size

This is the fixed number of times the underlying field will be used.

remove_trailing_nulls

By default, this is set to `False`. When `False`, each value from the repeated fields is stored. When set to `True`, any trailing values which are blank will be stripped from the result. If the underlying field has `required=True`, but `remove_trailing_nulls` is `True`, then null values are only allowed at the end, and will be stripped.

Some examples:

```
SplitArrayField(IntegerField(required=True), size=3, remove_trailing_nulls=False)

["1", "2", "3"] # -> [1, 2, 3]
["1", "2", ""] # -> ValidationError - third entry required.
["1", "", "3"] # -> ValidationError - second entry required.
["", "2", ""] # -> ValidationError - first and third entries required.

SplitArrayField(IntegerField(required=False), size=3, remove_trailing_nulls=False)

["1", "2", "3"] # -> [1, 2, 3]
["1", "2", ""] # -> [1, 2, None]
["1", "", "3"] # -> [1, None, 3]
["", "2", ""] # -> [None, 2, None]

SplitArrayField(IntegerField(required=True), size=3, remove_trailing_nulls=True)

["1", "2", "3"] # -> [1, 2, 3]
["1", "2", ""] # -> [1, 2]
["1", "", "3"] # -> ValidationError - second entry required.
["", "2", ""] # -> ValidationError - first entry required.

SplitArrayField(IntegerField(required=False), size=3, remove_trailing_nulls=True)

["1", "2", "3"] # -> [1, 2, 3]
["1", "2", ""] # -> [1, 2]
["1", "", "3"] # -> [1, None, 3]
```

(continues on next page)

(continued from previous page)

```
[ "", "2", "" ] # -> [None, 2]
```

HStoreField

class HStoreField

A field which accepts JSON encoded data for an *HStoreField*. It casts all values (except nulls) to strings. It is represented by an HTML `<textarea>`.

User friendly forms

HStoreField is not particularly user friendly in most cases, however it is a useful way to format data from a client-side widget for submission to the server.

Note: On occasions it may be useful to require or restrict the keys which are valid for a given field. This can be done using the *KeysValidator*.

Range Fields

This group of fields all share similar functionality for accepting range data. They are based on *MultiValueField*. They treat one omitted value as an unbounded range. They also validate that the lower bound is not greater than the upper bound. All of these fields use *RangeWidget*.

IntegerRangeField

class IntegerRangeField

Based on *IntegerField* and translates its input into `django.db.backends.postgresql.psycopg_any.NumericRange`. Default for *IntegerRangeField* and *BigIntegerRangeField*.

DecimalRangeField

class DecimalRangeField

Based on *DecimalField* and translates its input into `django.db.backends.postgresql.psycopg_any.NumericRange`. Default for *DecimalRangeField*.

`DateTimeRangeField`

`class DateTimeRangeField`

Based on *DateTimeField* and translates its input into `django.db.backends.postgresql.psycopg_any.DateTimeTZRange`. Default for *DateTimeRangeField*.

`DateRangeField`

`class DateRangeField`

Based on *DateField* and translates its input into `django.db.backends.postgresql.psycopg_any.DateRange`. Default for *DateRangeField*.

Widgets

`RangeWidget`

`class RangeWidget(base_widget, attrs=None)`

Widget used by all of the range fields. Based on *MultiWidget*.

RangeWidget has one required argument:

`base_widget`

A *RangeWidget* comprises a 2-tuple of `base_widget`.

`decompress(value)`

Takes a single “compressed” value of a field, for example a *DateRangeField*, and returns a tuple representing a lower and upper bound.

PostgreSQL specific database functions

All of these functions are available from the `django.contrib.postgres.functions` module.

`RandomUUID`

`class RandomUUID`

Returns a version 4 UUID.

On PostgreSQL < 13, the *pgcrypto* extension must be installed. You can use the *CryptoExtension* migration operation to install it.

Usage example:

```
>>> from django.contrib.postgres.functions import RandomUUID
>>> Article.objects.update(uuid=RandomUUID())
```

TransactionNow

```
class TransactionNow
```

Returns the date and time on the database server that the current transaction started. If you are not in a transaction it will return the date and time of the current statement. This is a complement to *django.db.models.functions.Now*, which returns the date and time of the current statement.

Note that only the outermost call to *atomic()* sets up a transaction and thus sets the time that *TransactionNow()* will return; nested calls create savepoints which do not affect the transaction time.

Usage example:

```
>>> from django.contrib.postgres.functions import TransactionNow
>>> Article.objects.filter(published__lte=TransactionNow())
<QuerySet [<Article: How to Django>]>
```

PostgreSQL specific model indexes

The following are PostgreSQL specific *indexes* available from the *django.contrib.postgres.indexes* module.

BloomIndex

```
class BloomIndex(*expressions, length=None, columns=(), **options)
```

Creates a *bloom* index.

To use this index access you need to activate the *bloom* extension on PostgreSQL. You can install it using the *BloomExtension* migration operation.

Provide an integer number of bits from 1 to 4096 to the *length* parameter to specify the length of each index entry. PostgreSQL's default is 80.

The *columns* argument takes a tuple or list of up to 32 values that are integer number of bits from 1 to 4095.

BrinIndex

```
class BrinIndex(*expressions, autosummarize=None, pages_per_range=None, **options)
```

Creates a [BRIN index](#).

Set the `autosummarize` parameter to `True` to enable [automatic summarization](#) to be performed by `autovacuum`.

The `pages_per_range` argument takes a positive integer.

BTreeIndex

```
class BTreeIndex(*expressions, fillfactor=None, **options)
```

Creates a B-Tree index.

Provide an integer value from 10 to 100 to the `fillfactor` parameter to tune how packed the index pages will be. PostgreSQL's default is 90.

GinIndex

```
class GinIndex(*expressions, fastupdate=None, gin_pending_list_limit=None, **options)
```

Creates a [gin index](#).

To use this index on data types not in the [built-in operator classes](#), you need to activate the [btree_gin extension](#) on PostgreSQL. You can install it using the [BtreeGinExtension](#) migration operation.

Set the `fastupdate` parameter to `False` to disable the [GIN Fast Update Technique](#) that's enabled by default in PostgreSQL.

Provide an integer number of kilobytes to the `gin_pending_list_limit` parameter to tune the maximum size of the GIN pending list which is used when `fastupdate` is enabled.

GistIndex

```
class GistIndex(*expressions, buffering=None, fillfactor=None, **options)
```

Creates a [GiST index](#). These indexes are automatically created on spatial fields with `spatial_index=True`. They're also useful on other types, such as [HStoreField](#) or the [range fields](#).

To use this index on data types not in the [built-in gist operator classes](#), you need to activate the [btree_gist extension](#) on PostgreSQL. You can install it using the [BtreeGistExtension](#) migration operation.

Set the `buffering` parameter to `True` or `False` to manually enable or disable [buffering build](#) of the index.

Provide an integer value from 10 to 100 to the `fillfactor` parameter to tune how packed the index pages will be. PostgreSQL's default is 90.

HashIndex

```
class HashIndex(*expressions, fillfactor=None, **options)
```

Creates a hash index.

Provide an integer value from 10 to 100 to the `fillfactor` parameter to tune how packed the index pages will be. PostgreSQL's default is 90.

SpGistIndex

```
class SpGistIndex(*expressions, fillfactor=None, **options)
```

Creates an SP-GiST index.

Provide an integer value from 10 to 100 to the `fillfactor` parameter to tune how packed the index pages will be. PostgreSQL's default is 90.

Support for covering SP-GiST indexes on PostgreSQL 14+ was added.

OpClass() expressions

```
class OpClass(expression, name)
```

An `OpClass()` expression represents the `expression` with a custom `operator class` that can be used to define functional indexes, functional unique constraints, or exclusion constraints. To use it, you need to add `'django.contrib.postgres'` in your `INSTALLED_APPS`. Set the `name` parameter to the name of the `operator class`.

For example:

```
Index(  
    OpClass(Lower("username"), name="varchar_pattern_ops"),  
    name="lower_username_idx",  
)
```

creates an index on `Lower('username')` using `varchar_pattern_ops`.

```
UniqueConstraint(  
    OpClass(Upper("description"), name="text_pattern_ops"),  
    name="upper_description_unique",  
)
```

creates a unique constraint on `Upper('description')` using `text_pattern_ops`.

```
ExclusionConstraint(
    name="exclude_overlapping_ops",
    expressions=[
        (OpClass("circle", name="circle_ops"), RangeOperators.OVERLAPS),
    ],
)
```

creates an exclusion constraint on `circle` using `circle_ops`.

Support for exclusion constraints was added.

PostgreSQL specific lookups

Trigram similarity

`trigram_similar`

The `trigram_similar` lookup allows you to perform trigram lookups, measuring the number of trigrams (three consecutive characters) shared, using a dedicated PostgreSQL extension. A trigram lookup is given an expression and returns results that have a similarity measurement greater than the current similarity threshold.

To use it, add `'django.contrib.postgres'` in your *INSTALLED_APPS* and activate the `pg_trgm` extension on PostgreSQL. You can install the extension using the *TrigramExtension* migration operation.

The `trigram_similar` lookup can be used on *CharField* and *TextField*:

```
>>> City.objects.filter(name__trigram_similar="Middlesbrough")
['<City: Middlesbrough>']
```

`trigram_word_similar`

The `trigram_word_similar` lookup allows you to perform trigram word similarity lookups using a dedicated PostgreSQL extension. It can be approximately understood as measuring the greatest number of trigrams shared between the parameter and any substring of the field. A trigram word lookup is given an expression and returns results that have a word similarity measurement greater than the current similarity threshold.

To use it, add `'django.contrib.postgres'` in your *INSTALLED_APPS* and activate the `pg_trgm` extension on PostgreSQL. You can install the extension using the *TrigramExtension* migration operation.

The `trigram_word_similar` lookup can be used on *CharField* and *TextField*:

```
>>> Sentence.objects.filter(name__trigram_word_similar="Middlesbrough")
['<Sentence: Gumby rides on the path of Middlesbrough>']
```

`trigram_strict_word_similar`

Similar to `trigram_word_similar`, except that it forces extent boundaries to match word boundaries.

To use it, add `'django.contrib.postgres'` in your `INSTALLED_APPS` and activate the `pg_trgm` extension on PostgreSQL. You can install the extension using the `TrigramExtension` migration operation.

The `trigram_strict_word_similar` lookup can be used on `CharField` and `TextField`.

Unaccent

The `unaccent` lookup allows you to perform accent-insensitive lookups using a dedicated PostgreSQL extension.

This lookup is implemented using `Transform`, so it can be chained with other lookup functions. To use it, you need to add `'django.contrib.postgres'` in your `INSTALLED_APPS` and activate the `unaccent` extension on PostgreSQL. The `UnaccentExtension` migration operation is available if you want to perform this activation using migrations).

The `unaccent` lookup can be used on `CharField` and `TextField`:

```
>>> City.objects.filter(name__unaccent="México")
['<City: Mexico>']

>>> User.objects.filter(first_name__unaccent__startswith="Jerem")
['<User: Jeremy>', '<User: Jérôme>', '<User: Jérémie>', '<User: Jeremie>']
```

Warning: `unaccent` lookups should perform fine in most use cases. However, queries using this filter will generally perform full table scans, which can be slow on large tables. In those cases, using dedicated full text indexing tools might be appropriate.

Database migration operations

All of these [operations](#) are available from the `django.contrib.postgres.operations` module.

Creating extension using migrations

You can create a PostgreSQL extension in your database using a migration file. This example creates an `hstore` extension, but the same principles apply for other extensions.

Set up the `hstore` extension in PostgreSQL before the first `CreateModel` or `AddField` operation that involves *HStoreField* by adding a migration with the *HStoreExtension* operation. For example:

```
from django.contrib.postgres.operations import HStoreExtension

class Migration(migrations.Migration):
    ...

    operations = [HStoreExtension(), ...]
```

The operation skips adding the extension if it already exists.

For most extensions, this requires a database user with superuser privileges. If the Django database user doesn't have the appropriate privileges, you'll have to create the extension outside of Django migrations with a user that has them. In that case, connect to your Django database and run the query `CREATE EXTENSION IF NOT EXISTS hstore;`.

CreateExtension

```
class CreateExtension(name)
```

An `Operation` subclass which installs a PostgreSQL extension. For common extensions, use one of the more specific subclasses below.

name

This is a required argument. The name of the extension to be installed.

`BloomExtension`

```
class BloomExtension
```

Installs the bloom extension.

`BtreeGinExtension`

```
class BtreeGinExtension
```

Installs the btree_gin extension.

`BtreeGistExtension`

```
class BtreeGistExtension
```

Installs the btree_gist extension.

`CITextExtension`

```
class CITextExtension
```

Installs the citext extension.

`CryptoExtension`

```
class CryptoExtension
```

Installs the pgcrypto extension.

`HStoreExtension`

```
class HStoreExtension
```

Installs the hstore extension and also sets up the connection to interpret hstore data for possible use in subsequent migrations.

`TrigramExtension`

```
class TrigramExtension
```

Installs the pg_trgm extension.

UnaccentExtension

```
class UnaccentExtension
```

Installs the unaccent extension.

Managing collations using migrations

If you need to filter or order a column using a particular collation that your operating system provides but PostgreSQL does not, you can manage collations in your database using a migration file. These collations can then be used with the `db_collation` parameter on *CharField*, *TextField*, and their subclasses.

For example, to create a collation for German phone book ordering:

```
from django.contrib.postgres.operations import CreateCollation

class Migration(migrations.Migration):
    ...

    operations = [
        CreateCollation(
            "case_insensitive",
            provider="icu",
            locale="und-u-ks-level2",
            deterministic=False,
        ),
        ...
    ]
```

```
class CreateCollation(name, locale, *, provider='libc', deterministic=True)
```

Creates a collation with the given `name`, `locale` and `provider`.

Set the `deterministic` parameter to `False` to create a non-deterministic collation, such as for case-insensitive filtering.

```
class RemoveCollation(name, locale, *, provider='libc', deterministic=True)
```

Removes the collations named `name`.

When reversed this is creating a collation with the provided `locale`, `provider`, and `deterministic` arguments. Therefore, `locale` is required to make this operation reversible.

Concurrent index operations

PostgreSQL supports the `CONCURRENTLY` option to `CREATE INDEX` and `DROP INDEX` statements to add and remove indexes without locking out writes. This option is useful for adding or removing an index in a live production database.

class `AddIndexConcurrently(model_name, index)`

Like *AddIndex*, but creates an index with the `CONCURRENTLY` option. This has a few caveats to be aware of when using this option, see [the PostgreSQL documentation of building indexes concurrently](#).

class `RemoveIndexConcurrently(model_name, name)`

Like *RemoveIndex*, but removes the index with the `CONCURRENTLY` option. This has a few caveats to be aware of when using this option, see [the PostgreSQL documentation](#).

Note: The `CONCURRENTLY` option is not supported inside a transaction (see [non-atomic migration](#)).

Adding constraints without enforcing validation

PostgreSQL supports the `NOT VALID` option with the `ADD CONSTRAINT` statement to add check constraints without enforcing validation on existing rows. This option is useful if you want to skip the potentially lengthy scan of the table to verify that all existing rows satisfy the constraint.

To validate check constraints created with the `NOT VALID` option at a later point of time, use the *ValidateConstraint* operation.

See [the PostgreSQL documentation](#) for more details.

class `AddConstraintNotValid(model_name, constraint)`

Like *AddConstraint*, but avoids validating the constraint on existing rows.

class `ValidateConstraint(model_name, name)`

Scans through the table and validates the given check constraint on existing rows.

Note: `AddConstraintNotValid` and `ValidateConstraint` operations should be performed in two separate migrations. Performing both operations in the same atomic migration has the same effect as *AddConstraint*, whereas performing them in a single non-atomic migration, may leave your database in an inconsistent state if the `ValidateConstraint` operation fails.

Full text search

The database functions in the `django.contrib.postgres.search` module ease the use of PostgreSQL's [full text search engine](#).

For the examples in this document, we'll use the models defined in [Making queries](#).

See also:

For a high-level overview of searching, see the [topic documentation](#).

The search lookup

A common way to use full text search is to search a single term against a single column in the database. For example:

```
>>> Entry.objects.filter(body_text__search="Cheese")
[<Entry: Cheese on Toast recipes>, <Entry: Pizza Recipes>]
```

This creates a `to_tsvector` in the database from the `body_text` field and a `plainto_tsquery` from the search term 'Cheese', both using the default database search configuration. The results are obtained by matching the query and the vector.

To use the search lookup, 'django.contrib.postgres' must be in your [INSTALLED_APPS](#).

SearchVector

```
class SearchVector(*expressions, config=None, weight=None)
```

Searching against a single field is great but rather limiting. The `Entry` instances we're searching belong to a `Blog`, which has a `tagline` field. To query against both fields, use a `SearchVector`:

```
>>> from django.contrib.postgres.search import SearchVector
>>> Entry.objects.annotate(
...     search=SearchVector("body_text", "blog__tagline"),
... ).filter(search="Cheese")
[<Entry: Cheese on Toast recipes>, <Entry: Pizza Recipes>]
```

The arguments to `SearchVector` can be any [Expression](#) or the name of a field. Multiple arguments will be concatenated together using a space so that the search document includes them all.

`SearchVector` objects can be combined together, allowing you to reuse them. For example:

```
>>> Entry.objects.annotate(
...     search=SearchVector("body_text") + SearchVector("blog__tagline"),
```

(continues on next page)

(continued from previous page)

```
... ).filter(search="Cheese")  
[<Entry: Cheese on Toast recipes>, <Entry: Pizza Recipes>]
```

See [Changing the search configuration](#) and [Weighting queries](#) for an explanation of the `config` and `weight` parameters.

SearchQuery

```
class SearchQuery(value, config=None, search_type='plain')
```

`SearchQuery` translates the terms the user provides into a search query object that the database compares to a search vector. By default, all the words the user provides are passed through the stemming algorithms, and then it looks for matches for all of the resulting terms.

If `search_type` is `'plain'`, which is the default, the terms are treated as separate keywords. If `search_type` is `'phrase'`, the terms are treated as a single phrase. If `search_type` is `'raw'`, then you can provide a formatted search query with terms and operators. If `search_type` is `'websearch'`, then you can provide a formatted search query, similar to the one used by web search engines. `'websearch'` requires PostgreSQL ≥ 11 . Read PostgreSQL's [Full Text Search docs](#) to learn about differences and syntax. Examples:

```
>>> from django.contrib.postgres.search import SearchQuery  
>>> SearchQuery('red tomato') # two keywords  
>>> SearchQuery('tomato red') # same results as above  
>>> SearchQuery('red tomato', search_type='phrase') # a phrase  
>>> SearchQuery('tomato red', search_type='phrase') # a different phrase  
>>> SearchQuery('"tomato" & ("red" | "green")', search_type='raw') # boolean operators  
>>> SearchQuery('"tomato" ("red" OR "green")', search_type='websearch') # websearch operators
```

`SearchQuery` terms can be combined logically to provide more flexibility:

```
>>> from django.contrib.postgres.search import SearchQuery  
>>> SearchQuery("meat") & SearchQuery("cheese") # AND  
>>> SearchQuery("meat") | SearchQuery("cheese") # OR  
>>> ~SearchQuery("meat") # NOT
```

See [Changing the search configuration](#) for an explanation of the `config` parameter.

SearchRank

```
class SearchRank(vector, query, weights=None, normalization=None, cover_density=False)
```

So far, we've returned the results for which any match between the vector and the query are possible. It's likely you may wish to order the results by some sort of relevancy. PostgreSQL provides a ranking function which takes into account how often the query terms appear in the document, how close together the terms are in the document, and how important the part of the document is where they occur. The better the match, the higher the value of the rank. To order by relevancy:

```
>>> from django.contrib.postgres.search import SearchQuery, SearchRank, SearchVector
>>> vector = SearchVector("body_text")
>>> query = SearchQuery("cheese")
>>> Entry.objects.annotate(rank=SearchRank(vector, query)).order_by("-rank")
[<Entry: Cheese on Toast recipes>, <Entry: Pizza recipes>]
```

See [Weighting queries](#) for an explanation of the `weights` parameter.

Set the `cover_density` parameter to `True` to enable the cover density ranking, which means that the proximity of matching query terms is taken into account.

Provide an integer to the `normalization` parameter to control rank normalization. This integer is a bit mask, so you can combine multiple behaviors:

```
>>> from django.db.models import Value
>>> Entry.objects.annotate(
...     rank=SearchRank(
...         vector,
...         query,
...         normalization=Value(2).bitor(Value(4)),
...     )
... )
```

The PostgreSQL documentation has more details about [different rank normalization options](#).

SearchHeadline

```
class SearchHeadline(expression, query, config=None, start_sel=None, stop_sel=None,
                    max_words=None, min_words=None, short_word=None, highlight_all=None,
                    max_fragments=None, fragment_delimiter=None)
```

Accepts a single text field or an expression, a query, a config, and a set of options. Returns highlighted search results.

Set the `start_sel` and `stop_sel` parameters to the string values to be used to wrap highlighted query terms in the document. PostgreSQL's defaults are `<b>` and `</b>`.

Provide integer values to the `max_words` and `min_words` parameters to determine the longest and shortest headlines. PostgreSQL's defaults are 35 and 15.

Provide an integer value to the `short_word` parameter to discard words of this length or less in each headline. PostgreSQL's default is 3.

Set the `highlight_all` parameter to `True` to use the whole document in place of a fragment and ignore `max_words`, `min_words`, and `short_word` parameters. That's disabled by default in PostgreSQL.

Provide a non-zero integer value to the `max_fragments` to set the maximum number of fragments to display. That's disabled by default in PostgreSQL.

Set the `fragment_delimiter` string parameter to configure the delimiter between fragments. PostgreSQL's default is " ... ".

The PostgreSQL documentation has more details on [highlighting search results](#).

Usage example:

```
>>> from django.contrib.postgres.search import SearchHeadline, SearchQuery
>>> query = SearchQuery("red tomato")
>>> entry = Entry.objects.annotate(
...     headline=SearchHeadline(
...         "body_text",
...         query,
...         start_sel="<span>",
...         stop_sel="</span>",
...     ),
... ).get()
>>> print(entry.headline)
Sandwich with <span>tomato</span> and <span>red</span> cheese.
```

See [Changing the search configuration](#) for an explanation of the `config` parameter.

Changing the search configuration

You can specify the `config` attribute to a [*SearchVector*](#) and [*SearchQuery*](#) to use a different search configuration. This allows using different language parsers and dictionaries as defined by the database:

```
>>> from django.contrib.postgres.search import SearchQuery, SearchVector
>>> Entry.objects.annotate(
...     search=SearchVector("body_text", config="french"),
... ).filter(search=SearchQuery("œuf", config="french"))
[<Entry: Pain perdu>]
```

The value of `config` could also be stored in another column:

```
>>> from django.db.models import F
>>> Entry.objects.annotate(
...     search=SearchVector("body_text", config=F("blog__language")),
... ).filter(search=SearchQuery("œuf", config=F("blog__language")))
[<Entry: Pain perdu>]
```

Weighting queries

Every field may not have the same relevance in a query, so you can set weights of various vectors before you combine them:

```
>>> from django.contrib.postgres.search import SearchQuery, SearchRank, SearchVector
>>> vector = SearchVector("body_text", weight="A") + SearchVector(
...     "blog__tagline", weight="B"
... )
>>> query = SearchQuery("cheese")
>>> Entry.objects.annotate(rank=SearchRank(vector, query)).filter(rank__gte=0.3).order_by(
...     "rank"
... )
```

The weight should be one of the following letters: D, C, B, A. By default, these weights refer to the numbers 0.1, 0.2, 0.4, and 1.0, respectively. If you wish to weight them differently, pass a list of four floats to *SearchRank* as weights in the same order above:

```
>>> rank = SearchRank(vector, query, weights=[0.2, 0.4, 0.6, 0.8])
>>> Entry.objects.annotate(rank=rank).filter(rank__gte=0.3).order_by("-rank")
```

Performance

Special database configuration isn't necessary to use any of these functions, however, if you're searching more than a few hundred records, you're likely to run into performance problems. Full text search is a more intensive process than comparing the size of an integer, for example.

In the event that all the fields you're querying on are contained within one particular model, you can create a functional *GIN* or *GIST* index which matches the search vector you wish to use. For example:

```
GinIndex(
    SearchVector("body_text", "headline", config="english"),
    name="search_vector_idx",
)
```

The PostgreSQL documentation has details on [creating indexes for full text search](#).

SearchVectorField

```
class SearchVectorField
```

If this approach becomes too slow, you can add a `SearchVectorField` to your model. You'll need to keep it populated with triggers, for example, as described in the [PostgreSQL documentation](#). You can then query the field as if it were an annotated `SearchVector`:

```
>>> Entry.objects.update(search_vector=SearchVector("body_text"))
>>> Entry.objects.filter(search_vector="cheese")
[<Entry: Cheese on Toast recipes>, <Entry: Pizza recipes>]
```

Trigram similarity

Another approach to searching is trigram similarity. A trigram is a group of three consecutive characters. In addition to the *trigram_similar*, *trigram_word_similar*, and *trigram_strict_word_similar* lookups, you can use a couple of other expressions.

To use them, you need to activate the [pg_trgm extension](#) on PostgreSQL. You can install it using the *TrigramExtension* migration operation.

TrigramSimilarity

```
class TrigramSimilarity(expression, string, **extra)
```

Accepts a field name or expression, and a string or expression. Returns the trigram similarity between the two arguments.

Usage example:

```
>>> from django.contrib.postgres.search import TrigramSimilarity
>>> Author.objects.create(name="Katy Stevens")
>>> Author.objects.create(name="Stephen Keats")
>>> test = "Katie Stephens"
>>> Author.objects.annotate(
...     similarity=TrigramSimilarity("name", test),
... ).filter(
...     similarity__gt=0.3
... ).order_by("-similarity")
[<Author: Katy Stevens>, <Author: Stephen Keats>]
```

TrigramWordSimilarity

```
class TrigramWordSimilarity(string, expression, **extra)
```

Accepts a string or expression, and a field name or expression. Returns the trigram word similarity between the two arguments.

Usage example:

```
>>> from django.contrib.postgres.search import TrigramWordSimilarity
>>> Author.objects.create(name="Katy Stevens")
>>> Author.objects.create(name="Stephen Keats")
>>> test = "Kat"
>>> Author.objects.annotate(
...     similarity=TrigramWordSimilarity(test, "name"),
... ).filter(
...     similarity__gt=0.3
... ).order_by("-similarity")
[<Author: Katy Stevens>]
```

TrigramStrictWordSimilarity

```
class TrigramStrictWordSimilarity(string, expression, **extra)
```

Accepts a string or expression, and a field name or expression. Returns the trigram strict word similarity between the two arguments. Similar to *TrigramWordSimilarity()*, except that it forces extent boundaries to match word boundaries.

TrigramDistance

```
class TrigramDistance(expression, string, **extra)
```

Accepts a field name or expression, and a string or expression. Returns the trigram distance between the two arguments.

Usage example:

```
>>> from django.contrib.postgres.search import TrigramDistance
>>> Author.objects.create(name="Katy Stevens")
>>> Author.objects.create(name="Stephen Keats")
>>> test = "Katie Stephens"
>>> Author.objects.annotate(
...     distance=TrigramDistance("name", test),
... ).filter(
```

(continues on next page)

(continued from previous page)

```
...     distance__lte=0.7
... ).order_by("distance")
[<Author: Katy Stevens>, <Author: Stephen Keats>]
```

TrigramWordDistance

```
class TrigramWordDistance(string, expression, **extra)
```

Accepts a string or expression, and a field name or expression. Returns the trigram word distance between the two arguments.

Usage example:

```
>>> from django.contrib.postgres.search import TrigramWordDistance
>>> Author.objects.create(name="Katy Stevens")
>>> Author.objects.create(name="Stephen Keats")
>>> test = "Kat"
>>> Author.objects.annotate(
...     distance=TrigramWordDistance(test, "name"),
... ).filter(
...     distance__lte=0.7
... ).order_by("distance")
[<Author: Katy Stevens>]
```

TrigramStrictWordDistance

```
class TrigramStrictWordDistance(string, expression, **extra)
```

Accepts a string or expression, and a field name or expression. Returns the trigram strict word distance between the two arguments.

Validators

These validators are available from the `django.contrib.postgres.validators` module.

KeysValidator

```
class KeysValidator(keys, strict=False, messages=None)
```

Validates that the given keys are contained in the value. If `strict` is `True`, then it also checks that there are no other keys present.

The `messages` passed should be a dict containing the keys `missing_keys` and/or `extra_keys`.

Note: Note that this checks only for the existence of a given key, not that the value of a key is non-empty.

Range validators

RangeMaxValueValidator

```
class RangeMaxValueValidator(limit_value, message=None)
```

Validates that the upper bound of the range is not greater than `limit_value`.

RangeMinValueValidator

```
class RangeMinValueValidator(limit_value, message=None)
```

Validates that the lower bound of the range is not less than the `limit_value`.

6.5.9 The redirects app

Django comes with an optional redirects application. It lets you store redirects in a database and handles the redirecting for you. It uses the HTTP response status code 301 `Moved Permanently` by default.

Installation

To install the redirects app, follow these steps:

1. Ensure that the `django.contrib.sites` framework is installed.
2. Add `'django.contrib.redirects'` to your `INSTALLED_APPS` setting.
3. Add `'django.contrib.redirects.middleware.RedirectFallbackMiddleware'` to your `MIDDLEWARE` setting.
4. Run the command `manage.py migrate`.

How it works

`manage.py migrate` creates a `django_redirect` table in your database. This is a lookup table with `site_id`, `old_path` and `new_path` fields.

The *`RedirectFallbackMiddleware`* does all of the work. Each time any Django application raises a 404 error, this middleware checks the redirects database for the requested URL as a last resort. Specifically, it checks for a redirect with the given `old_path` with a site ID that corresponds to the *`SITE_ID`* setting.

- If it finds a match, and `new_path` is not empty, it redirects to `new_path` using a 301 (“Moved Permanently”) redirect. You can subclass *`RedirectFallbackMiddleware`* and set *`response_redirect_class`* to *`django.http.HttpResponseRedirect`* to use a 302 Moved Temporarily redirect instead.
- If it finds a match, and `new_path` is empty, it sends a 410 (“Gone”) HTTP header and empty (contentless) response.
- If it doesn’t find a match, the request continues to be processed as usual.

The middleware only gets activated for 404s –not for 500s or responses of any other status code.

Note that the order of *`MIDDLEWARE`* matters. Generally, you can put *`RedirectFallbackMiddleware`* at the end of the list, because it’s a last resort.

For more on middleware, read the [middleware docs](#).

How to add, change and delete redirects

Via the admin interface

If you’ve activated the automatic Django admin interface, you should see a “Redirects” section on the admin index page. Edit redirects as you edit any other object in the system.

Via the Python API

```
class models.Redirect
```

Redirects are represented by a standard Django model, which lives in `django/contrib/redirects/models.py`. You can access redirect objects via the Django database API. For example:

```
>>> from django.conf import settings
>>> from django.contrib.redirects.models import Redirect
>>> # Add a new redirect.
>>> redirect = Redirect.objects.create(
...     site_id=1,
...     old_path="/contact-us/",
```

(continues on next page)

(continued from previous page)

```

...     new_path="/contact/",
... )
>>> # Change a redirect.
>>> redirect.new_path = "/contact-details/"
>>> redirect.save()
>>> redirect
<Redirect: /contact-us/ ---> /contact-details/>
>>> # Delete a redirect.
>>> Redirect.objects.filter(site_id=1, old_path="/contact-us/").delete()
(1, {'redirects.Redirect': 1})

```

Middleware

class middleware.RedirectFallbackMiddleware

You can change the *HttpResponse* classes used by the middleware by creating a subclass of *RedirectFallbackMiddleware* and overriding `response_gone_class` and/or `response_redirect_class`.

response_gone_class

The *HttpResponse* class used when a *Redirect* is not found for the requested path or has a blank `new_path` value.

Defaults to *HttpResponseGone*.

response_redirect_class

The *HttpResponse* class that handles the redirect.

Defaults to *HttpResponsePermanentRedirect*.

6.5.10 The sitemap framework

Django comes with a high-level sitemap-generating framework to create *sitemap* XML files.

Overview

A sitemap is an XML file on your website that tells search-engine indexers how frequently your pages change and how “important” certain pages are in relation to other pages on your site. This information helps search engines index your site.

The Django sitemap framework automates the creation of this XML file by letting you express this information in Python code.

It works much like Django’s *syndication framework*. To create a sitemap, write a *Sitemap* class and point to it in your *URLconf*.

Installation

To install the sitemap app, follow these steps:

1. Add 'django.contrib.sitemaps' to your *INSTALLED_APPS* setting.
2. Make sure your *TEMPLATES* setting contains a DjangoTemplates backend whose APP_DIRS options is set to True. It's in there by default, so you'll only need to change this if you've changed that setting.
3. Make sure you've installed the *sites framework*.

(Note: The sitemap application doesn't install any database tables. The only reason it needs to go into *INSTALLED_APPS* is so that the *Loader()* template loader can find the default templates.)

Initialization

```
views.sitemap(request, sitemaps, section=None, template_name='sitemap.xml',
               content_type='application/xml')
```

To activate sitemap generation on your Django site, add this line to your *URLconf*:

```
from django.contrib.sitemaps.views import sitemap

path(
    "sitemap.xml",
    sitemap,
    {"sitemaps": sitemaps},
    name="django.contrib.sitemaps.views.sitemap",
)
```

This tells Django to build a sitemap when a client accesses */sitemap.xml*.

The name of the sitemap file is not important, but the location is. Search engines will only index links in your sitemap for the current URL level and below. For instance, if *sitemap.xml* lives in your root directory, it may reference any URL in your site. However, if your sitemap lives at */content/sitemap.xml*, it may only reference URLs that begin with */content/*.

The sitemap view takes an extra, required argument: {'sitemaps': sitemaps}. sitemaps should be a dictionary that maps a short section label (e.g., *blog* or *news*) to its *Sitemap* class (e.g., *BlogSitemap* or *NewsSitemap*). It may also map to an instance of a *Sitemap* class (e.g., *BlogSitemap(some_var)*).

Sitemap classes

A *Sitemap* class is a Python class that represents a “section” of entries in your sitemap. For example, one *Sitemap* class could represent all the entries of your blog, while another could represent all of the events in your events calendar.

In the simplest case, all these sections get lumped together into one `sitemap.xml`, but it’s also possible to use the framework to generate a sitemap index that references individual sitemap files, one per section. (See [Creating a sitemap index](#) below.)

Sitemap classes must subclass `django.contrib.sitemaps.Sitemap`. They can live anywhere in your code-base.

An example

Let’s assume you have a blog system, with an `Entry` model, and you want your sitemap to include all the links to your individual blog entries. Here’s how your sitemap class might look:

```
from django.contrib.sitemaps import Sitemap
from blog.models import Entry

class BlogSitemap(Sitemap):
    changefreq = "never"
    priority = 0.5

    def items(self):
        return Entry.objects.filter(is_draft=False)

    def lastmod(self, obj):
        return obj.pub_date
```

Note:

- *changefreq* and *priority* are class attributes corresponding to `<changefreq>` and `<priority>` elements, respectively. They can be made callable as functions, as *lastmod* was in the example.
- *items()* is a method that returns a [sequence](#) or `QuerySet` of objects. The objects returned will get passed to any callable methods corresponding to a sitemap property (*location*, *lastmod*, *changefreq*, and *priority*).
- *lastmod* should return a `datetime`.
- There is no *location* method in this example, but you can provide it in order to specify the URL for your object. By default, *location()* calls `get_absolute_url()` on each object and returns the result.

Sitemap class reference

class Sitemap

A Sitemap class can define the following methods/attributes:

items

Required. A method that returns a [sequence](#) or `QuerySet` of objects. The framework doesn't care what type of objects they are; all that matters is that these objects get passed to the `location()`, `lastmod()`, `changefreq()` and `priority()` methods.

location

Optional. Either a method or attribute.

If it's a method, it should return the absolute path for a given object as returned by `items()`.

If it's an attribute, its value should be a string representing an absolute path to use for every object returned by `items()`.

In both cases, “absolute path” means a URL that doesn't include the protocol or domain. Examples:

- Good: `'/foo/bar/'`
- Bad: `'example.com/foo/bar/'`
- Bad: `'https://example.com/foo/bar/'`

If `location` isn't provided, the framework will call the `get_absolute_url()` method on each object as returned by `items()`.

To specify a protocol other than `'http'`, use `protocol`.

lastmod

Optional. Either a method or attribute.

If it's a method, it should take one argument—an object as returned by `items()`—and return that object's last-modified date/time as a `datetime`.

If it's an attribute, its value should be a `datetime` representing the last-modified date/time for every object returned by `items()`.

If all items in a sitemap have a `lastmod`, the sitemap generated by `views.sitemap()` will have a Last-Modified header equal to the latest `lastmod`. You can activate the `ConditionalGetMiddleware` to make Django respond appropriately to requests with an If-Modified-Since header which will prevent sending the sitemap if it hasn't changed.

paginator

Optional.

This property returns a `Paginator` for `items()`. If you generate sitemaps in a batch you may want to override this as a cached property in order to avoid multiple `items()` calls.

changefreq

Optional. Either a method or attribute.

If it's a method, it should take one argument –an object as returned by `items()` –and return that object's change frequency as a string.

If it's an attribute, its value should be a string representing the change frequency of every object returned by `items()`.

Possible values for `changefreq`, whether you use a method or attribute, are:

- 'always'
- 'hourly'
- 'daily'
- 'weekly'
- 'monthly'
- 'yearly'
- 'never'

priority

Optional. Either a method or attribute.

If it's a method, it should take one argument –an object as returned by `items()` –and return that object's priority as either a string or float.

If it's an attribute, its value should be either a string or float representing the priority of every object returned by `items()`.

Example values for `priority`: 0.4, 1.0. The default priority of a page is 0.5. See the [sitemaps.org documentation](https://www.sitemaps.org/documentation) for more.

protocol

Optional.

This attribute defines the protocol ('http' or 'https') of the URLs in the sitemap. If it isn't set, the protocol with which the sitemap was requested is used. If the sitemap is built outside the context of a request, the default is 'http'.

Deprecated since version 4.0: The default protocol for sitemaps built outside the context of a request will change from 'http' to 'https' in Django 5.0.

limit

Optional.

This attribute defines the maximum number of URLs included on each page of the sitemap. Its value should not exceed the default value of 50000, which is the upper limit allowed in the [Sitemaps protocol](https://www.sitemaps.org).

`i18n`

Optional.

A boolean attribute that defines if the URLs of this sitemap should be generated using all of your *LANGUAGES*. The default is `False`.

`languages`

Optional.

A sequence of language codes to use for generating alternate links when *i18n* is enabled. Defaults to *LANGUAGES*.

`alternates`

Optional.

A boolean attribute. When used in conjunction with *i18n* generated URLs will each have a list of alternate links pointing to other language versions using the *hreflang* attribute. The default is `False`.

`x_default`

Optional.

A boolean attribute. When `True` the alternate links generated by *alternates* will contain a *hreflang*="x-default" fallback entry with a value of *LANGUAGE_CODE*. The default is `False`.

`get_latest_lastmod()`

Optional. A method that returns the latest value returned by *lastmod*. This function is used to add the *lastmod* attribute to Sitemap index context variables.

By default *get_latest_lastmod()* returns:

- If *lastmod* is an attribute: *lastmod*.
- If *lastmod* is a method: The latest *lastmod* returned by calling the method with all items returned by *Sitemap.items()*.

`get_languages_for_item(item)`

Optional. A method that returns the sequence of language codes for which the item is displayed.

By default *get_languages_for_item()* returns *languages*.

Shortcuts

The sitemap framework provides a convenience class for a common case:

```
class GenericSitemap(info_dict, priority=None, changefreq=None, protocol=None)
```

The *django.contrib.sitemaps.GenericSitemap* class allows you to create a sitemap by passing it a dictionary which has to contain at least a *queryset* entry. This *queryset* will be used to generate the items of the sitemap. It may also have a *date_field* entry that specifies a date field for objects retrieved

from the `queryset`. This will be used for the `lastmod` attribute and `get_latest_lastmod()` methods in the in the generated sitemap.

The `priority`, `changefreq`, and `protocol` keyword arguments allow specifying these attributes for all URLs.

Example

Here's an example of a `URLconf` using `GenericSitemap`:

```
from django.contrib.sitemaps import GenericSitemap
from django.contrib.sitemaps.views import sitemap
from django.urls import path
from blog.models import Entry

info_dict = {
    "queryset": Entry.objects.all(),
    "date_field": "pub_date",
}

urlpatterns = [
    # some generic view using info_dict
    # ...
    # the sitemap
    path(
        "sitemap.xml",
        sitemap,
        {"sitemaps": {"blog": GenericSitemap(info_dict, priority=0.6)}},
        name="django.contrib.sitemaps.views.sitemap",
    ),
]
```

Sitemap for static views

Often you want the search engine crawlers to index views which are neither object detail pages nor flatpages. The solution is to explicitly list URL names for these views in `items` and call `reverse()` in the `location` method of the `sitemap`. For example:

```
# sitemaps.py
from django.contrib import sitemaps
from django.urls import reverse
```

(continues on next page)

(continued from previous page)

```
class StaticViewSitemap(sitemaps.Sitemap):
    priority = 0.5
    changefreq = "daily"

    def items(self):
        return ["main", "about", "license"]

    def location(self, item):
        return reverse(item)

# urls.py
from django.contrib.sitemaps.views import sitemap
from django.urls import path

from .sitemaps import StaticViewSitemap
from . import views

sitemaps = {
    "static": StaticViewSitemap,
}

urlpatterns = [
    path("", views.main, name="main"),
    path("about/", views.about, name="about"),
    path("license/", views.license, name="license"),
    # ...
    path(
        "sitemap.xml",
        sitemap,
        {"sitemaps": sitemaps},
        name="django.contrib.sitemaps.views.sitemap",
    ),
]
```

Creating a sitemap index

```
views.index(request, sitemaps, template_name='sitemap_index.xml', content_type='application/xml',
            sitemap_url_name='django.contrib.sitemaps.views.sitemap')
```

The sitemap framework also has the ability to create a sitemap index that references individual sitemap files, one per each section defined in your `sitemaps` dictionary. The only differences in usage are:

- You use two views in your URLconf: `django.contrib.sitemaps.views.index()` and `django.`

`contrib.sitemaps.views.sitemap()`.

- The `django.contrib.sitemaps.views.sitemap()` view should take a `section` keyword argument.

Here's what the relevant URLconf lines would look like for the example above:

```
from django.contrib.sitemaps import views

urlpatterns = [
    path(
        "sitemap.xml",
        views.index,
        {"sitemaps": sitemaps},
        name="django.contrib.sitemaps.views.index",
    ),
    path(
        "sitemap-<section>.xml",
        views.sitemap,
        {"sitemaps": sitemaps},
        name="django.contrib.sitemaps.views.sitemap",
    ),
]
```

This will automatically generate a `sitemap.xml` file that references both `sitemap-flatpages.xml` and `sitemap-blog.xml`. The `Sitemap` classes and the `sitemaps` dict don't change at all.

If all sitemaps have a `lastmod` returned by `Sitemap.get_latest_lastmod()` the sitemap index will have a Last-Modified header equal to the latest `lastmod`.

You should create an index file if one of your sitemaps has more than 50,000 URLs. In this case, Django will automatically paginate the sitemap, and the index will reflect that.

If you're not using the vanilla sitemap view—for example, if it's wrapped with a caching decorator—you must name your sitemap view and pass `sitemap_url_name` to the index view:

```
from django.contrib.sitemaps import views as sitemaps_views
from django.views.decorators.cache import cache_page

urlpatterns = [
    path(
        "sitemap.xml",
        cache_page(86400)(sitemaps_views.index),
        {"sitemaps": sitemaps, "sitemap_url_name": "sitemaps"},
    ),
    path(
        "sitemap-<section>.xml",
        cache_page(86400)(sitemaps_views.sitemap),
    ),
]
```

(continues on next page)

(continued from previous page)

```
        {"sitemaps": sitemaps},
        name="sitemaps",
    ),
]
```

Use of the `Last-Modified` header was added.

Template customization

If you wish to use a different template for each sitemap or sitemap index available on your site, you may specify it by passing a `template_name` parameter to the `sitemap` and `index` views via the `URLconf`:

```
from django.contrib.sitemaps import views

urlpatterns = [
    path(
        "custom-sitemap.xml",
        views.index,
        {"sitemaps": sitemaps, "template_name": "custom_sitemap.html"},
        name="django.contrib.sitemaps.views.index",
    ),
    path(
        "custom-sitemap-<section>.xml",
        views.sitemap,
        {"sitemaps": sitemaps, "template_name": "custom_sitemap.html"},
        name="django.contrib.sitemaps.views.sitemap",
    ),
]
```

These views return *TemplateResponse* instances which allow you to easily customize the response data before rendering. For more details, see the [TemplateResponse documentation](#).

Context variables

When customizing the templates for the `index()` and `sitemap()` views, you can rely on the following context variables.

Index

The variable `sitemaps` is a list of objects containing the `location` and `lastmod` attribute for each of the sitemaps. Each URL exposes the following attributes:

- `location`: The location (url & page) of the sitemap.
- `lastmod`: Populated by the `get_latest_lastmod()` method for each sitemap.

The context was changed to a list of objects with `location` and optional `lastmod` attributes.

Sitemap

The variable `urlset` is a list of URLs that should appear in the sitemap. Each URL exposes attributes as defined in the `Sitemap` class:

- `alternates`
- `changefreq`
- `item`
- `lastmod`
- `location`
- `priority`

The `alternates` attribute is available when `118n` and `alternates` are enabled. It is a list of other language versions, including the optional `x_default` fallback, for each URL. Each alternate is a dictionary with `location` and `lang_code` keys.

The `item` attribute has been added for each URL to allow more flexible customization of the templates, such as Google news sitemaps. Assuming Sitemap's `items()` would return a list of items with `publication_data` and a `tags` field something like this would generate a Google News compatible sitemap:

```
<?xml version="1.0" encoding="UTF-8"?>
<urlset
  xmlns="https://www.sitemaps.org/schemas/sitemap/0.9"
  xmlns:news="http://www.google.com/schemas/sitemap-news/0.9">
  {% spaceless %}
  {% for url in urlset %}
    <url>
```

(continues on next page)

(continued from previous page)

```
<loc>{{ url.location }}</loc>
{% if url.lastmod %}<lastmod>{{ url.lastmod|date:"Y-m-d" }}</lastmod>{% endif %}
{% if url.changefreq %}<changefreq>{{ url.changefreq }}</changefreq>{% endif %}
{% if url.priority %}<priority>{{ url.priority }}</priority>{% endif %}
<news:news>
    {% if url.item.publication_date %}<news:publication_date>{{ url.item.publication_date|date:
↪"Y-m-d" }}</news:publication_date>{% endif %}
    {% if url.item.tags %}<news:keywords>{{ url.item.tags }}</news:keywords>{% endif %}
</news:news>
</url>
{% endfor %}
{% endspaceless %}
</urlset>
```

Pinging Google

You may want to “ping” Google when your sitemap changes, to let it know to reindex your site. The sitemaps framework provides a function to do just that: `django.contrib.sitemaps.ping_google()`.

`ping_google(sitemap_url=None, ping_url=PING_URL, sitemap_uses_https=True)`

`ping_google` takes these optional arguments:

- `sitemap_url` - The absolute path to your site’s sitemap (e.g., `‘/sitemap.xml’`).
If this argument isn’t provided, `ping_google` will perform a reverse lookup in your URL-conf, for URLs named `‘django.contrib.sitemaps.views.index’` and then `‘django.contrib.sitemaps.views.sitemap’` (without further arguments) to automatically determine the sitemap URL.
- `ping_url` - Defaults to Google’s Ping Tool: <https://www.google.com/webmasters/tools/ping>.
- `sitemap_uses_https` - Set to `False` if your site uses `http` rather than `https`.

`ping_google()` raises the exception `django.contrib.sitemaps.SitemapNotFound` if it cannot determine your sitemap URL.

Register with Google first!

The `ping_google()` command only works if you have registered your site with [Google Search Console](#).

One useful way to call `ping_google()` is from a model’s `save()` method:

```
from django.contrib.sitemaps import ping_google
```

(continues on next page)

(continued from previous page)

```
class Entry(models.Model):
    # ...
    def save(self, force_insert=False, force_update=False):
        super().save(force_insert, force_update)
        try:
            ping_google()
        except Exception:
            # Bare 'except' because we could get a variety
            # of HTTP-related exceptions.
        pass
```

A more efficient solution, however, would be to call `ping_google()` from a cron script, or some other scheduled task. The function makes an HTTP request to Google’s servers, so you may not want to introduce that network overhead each time you call `save()`.

Pinging Google via `manage.py`

```
django-admin ping_google [sitemap_url]
```

Once the sitemaps application is added to your project, you may also ping Google using the `ping_google` management command:

```
python manage.py ping_google [/sitemap.xml]
```

--sitemap-uses-http

Use this option if your sitemap uses `http` rather than `https`.

6.5.11 The “sites” framework

Django comes with an optional “sites” framework. It’s a hook for associating objects and functionality to particular websites, and it’s a holding place for the domain names and “verbose” names of your Django-powered sites.

Use it if your single Django installation powers more than one site and you need to differentiate between those sites in some way.

The sites framework is mainly based on this model:

```
class models.Site
```

A model for storing the domain and name attributes of a website.

domain

The fully qualified domain name associated with the website. For example, `www.example.com`.

name

A human-readable “verbose” name for the website.

The `SITE_ID` setting specifies the database ID of the `Site` object associated with that particular settings file. If the setting is omitted, the `get_current_site()` function will try to get the current site by comparing the `domain` with the host name from the `request.get_host()` method.

How you use this is up to you, but Django uses it in a couple of ways automatically via a couple of conventions.

Example usage

Why would you use sites? It’s best explained through examples.

Associating content with multiple sites

The `LJWorld.com` and `Lawrence.com` sites are operated by the same news organization –the Lawrence Journal-World newspaper in Lawrence, Kansas. `LJWorld.com` focused on news, while `Lawrence.com` focused on local entertainment. But sometimes editors wanted to publish an article on both sites.

The naive way of solving the problem would be to require site producers to publish the same story twice: once for `LJWorld.com` and again for `Lawrence.com`. But that’s inefficient for site producers, and it’s redundant to store multiple copies of the same story in the database.

A better solution removes the content duplication: Both sites use the same article database, and an article is associated with one or more sites. In Django model terminology, that’s represented by a `ManyToManyField` in the `Article` model:

```
from django.contrib.sites.models import Site
from django.db import models

class Article(models.Model):
    headline = models.CharField(max_length=200)
    # ...
    sites = models.ManyToManyField(Site)
```

This accomplishes several things quite nicely:

- It lets the site producers edit all content –on both sites –in a single interface (the Django admin).
- It means the same story doesn’t have to be published twice in the database; it only has a single record in the database.

- It lets the site developers use the same Django view code for both sites. The view code that displays a given story checks to make sure the requested story is on the current site. It looks something like this:

```
from django.contrib.sites.shortcuts import get_current_site

def article_detail(request, article_id):
    try:
        a = Article.objects.get(id=article_id, sites__id=get_current_site(request).id)
    except Article.DoesNotExist:
        raise Http404("Article does not exist on this site")
    # ...
```

Associating content with a single site

Similarly, you can associate a model to the *Site* model in a many-to-one relationship, using *ForeignKey*.

For example, if an article is only allowed on a single site, you'd use a model like this:

```
from django.contrib.sites.models import Site
from django.db import models

class Article(models.Model):
    headline = models.CharField(max_length=200)
    # ...
    site = models.ForeignKey(Site, on_delete=models.CASCADE)
```

This has the same benefits as described in the last section.

Hooking into the current site from views

You can use the sites framework in your Django views to do particular things based on the site in which the view is being called. For example:

```
from django.conf import settings

def my_view(request):
    if settings.SITE_ID == 3:
        # Do something.
        pass
    else:
```

(continues on next page)

(continued from previous page)

```
# Do something else.
pass
```

It's fragile to hard-code the site IDs like that, in case they change. The cleaner way of accomplishing the same thing is to check the current site's domain:

```
from django.contrib.sites.shortcuts import get_current_site

def my_view(request):
    current_site = get_current_site(request)
    if current_site.domain == "foo.com":
        # Do something
        pass
    else:
        # Do something else.
        pass
```

This has also the advantage of checking if the sites framework is installed, and return a *RequestSite* instance if it is not.

If you don't have access to the request object, you can use the `get_current()` method of the *Site* model's manager. You should then ensure that your settings file does contain the *SITE_ID* setting. This example is equivalent to the previous one:

```
from django.contrib.sites.models import Site

def my_function_without_request():
    current_site = Site.objects.get_current()
    if current_site.domain == "foo.com":
        # Do something
        pass
    else:
        # Do something else.
        pass
```

Getting the current domain for display

LJWorld.com and Lawrence.com both have email alert functionality, which lets readers sign up to get notifications when news happens. It's pretty basic: A reader signs up on a web form and immediately gets an email saying, "Thanks for your subscription."

It'd be inefficient and redundant to implement this sign up processing code twice, so the sites use the same code behind the scenes. But the "thank you for signing up" notice needs to be different for each site. By using *Site* objects, we can abstract the "thank you" notice to use the values of the current site's *name* and *domain*.

Here's an example of what the form-handling view looks like:

```
from django.contrib.sites.shortcuts import get_current_site
from django.core.mail import send_mail

def register_for_newsletter(request):
    # Check form values, etc., and subscribe the user.
    # ...

    current_site = get_current_site(request)
    send_mail(
        "Thanks for subscribing to %s alerts" % current_site.name,
        "Thanks for your subscription. We appreciate it.\n\n-The %s team."
        % (current_site.name,),
        "editor@%s" % current_site.domain,
        [user.email],
    )

    # ...
```

On Lawrence.com, this email has the subject line "Thanks for subscribing to lawrence.com alerts." On LJWorld.com, the email has the subject "Thanks for subscribing to LJWorld.com alerts." Same goes for the email's message body.

Note that an even more flexible (but more heavyweight) way of doing this would be to use Django's template system. Assuming Lawrence.com and LJWorld.com have different template directories (*DIRS*), you could farm out to the template system like so:

```
from django.core.mail import send_mail
from django.template import loader

def register_for_newsletter(request):
```

(continues on next page)

(continued from previous page)

```
# Check form values, etc., and subscribe the user.
# ...

subject = loader.get_template("alerts/subject.txt").render({})
message = loader.get_template("alerts/message.txt").render({})
send_mail(subject, message, "editor@ljworld.com", [user.email])

# ...
```

In this case, you'd have to create `subject.txt` and `message.txt` template files for both the LJWorld.com and Lawrence.com template directories. That gives you more flexibility, but it's also more complex.

It's a good idea to exploit the `Site` objects as much as possible, to remove unneeded complexity and redundancy.

Getting the current domain for full URLs

Django's `get_absolute_url()` convention is nice for getting your objects' URL without the domain name, but in some cases you might want to display the full URL –with `http://` and the domain and everything – for an object. To do this, you can use the sites framework. An example:

```
>>> from django.contrib.sites.models import Site
>>> obj = MyModel.objects.get(id=3)
>>> obj.get_absolute_url()
'/mymodel/objects/3/'
>>> Site.objects.get_current().domain
'example.com'
>>> "https://%s%s" % (Site.objects.get_current().domain, obj.get_absolute_url())
'https://example.com/mymodel/objects/3/'
```

Enabling the sites framework

To enable the sites framework, follow these steps:

1. Add `'django.contrib.sites'` to your `INSTALLED_APPS` setting.
2. Define a `SITE_ID` setting:

```
SITE_ID = 1
```

3. Run `migrate`.

`django.contrib.sites` registers a `post_migrate` signal handler which creates a default site named `example.com` with the domain `example.com`. This site will also be created after Django creates the test

database. To set the correct name and domain for your project, you can use a [data migration](#).

In order to serve different sites in production, you'd create a separate settings file with each `SITE_ID` (perhaps importing from a common settings file to avoid duplicating shared settings) and then specify the appropriate `DJANGO_SETTINGS_MODULE` for each site.

Caching the current Site object

As the current site is stored in the database, each call to `Site.objects.get_current()` could result in a database query. But Django is a little cleverer than that: on the first request, the current site is cached, and any subsequent call returns the cached data instead of hitting the database.

If for any reason you want to force a database query, you can tell Django to clear the cache using `Site.objects.clear_cache()`:

```
# First call; current site fetched from database.
current_site = Site.objects.get_current()
# ...

# Second call; current site fetched from cache.
current_site = Site.objects.get_current()
# ...

# Force a database query for the third call.
Site.objects.clear_cache()
current_site = Site.objects.get_current()
```

The CurrentSiteManager

```
class managers.CurrentSiteManager
```

If `Site` plays a key role in your application, consider using the helpful `CurrentSiteManager` in your model(s). It's a model [manager](#) that automatically filters its queries to include only objects associated with the current `Site`.

Mandatory `SITE_ID`

The `CurrentSiteManager` is only usable when the `SITE_ID` setting is defined in your settings.

Use `CurrentSiteManager` by adding it to your model explicitly. For example:

```
from django.contrib.sites.models import Site
from django.contrib.sites.managers import CurrentSiteManager
```

(continues on next page)

(continued from previous page)

```
from django.db import models

class Photo(models.Model):
    photo = models.FileField(upload_to="photos")
    photographer_name = models.CharField(max_length=100)
    pub_date = models.DateField()
    site = models.ForeignKey(Site, on_delete=models.CASCADE)
    objects = models.Manager()
    on_site = CurrentSiteManager()
```

With this model, `Photo.objects.all()` will return all `Photo` objects in the database, but `Photo.on_site.all()` will return only the `Photo` objects associated with the current site, according to the `SITE_ID` setting.

Put another way, these two statements are equivalent:

```
Photo.objects.filter(site=settings.SITE_ID)
Photo.on_site.all()
```

How did `CurrentSiteManager` know which field of `Photo` was the `Site`? By default, `CurrentSiteManager` looks for either a `ForeignKey` called `site` or a `ManyToManyField` called `sites` to filter on. If you use a field named something other than `site` or `sites` to identify which `Site` objects your object is related to, then you need to explicitly pass the custom field name as a parameter to `CurrentSiteManager` on your model. The following model, which has a field called `publish_on`, demonstrates this:

```
from django.contrib.sites.models import Site
from django.contrib.sites.managers import CurrentSiteManager
from django.db import models

class Photo(models.Model):
    photo = models.FileField(upload_to="photos")
    photographer_name = models.CharField(max_length=100)
    pub_date = models.DateField()
    publish_on = models.ForeignKey(Site, on_delete=models.CASCADE)
    objects = models.Manager()
    on_site = CurrentSiteManager("publish_on")
```

If you attempt to use `CurrentSiteManager` and pass a field name that doesn't exist, Django will raise a `ValueError`.

Finally, note that you'll probably want to keep a normal (non-site-specific) `Manager` on your model, even if you use `CurrentSiteManager`. As explained in the [manager documentation](#), if you define a manager manually, then Django won't create the automatic `objects = models.Manager()` manager for you. Also note that certain parts of Django—namely, the Django admin site and generic views—use whichever manager is

defined first in the model, so if you want your admin site to have access to all objects (not just site-specific ones), put `objects = models.Manager()` in your model, before you define `CurrentSiteManager`.

Site middleware

If you often use this pattern:

```
from django.contrib.sites.models import Site

def my_view(request):
    site = Site.objects.get_current()
    ...
```

To avoid repetitions, add `django.contrib.sites.middleware.CurrentSiteMiddleware` to `MIDDLEWARE`. The middleware sets the `site` attribute on every request object, so you can use `request.site` to get the current site.

How Django uses the sites framework

Although it's not required that you use the sites framework, it's strongly encouraged, because Django takes advantage of it in a few places. Even if your Django installation is powering only a single site, you should take the two seconds to create the site object with your domain and name, and point to its ID in your `SITE_ID` setting.

Here's how Django uses the sites framework:

- In the *redirects framework*, each redirect object is associated with a particular site. When Django searches for a redirect, it takes into account the current site.
- In the *flatpages framework*, each flatpage is associated with a particular site. When a flatpage is created, you specify its `Site`, and the `FlatpageFallbackMiddleware` checks the current site in retrieving flatpages to display.
- In the *syndication framework*, the templates for title and description automatically have access to a variable `{{ site }}`, which is the `Site` object representing the current site. Also, the hook for providing item URLs will use the domain from the current `Site` object if you don't specify a fully-qualified domain.
- In the *authentication framework*, `django.contrib.auth.views.LoginView` passes the current `Site` name to the template as `{{ site_name }}`.
- The shortcut view (`django.contrib.contenttypes.views.shortcut`) uses the domain of the current `Site` object when calculating an object's URL.
- In the admin framework, the “view on site” link uses the current `Site` to work out the domain for the site that it will redirect to.

RequestSite objects

Some `django.contrib` applications take advantage of the sites framework but are architected in a way that doesn't require the sites framework to be installed in your database. (Some people don't want to, or just aren't able to install the extra database table that the sites framework requires.) For those cases, the framework provides a `django.contrib.sites.requests.RequestSite` class, which can be used as a fallback when the database-backed sites framework is not available.

```
class requests.RequestSite
```

A class that shares the primary interface of `Site` (i.e., it has `domain` and `name` attributes) but gets its data from a Django `HttpRequest` object rather than from a database.

```
    __init__(request)
```

Sets the `name` and `domain` attributes to the value of `get_host()`.

A `RequestSite` object has a similar interface to a normal `Site` object, except its `__init__()` method takes an `HttpRequest` object. It's able to deduce the `domain` and `name` by looking at the request's domain. It has `save()` and `delete()` methods to match the interface of `Site`, but the methods raise `NotImplementedError`.

get_current_site shortcut

Finally, to avoid repetitive fallback code, the framework provides a `django.contrib.sites.shortcuts.get_current_site()` function.

```
shortcuts.get_current_site(request)
```

A function that checks if `django.contrib.sites` is installed and returns either the current `Site` object or a `RequestSite` object based on the request. It looks up the current site based on `request.get_host()` if the `SITE_ID` setting is not defined.

Both a domain and a port may be returned by `request.get_host()` when the Host header has a port explicitly specified, e.g. `example.com:80`. In such cases, if the lookup fails because the host does not match a record in the database, the port is stripped and the lookup is retried with the domain part only. This does not apply to `RequestSite` which will always use the unmodified host.

6.5.12 The staticfiles app

`django.contrib.staticfiles` collects static files from each of your applications (and any other places you specify) into a single location that can easily be served in production.

See also:

For an introduction to the static files app and some usage examples, see [How to manage static files](#) (e.g. images, JavaScript, CSS). For guidelines on deploying static files, see [How to deploy static files](#).

Settings

See [staticfiles settings](#) for details on the following settings:

- *STORAGES*
- *STATIC_ROOT*
- *STATIC_URL*
- *STATICFILES_DIRS*
- *STATICFILES_STORAGE*
- *STATICFILES_FINDERS*

Management Commands

`django.contrib.staticfiles` exposes three management commands.

`collectstatic`

`django-admin collectstatic`

Collects the static files into *STATIC_ROOT*.

Duplicate file names are by default resolved in a similar way to how template resolution works: the file that is first found in one of the specified locations will be used. If you're confused, the *findstatic* command can help show you which files are found.

On subsequent `collectstatic` runs (if *STATIC_ROOT* isn't empty), files are copied only if they have a modified timestamp greater than the timestamp of the file in *STATIC_ROOT*. Therefore if you remove an application from *INSTALLED_APPS*, it's a good idea to use the `collectstatic --clear` option in order to remove stale static files.

Files are searched by using the *enabled finders*. The default is to look in all locations defined in *STATICFILES_DIRS* and in the 'static' directory of apps specified by the *INSTALLED_APPS* setting.

The `collectstatic` management command calls the `post_process()` method of the `staticfiles` storage backend from *STORAGES* after each run and passes a list of paths that have been found by the management command. It also receives all command line options of `collectstatic`. This is used by the *ManifestStaticFilesStorage* by default.

By default, collected files receive permissions from *FILE_UPLOAD_PERMISSIONS* and collected directories receive permissions from *FILE_UPLOAD_DIRECTORY_PERMISSIONS*. If you would like different permissions for these files and/or directories, you can subclass either of the [static files storage classes](#) and specify the `file_permissions_mode` and/or `directory_permissions_mode` parameters, respectively. For example:

```
from django.contrib.staticfiles import storage

class MyStaticFilesStorage(storage.StaticFilesStorage):
    def __init__(self, *args, **kwargs):
        kwargs["file_permissions_mode"] = 0o640
        kwargs["directory_permissions_mode"] = 0o760
        super().__init__(*args, **kwargs)
```

Then set the `staticfiles` storage backend in `STORAGES` setting to `'path.to.MyStaticFilesStorage'`.

Some commonly used options are:

--noinput, --no-input

Do NOT prompt the user for input of any kind.

--ignore PATTERN, -i PATTERN

Ignore files, directories, or paths matching this glob-style pattern. Use multiple times to ignore more.

When specifying a path, always use forward slashes, even on Windows.

--dry-run, -n

Do everything except modify the filesystem.

--clear, -c

Clear the existing files before trying to copy or link the original file.

--link, -l

Create a symbolic link to each file instead of copying.

--no-post-process

Don't call the `post_process()` method of the configured `staticfiles` storage backend from `STORAGES`.

--no-default-ignore

Don't ignore the common private glob-style patterns `'CVS'`, `'*.'` and `'*~'`.

For a full list of options, refer to the commands own help by running:

```
$ python manage.py collectstatic --help
```

Customizing the ignored pattern list

The default ignored pattern list, `['CVS', '.*', '*~']`, can be customized in a more persistent way than providing the `--ignore` command option at each `collectstatic` invocation. Provide a custom `AppConfig` class, override the `ignore_patterns` attribute of this class and replace `'django.contrib.staticfiles'` with that class path in your `INSTALLED_APPS` setting:

```
from django.contrib.staticfiles.apps import StaticFilesConfig

class MyStaticFilesConfig(StaticFilesConfig):
    ignore_patterns = [...] # your custom ignore list
```

findstatic

`django-admin findstatic staticfile [staticfile ...]`

Searches for one or more relative paths with the enabled finders.

For example:

```
$ python manage.py findstatic css/base.css admin/js/core.js
Found 'css/base.css' here:
  /home/special.polls.com/core/static/css/base.css
  /home/polls.com/core/static/css/base.css
Found 'admin/js/core.js' here:
  /home/polls.com/src/django/contrib/admin/media/js/core.js
```

findstatic --first

By default, all matching locations are found. To only return the first match for each relative path, use the `--first` option:

```
$ python manage.py findstatic css/base.css --first
Found 'css/base.css' here:
  /home/special.polls.com/core/static/css/base.css
```

This is a debugging aid; it'll show you exactly which static file will be collected for a given path.

By setting the `--verbosity` flag to 0, you can suppress the extra output and just get the path names:

```
$ python manage.py findstatic css/base.css --verbosity 0
/home/special.polls.com/core/static/css/base.css
/home/polls.com/core/static/css/base.css
```

On the other hand, by setting the `--verbosity` flag to 2, you can get all the directories which were searched:

```
$ python manage.py findstatic css/base.css --verbosity 2
Found 'css/base.css' here:
  /home/special.polls.com/core/static/css/base.css
  /home/polls.com/core/static/css/base.css
Looking in the following locations:
  /home/special.polls.com/core/static
  /home/polls.com/core/static
  /some/other/path/static
```

`runserver`

`django-admin runserver [addrport]`

Overrides the core `runserver` command if the `staticfiles` app is *installed* and adds automatic serving of static files. File serving doesn't run through *MIDDLEWARE*.

The command adds these options:

`--nostatic`

Use the `--nostatic` option to disable serving of static files with the `staticfiles` app entirely. This option is only available if the `staticfiles` app is in your project's *INSTALLED_APPS* setting.

Example usage:

```
$ django-admin runserver --nostatic
```

`--insecure`

Use the `--insecure` option to force serving of static files with the `staticfiles` app even if the *DEBUG* setting is `False`. By using this you acknowledge the fact that it's grossly inefficient and probably insecure. This is only intended for local development, should never be used in production and is only available if the `staticfiles` app is in your project's *INSTALLED_APPS* setting.

`--insecure` doesn't work with *ManifestStaticFilesStorage*.

Example usage:

```
$ django-admin runserver --insecure
```

Storages

StaticFilesStorage

```
class storage.StaticFilesStorage
```

A subclass of the *FileSystemStorage* storage backend that uses the *STATIC_ROOT* setting as the base file system location and the *STATIC_URL* setting respectively as the base URL.

```
storage.StaticFilesStorage.post_process(paths, **options)
```

If this method is defined on a storage, it's called by the *collectstatic* management command after each run and gets passed the local storages and paths of found files as a dictionary, as well as the command line options. It yields tuples of three values: *original_path*, *processed_path*, *processed*. The path values are strings and *processed* is a boolean indicating whether or not the value was post-processed, or an exception if post-processing failed.

The *ManifestStaticFilesStorage* uses this behind the scenes to replace the paths with their hashed counterparts and update the cache appropriately.

ManifestStaticFilesStorage

```
class storage.ManifestStaticFilesStorage
```

A subclass of the *StaticFilesStorage* storage backend which stores the file names it handles by appending the MD5 hash of the file's content to the filename. For example, the file *css/styles.css* would also be saved as *css/styles.55e7cbb9ba48.css*.

The purpose of this storage is to keep serving the old files in case some pages still refer to those files, e.g. because they are cached by you or a 3rd party proxy server. Additionally, it's very helpful if you want to apply *far future Expires headers* to the deployed files to speed up the load time for subsequent page visits.

The storage backend automatically replaces the paths found in the saved files matching other saved files with the path of the cached copy (using the *post_process()* method). The regular expressions used to find those paths (*django.contrib.staticfiles.storage.HashedFilesMixin.patterns*) cover:

- The *@import* rule and *url()* statement of *Cascading Style Sheets*.
- *Source map* comments in CSS and JavaScript files.

Subclass *ManifestStaticFilesStorage* and set the *support_js_module_import_aggregation* attribute to *True*, if you want to use the experimental regular expressions to cover:

- The *modules import* in JavaScript.
- The *modules aggregation* in JavaScript.

For example, the *'css/styles.css'* file with this content:

```
@import url("../admin/css/base.css");
```

...would be replaced by calling the `url()` method of the `ManifestStaticFilesStorage` storage backend, ultimately saving a `'css/styles.55e7cbb9ba48.css'` file with the following content:

```
@import url("../admin/css/base.27e20196a850.css");
```

You can change the location of the manifest file by using a custom `ManifestStaticFilesStorage` subclass that sets the `manifest_storage` argument. For example:

```
from django.conf import settings
from django.contrib.staticfiles.storage import (
    ManifestStaticFilesStorage,
    StaticFilesStorage,
)

class MyManifestStaticFilesStorage(ManifestStaticFilesStorage):
    def __init__(self, *args, **kwargs):
        manifest_storage = StaticFilesStorage(location=settings.BASE_DIR)
        super().__init__(*args, manifest_storage=manifest_storage, **kwargs)
```

References in comments

`ManifestStaticFilesStorage` doesn't ignore paths in statements that are commented out. This [may crash on the nonexistent paths](#). You should check and eventually strip comments.

Support for finding paths in CSS source map comments was added.

Experimental optional support for finding paths to JavaScript modules in `import` and `export` statements was added.

`storage.ManifestStaticFilesStorage.manifest_hash`

This attribute provides a single hash that changes whenever a file in the manifest changes. This can be useful to communicate to SPAs that the assets on the server have changed (due to a new deployment).

`storage.ManifestStaticFilesStorage.max_post_process_passes`

Since static files might reference other static files that need to have their paths replaced, multiple passes of replacing paths may be needed until the file hashes converge. To prevent an infinite loop due to hashes not converging (for example, if `'foo.css'` references `'bar.css'` which references `'foo.css'`) there is a maximum number of passes before post-processing is abandoned. In cases with a large number of references, a higher number of passes might be needed. Increase the maximum number of passes by subclassing `ManifestStaticFilesStorage` and setting the `max_post_process_passes` attribute. It defaults to 5.

To enable the `ManifestStaticFilesStorage` you have to make sure the following requirements are met:

- the `staticfiles` storage backend in `STORAGES` setting is set to `'django.contrib.staticfiles.storage.ManifestStaticFilesStorage'`
- the `DEBUG` setting is set to `False`
- you've collected all your static files by using the `collectstatic` management command

Since creating the MD5 hash can be a performance burden to your website during runtime, `staticfiles` will automatically store the mapping with hashed names for all processed files in a file called `staticfiles.json`. This happens once when you run the `collectstatic` management command.

`storage.ManifestStaticFilesStorage.manifest_strict`

If a file isn't found in the `staticfiles.json` manifest at runtime, a `ValueError` is raised. This behavior can be disabled by subclassing `ManifestStaticFilesStorage` and setting the `manifest_strict` attribute to `False` –nonexistent paths will remain unchanged.

Due to the requirement of running `collectstatic`, this storage typically shouldn't be used when running tests as `collectstatic` isn't run as part of the normal test setup. During testing, ensure that `staticfiles` storage backend in the `STORAGES` setting is set to something else like `'django.contrib.staticfiles.storage.StaticFilesStorage'` (the default).

`storage.ManifestStaticFilesStorage.file_hash(name, content=None)`

The method that is used when creating the hashed name of a file. Needs to return a hash for the given file name and content. By default it calculates a MD5 hash from the content's chunks as mentioned above. Feel free to override this method to use your own hashing algorithm.

ManifestFilesMixin

```
class storage.ManifestFilesMixin
```

Use this mixin with a custom storage to append the MD5 hash of the file's content to the filename as `ManifestStaticFilesStorage` does.

Finders Module

`staticfiles` finders has a `searched_locations` attribute which is a list of directory paths in which the finders searched. Example usage:

```
from django.contrib.staticfiles import finders

result = finders.find("css/base.css")
searched_locations = finders.searched_locations
```

Other Helpers

There are a few other helpers outside of the `staticfiles` app to work with static files:

- The `django.template.context_processors.static()` context processor which adds `STATIC_URL` to every template context rendered with `RequestContext` contexts.
- The builtin template tag `static` which takes a path and urljoins it with the static prefix `STATIC_URL`. If `django.contrib.staticfiles` is installed, the tag uses the `url()` method of the `staticfiles` storage backend from `STORAGES` instead.
- The builtin template tag `get_static_prefix` which populates a template variable with the static prefix `STATIC_URL` to be used as a variable or directly.
- The similar template tag `get_media_prefix` which works like `get_static_prefix` but uses `MEDIA_URL`.
- The `staticfiles` key in `django.core.files.storage.storages` contains a ready-to-use instance of the `staticfiles` storage backend.

Static file development view

The static files tools are mostly designed to help with getting static files successfully deployed into production. This usually means a separate, dedicated static file server, which is a lot of overhead to mess with when developing locally. Thus, the `staticfiles` app ships with a quick and dirty helper view that you can use to serve files locally in development.

```
views.serve(request, path)
```

This view function serves static files in development.

Warning: This view will only work if `DEBUG` is `True`.

That's because this view is grossly inefficient and probably insecure. This is only intended for local development, and should never be used in production.

Note: To guess the served files' content types, this view relies on the `mimetypes` module from the Python standard library, which itself relies on the underlying platform's map files. If you find that this view doesn't return proper content types for certain files, it is most likely that the platform's map files are incorrect or need to be updated. This can be achieved, for example, by installing or updating the `mailcap` package on a Red Hat distribution, `mime-support` on a Debian distribution, or by editing the keys under `HKEY_CLASSES_ROOT` in the Windows registry.

This view is automatically enabled by `runserver` (with a `DEBUG` setting set to `True`). To use the view with a different local development server, add the following snippet to the end of your primary URL configuration:

```
from django.conf import settings
from django.contrib.staticfiles import views
from django.urls import re_path

if settings.DEBUG:
    urlpatterns += [
        re_path(r"^static/(?P<path>.*)$", views.serve),
    ]
```

Note, the beginning of the pattern (`r'^static/'`) should be your `STATIC_URL` setting.

Since this is a bit finicky, there's also a helper function that'll do this for you:

```
urls.staticfiles_urlpatterns()
```

This will return the proper URL pattern for serving static files to your already defined pattern list. Use it like this:

```
from django.contrib.staticfiles.urls import staticfiles_urlpatterns

# ... the rest of your URLconf here ...

urlpatterns += staticfiles_urlpatterns()
```

This will inspect your `STATIC_URL` setting and wire up the view to serve static files accordingly. Don't forget to set the `STATICFILES_DIRS` setting appropriately to let `django.contrib.staticfiles` know where to look for files in addition to files in app directories.

Warning: This helper function will only work if `DEBUG` is `True` and your `STATIC_URL` setting is neither empty nor a full URL such as `http://static.example.com/`.

That's because this view is grossly inefficient and probably insecure. This is only intended for local development, and should never be used in production.

Specialized test case to support 'live testing'

```
class testing.StaticLiveServerTestCase
```

This unittest TestCase subclass extends `django.test.LiveServerTestCase`.

Just like its parent, you can use it to write tests that involve running the code under test and consuming it with testing tools through HTTP (e.g. Selenium, PhantomJS, etc.), because of which it's needed that the static assets are also published.

But given the fact that it makes use of the `django.contrib.staticfiles.views.serve()` view described above, it can transparently overlay at test execution-time the assets provided by the `staticfiles` finders. This means you don't need to run `collectstatic` before or as a part of your tests setup.

6.5.13 The syndication feed framework

Django comes with a high-level syndication-feed-generating framework for creating [RSS](#) and [Atom](#) feeds.

To create any syndication feed, all you have to do is write a short Python class. You can create as many feeds as you want.

Django also comes with a lower-level feed-generating API. Use this if you want to generate feeds outside of a web context, or in some other lower-level way.

The high-level framework

Overview

The high-level feed-generating framework is supplied by the [Feed](#) class. To create a feed, write a [Feed](#) class and point to an instance of it in your [URLconf](#).

Feed classes

A [Feed](#) class is a Python class that represents a syndication feed. A feed can be simple (e.g., a “site news” feed, or a basic feed displaying the latest entries of a blog) or more complex (e.g., a feed displaying all the blog entries in a particular category, where the category is variable).

Feed classes subclass `django.contrib.syndication.views.Feed`. They can live anywhere in your codebase.

Instances of [Feed](#) classes are views which can be used in your [URLconf](#).

A simple example

This simple example, taken from a hypothetical police beat news site describes a feed of the latest five news items:

```
from django.contrib.syndication.views import Feed
from django.urls import reverse
from policebeat.models import NewsItem

class LatestEntriesFeed(Feed):
    title = "Police beat site news"
```

(continues on next page)

(continued from previous page)

```

link = "/sitenews/"
description = "Updates on changes and additions to police beat central."

def items(self):
    return NewsItem.objects.order_by("-pub_date")[:5]

def item_title(self, item):
    return item.title

def item_description(self, item):
    return item.description

# item_link is only needed if NewsItem has no get_absolute_url method.
def item_link(self, item):
    return reverse("news-item", args=[item.pk])

```

To connect a URL to this feed, put an instance of the Feed object in your [URLconf](#). For example:

```

from django.urls import path
from myproject.feeds import LatestEntriesFeed

urlpatterns = [
    # ...
    path("latest/feed/", LatestEntriesFeed()),
    # ...
]

```

Note:

- The Feed class subclasses `django.contrib.syndication.views.Feed`.
- `title`, `link` and `description` correspond to the standard RSS `<title>`, `<link>` and `<description>` elements, respectively.
- `items()` is a method that returns a list of objects that should be included in the feed as `<item>` elements. Although this example returns `NewsItem` objects using Django's [object-relational mapper](#), `items()` doesn't have to return model instances. Although you get a few bits of functionality “for free” by using Django models, `items()` can return any type of object you want.
- If you're creating an Atom feed, rather than an RSS feed, set the `subtitle` attribute instead of the `description` attribute. See [Publishing Atom and RSS feeds in tandem](#), later, for an example.

One thing is left to do. In an RSS feed, each `<item>` has a `<title>`, `<link>` and `<description>`. We need to tell the framework what data to put into those elements.

- For the contents of `<title>` and `<description>`, Django tries calling the methods `item_title()` and `item_description()` on the `Feed` class. They are passed a single parameter, `item`, which is the object

itself. These are optional; by default, the string representation of the object is used for both.

If you want to do any special formatting for either the title or description, [Django templates](#) can be used instead. Their paths can be specified with the `title_template` and `description_template` attributes on the `Feed` class. The templates are rendered for each item and are passed two template context variables:

- `{{ obj }}` –The current object (one of whichever objects you returned in `items()`).
- `{{ site }}` –A `django.contrib.sites.models.Site` object representing the current site. This is useful for `{{ site.domain }}` or `{{ site.name }}`. If you do not have the Django sites framework installed, this will be set to a `RequestSite` object. See the [RequestSite section of the sites framework documentation](#) for more.

See a [complex example](#) below that uses a description template.

`Feed.get_context_data(**kwargs)`

There is also a way to pass additional information to title and description templates, if you need to supply more than the two variables mentioned before. You can provide your implementation of `get_context_data` method in your `Feed` subclass. For example:

```
from mysite.models import Article
from django.contrib.syndication.views import Feed

class ArticlesFeed(Feed):
    title = "My articles"
    description_template = "feeds/articles.html"

    def items(self):
        return Article.objects.order_by("-pub_date")[:5]

    def get_context_data(self, **kwargs):
        context = super().get_context_data(**kwargs)
        context["foo"] = "bar"
        return context
```

And the template:

```
Something about {{ foo }}: {{ obj.description }}
```

This method will be called once per each item in the list returned by `items()` with the following keyword arguments:

- `item`: the current item. For backward compatibility reasons, the name of this context variable is `{{ obj }}`.
- `obj`: the object returned by `get_object()`. By default this is not exposed to the templates

to avoid confusion with `{{ obj }}` (see above), but you can use it in your implementation of `get_context_data()`.

- `site`: current site as described above.
- `request`: current request.

The behavior of `get_context_data()` mimics that of [generic views](#) - you're supposed to call `super()` to retrieve context data from parent class, add your data and return the modified dictionary.

- To specify the contents of `<link>`, you have two options. For each item in `items()`, Django first tries calling the `item_link()` method on the `Feed` class. In a similar way to the title and description, it is passed it a single parameter, `item`. If that method doesn't exist, Django tries executing a `get_absolute_url()` method on that object. Both `get_absolute_url()` and `item_link()` should return the item's URL as a normal Python string. As with `get_absolute_url()`, the result of `item_link()` will be included directly in the URL, so you are responsible for doing all necessary URL quoting and conversion to ASCII inside the method itself.

A complex example

The framework also supports more complex feeds, via arguments.

For example, a website could offer an RSS feed of recent crimes for every police beat in a city. It'd be silly to create a separate `Feed` class for each police beat; that would violate the [DRY principle](#) and would couple data to programming logic. Instead, the syndication framework lets you access the arguments passed from your `URLconf` so feeds can output items based on information in the feed's URL.

The police beat feeds could be accessible via URLs like this:

- `/beats/613/rss/` -Returns recent crimes for beat 613.
- `/beats/1424/rss/` -Returns recent crimes for beat 1424.

These can be matched with a `URLconf` line such as:

```
path("beats/<int:beat_id>/rss/", BeatFeed()),
```

Like a view, the arguments in the URL are passed to the `get_object()` method along with the request object.

Here's the code for these beat-specific feeds:

```
from django.contrib.syndication.views import Feed

class BeatFeed(Feed):
    description_template = "feeds/beat_description.html"

    def get_object(self, request, beat_id):
```

(continues on next page)

(continued from previous page)

```

    return Beat.objects.get(pk=beat_id)

    def title(self, obj):
        return "Police beat central: Crimes for beat %s" % obj.beat

    def link(self, obj):
        return obj.get_absolute_url()

    def description(self, obj):
        return "Crimes recently reported in police beat %s" % obj.beat

    def items(self, obj):
        return Crime.objects.filter(beat=obj).order_by("-crime_date")[:30]

```

To generate the feed's <title>, <link> and <description>, Django uses the `title()`, `link()` and `description()` methods. In the previous example, they were string class attributes, but this example illustrates that they can be either strings or methods. For each of `title`, `link` and `description`, Django follows this algorithm:

- First, it tries to call a method, passing the `obj` argument, where `obj` is the object returned by `get_object()`.
- Failing that, it tries to call a method with no arguments.
- Failing that, it uses the class attribute.

Also note that `items()` also follows the same algorithm –first, it tries `items(obj)`, then `items()`, then finally an `items` class attribute (which should be a list).

We are using a template for the item descriptions. It can be as minimal as this:

```
{{ obj.description }}
```

However, you are free to add formatting as desired.

The `ExampleFeed` class below gives full documentation on methods and attributes of *Feed* classes.

Specifying the type of feed

By default, feeds produced in this framework use RSS 2.0.

To change that, add a `feed_type` attribute to your *Feed* class, like so:

```
from django.utils.feedgenerator import Atom1Feed
```

(continues on next page)

(continued from previous page)

```
class MyFeed(Feed):
    feed_type = Atom1Feed
```

Note that you set `feed_type` to a class object, not an instance.

Currently available feed types are:

- `django.utils.feedgenerator.Rss201rev2Feed` (RSS 2.01. Default.)
- `django.utils.feedgenerator.RssUserland091Feed` (RSS 0.91.)
- `django.utils.feedgenerator.Atom1Feed` (Atom 1.0.)

Enclosures

To specify enclosures, such as those used in creating podcast feeds, use the `item_enclosures` hook or, alternatively and if you only have a single enclosure per item, the `item_enclosure_url`, `item_enclosure_length`, and `item_enclosure_mime_type` hooks. See the `ExampleFeed` class below for usage examples.

Language

Feeds created by the syndication framework automatically include the appropriate `<language>` tag (RSS 2.0) or `xml:lang` attribute (Atom). By default, this is `django.utils.translation.get_language()`. You can change it by setting the `language` class attribute.

URLs

The `link` method/attribute can return either an absolute path (e.g. `"/blog/"`) or a URL with the fully-qualified domain and protocol (e.g. `"https://www.example.com/blog/"`). If `link` doesn't return the domain, the syndication framework will insert the domain of the current site, according to your `SITE_ID` setting.

Atom feeds require a `<link rel="self">` that defines the feed's current location. The syndication framework populates this automatically, using the domain of the current site according to the `SITE_ID` setting.

Publishing Atom and RSS feeds in tandem

Some developers like to make available both Atom and RSS versions of their feeds. To do that, you can create a subclass of your `Feed` class and set the `feed_type` to something different. Then update your `URLconf` to add the extra versions.

Here's a full example:

```
from django.contrib.syndication.views import Feed
from policebeat.models import NewsItem
from django.utils.feedgenerator import Atom1Feed

class RssSiteNewsFeed(Feed):
    title = "Police beat site news"
    link = "/siteneews/"
    description = "Updates on changes and additions to police beat central."

    def items(self):
        return NewsItem.objects.order_by("-pub_date")[:5]

class AtomSiteNewsFeed(RssSiteNewsFeed):
    feed_type = Atom1Feed
    subtitle = RssSiteNewsFeed.description
```

Note: In this example, the RSS feed uses a `description` while the Atom feed uses a `subtitle`. That’s because Atom feeds don’t provide for a feed-level “description,” but they do provide for a “subtitle.”

If you provide a `description` in your `Feed` class, Django will not automatically put that into the `subtitle` element, because a subtitle and description are not necessarily the same thing. Instead, you should define a `subtitle` attribute.

In the above example, we set the Atom feed’s `subtitle` to the RSS feed’s `description`, because it’s quite short already.

And the accompanying URLconf:

```
from django.urls import path
from myproject.feeds import AtomSiteNewsFeed, RssSiteNewsFeed

urlpatterns = [
    # ...
    path("siteneews/rss/", RssSiteNewsFeed()),
    path("siteneews/atom/", AtomSiteNewsFeed()),
    # ...
]
```

Feed class reference

```
class views.Feed
```

This example illustrates all possible attributes and methods for a *Feed* class:

```
from django.contrib.syndication.views import Feed
from django.utils import feedgenerator

class ExampleFeed(Feed):
    # FEED TYPE -- Optional. This should be a class that subclasses
    # django.utils.feedgenerator.SyndicationFeed. This designates
    # which type of feed this should be: RSS 2.0, Atom 1.0, etc. If
    # you don't specify feed_type, your feed will be RSS 2.0. This
    # should be a class, not an instance of the class.

    feed_type = feedgenerator.Rss201rev2Feed

    # TEMPLATE NAMES -- Optional. These should be strings
    # representing names of Django templates that the system should
    # use in rendering the title and description of your feed items.
    # Both are optional. If a template is not specified, the
    # item_title() or item_description() methods are used instead.

    title_template = None
    description_template = None

    # LANGUAGE -- Optional. This should be a string specifying a language
    # code. Defaults to django.utils.translation.get_language().
    language = "de"

    # TITLE -- One of the following three is required. The framework
    # looks for them in this order.

    def title(self, obj):
        """
        Takes the object returned by get_object() and returns the
        feed's title as a normal Python string.
        """

    def title(self):
        """
        Returns the feed's title as a normal Python string.
        """
```

(continues on next page)

(continued from previous page)

```
title = "foo" # Hard-coded title.

# LINK -- One of the following three is required. The framework
# looks for them in this order.

def link(self, obj):
    """
    # Takes the object returned by get_object() and returns the URL
    # of the HTML version of the feed as a normal Python string.
    """

def link(self):
    """
    Returns the URL of the HTML version of the feed as a normal Python
    string.
    """

link = "/blog/" # Hard-coded URL.

# FEED_URL -- One of the following three is optional. The framework
# looks for them in this order.

def feed_url(self, obj):
    """
    # Takes the object returned by get_object() and returns the feed's
    # own URL as a normal Python string.
    """

        Returns the comments URL for every item in the feed.
        """

    item_comments = "https://www.example.com/comments" # Hard-coded comments URL

```

The low-level framework

Behind the scenes, the high-level RSS framework uses a lower-level framework for generating feeds' XML. This framework lives in a single module: `django/utils/feedgenerator.py`.

You use this framework on your own, for lower-level feed generation. You can also create custom feed generator subclasses for use with the `feed_type` Feed option.

SyndicationFeed classes

The `feedgenerator` module contains a base class:

- `django.utils.feedgenerator.SyndicationFeed`

and several subclasses:

- `django.utils.feedgenerator.RssUserland091Feed`
- `django.utils.feedgenerator.Rss201rev2Feed`
- `django.utils.feedgenerator.Atom1Feed`

Each of these three classes knows how to render a certain type of feed as XML. They share this interface:

`SyndicationFeed.__init__()`

Initialize the feed with the given dictionary of metadata, which applies to the entire feed. Required keyword arguments are:

- `title`
- `link`
- `description`

There' s also a bunch of other optional keywords:

- `language`

- `author_email`
- `author_name`
- `author_link`
- `subtitle`
- `categories`
- `feed_url`
- `feed_copyright`
- `feed_guid`
- `ttl`

Any extra keyword arguments you pass to `__init__` will be stored in `self.feed` for use with [custom feed generators](#).

All parameters should be strings, except `categories`, which should be a sequence of strings. Beware that some control characters are [not allowed](#) in XML documents. If your content has some of them, you might encounter a `ValueError` when producing the feed.

`SyndicationFeed.add_item()`

Add an item to the feed with the given parameters.

Required keyword arguments are:

- `title`
- `link`
- `description`

Optional keyword arguments are:

- `author_email`
- `author_name`
- `author_link`
- `pubdate`
- `comments`
- `unique_id`
- `enclosures`
- `categories`
- `item_copyright`
- `ttl`

- `updateddate`

Extra keyword arguments will be stored for [custom feed generators](#).

All parameters, if given, should be strings, except:

- `pubdate` should be a Python `datetime` object.
- `updateddate` should be a Python `datetime` object.
- `enclosures` should be a list of `django.utils.feedgenerator.Enclosure` instances.
- `categories` should be a sequence of strings.

`SyndicationFeed.write()`

Outputs the feed in the given encoding to outfile, which is a file-like object.

`SyndicationFeed.writeString()`

Returns the feed as a string in the given encoding.

For example, to create an Atom 1.0 feed and print it to standard output:

```
>>> from django.utils import feedgenerator
>>> from datetime import datetime
>>> f = feedgenerator.Atom1Feed(
...     title="My Blog",
...     link="https://www.example.com/",
...     description="In which I write about what I ate today.",
...     language="en",
...     author_name="Myself",
...     feed_url="https://example.com/atom.xml",
... )
>>> f.add_item(
...     title="Hot dog today",
...     link="https://www.example.com/entries/1/",
...     pubdate=datetime.now(),
...     description="<p>Today I had a Vienna Beef hot dog. It was pink, plump and perfect.</p>",
... )
>>> print(f.writeString("UTF-8"))
<?xml version="1.0" encoding="UTF-8"?>
<feed xmlns="http://www.w3.org/2005/Atom" xml:lang="en">
...
</feed>
```

Custom feed generators

If you need to produce a custom feed format, you’ ve got a couple of options.

If the feed format is totally custom, you’ ll want to subclass `SyndicationFeed` and completely replace the `write()` and `writeString()` methods.

However, if the feed format is a spin-off of RSS or Atom (i.e. [GeoRSS](#), Apple’ s [iTunes podcast format](#), etc.), you’ ve got a better choice. These types of feeds typically add extra elements and/or attributes to the underlying format, and there are a set of methods that `SyndicationFeed` calls to get these extra attributes. Thus, you can subclass the appropriate feed generator class (`Atom1Feed` or `Rss201rev2Feed`) and extend these callbacks. They are:

`SyndicationFeed.root_attributes(self)`

Return a dict of attributes to add to the root feed element (`feed/channel`).

`SyndicationFeed.add_root_elements(self, handler)`

Callback to add elements inside the root feed element (`feed/channel`). `handler` is an [XMLGenerator](#) from Python’ s built-in SAX library; you’ ll call methods on it to add to the XML document in process.

`SyndicationFeed.item_attributes(self, item)`

Return a dict of attributes to add to each item (`item/entry`) element. The argument, `item`, is a dictionary of all the data passed to `SyndicationFeed.add_item()`.

`SyndicationFeed.add_item_elements(self, handler, item)`

Callback to add elements to each item (`item/entry`) element. `handler` and `item` are as above.

Warning: If you override any of these methods, be sure to call the superclass methods since they add the required elements for each feed format.

For example, you might start implementing an iTunes RSS feed generator like so:

```
class iTunesFeed(Rss201rev2Feed):
    def root_attributes(self):
        attrs = super().root_attributes()
        attrs["xmlns:itunes"] = "http://www.itunes.com/dtlds/podcast-1.0.dtd"
        return attrs

    def add_root_elements(self, handler):
        super().add_root_elements(handler)
        handler.addQuickElement("itunes:explicit", "clean")
```

There’ s a lot more work to be done for a complete custom feed class, but the above example should demonstrate the basic idea.

6.5.14 admin

The automatic Django administrative interface. For more information, see [Tutorial 2](#) and the [admin documentation](#).

Requires the [auth](#) and [contenttypes](#) contrib packages to be installed.

6.5.15 auth

Django’s authentication framework.

See [User authentication in Django](#).

6.5.16 contenttypes

A light framework for hooking into “types” of content, where each installed Django model is a separate content type.

See the [contenttypes documentation](#).

6.5.17 flatpages

A framework for managing “flat” HTML content in a database.

See the [flatpages documentation](#).

Requires the [sites](#) contrib package to be installed as well.

6.5.18 gis

A world-class geospatial framework built on top of Django, that enables storage, manipulation and display of spatial data.

See the [GeoDjango documentation](#) for more.

6.5.19 humanize

A set of Django template filters useful for adding a “human touch” to data.

See the [humanize documentation](#).

6.5.20 messages

A framework for storing and retrieving temporary cookie- or session-based messages

See the [messages documentation](#).

6.5.21 postgres

A collection of PostgreSQL specific features.

See the [contrib.postgres documentation](#).

6.5.22 redirects

A framework for managing redirects.

See the [redirects documentation](#).

6.5.23 sessions

A framework for storing data in anonymous sessions.

See the [sessions documentation](#).

6.5.24 sites

A light framework that lets you operate multiple websites off of the same database and Django installation. It gives you hooks for associating objects to one or more sites.

See the [sites documentation](#).

6.5.25 sitemaps

A framework for generating Google sitemap XML files.

See the [sitemaps documentation](#).

6.5.26 syndication

A framework for generating syndication feeds, in RSS and Atom, quite easily.

See the [syndication documentation](#).

6.5.27 Other add-ons

If you have an idea for functionality to include in `contrib`, let us know! Code it up, and post it to the [django-users](#) mailing list.

6.6 Cross Site Request Forgery protection

The CSRF middleware and template tag provides easy-to-use protection against [Cross Site Request Forgeries](#). This type of attack occurs when a malicious website contains a link, a form button or some JavaScript that is intended to perform some action on your website, using the credentials of a logged-in user who visits the malicious site in their browser. A related type of attack, ‘login CSRF’, where an attacking site tricks a user’s browser into logging into a site with someone else’s credentials, is also covered.

The first defense against CSRF attacks is to ensure that GET requests (and other ‘safe’ methods, as defined by [RFC 9110#section-9.2.1](#)) are side effect free. Requests via ‘unsafe’ methods, such as POST, PUT, and DELETE, can then be protected by the steps outlined in [How to use Django’s CSRF protection](#).

6.6.1 How it works

The CSRF protection is based on the following things:

1. A CSRF cookie that is a random secret value, which other sites will not have access to.

`CsrfViewMiddleware` sends this cookie with the response whenever `django.middleware.csrf.get_token()` is called. It can also send it in other cases. For security reasons, the value of the secret is changed each time a user logs in.

2. A hidden form field with the name ‘`csrfmiddlewaretoken`’, present in all outgoing POST forms.

In order to protect against [BREACH](#) attacks, the value of this field is not simply the secret. It is scrambled differently with each response using a mask. The mask is generated randomly on every call to `get_token()`, so the form field value is different each time.

This part is done by the template tag.

3. For all incoming requests that are not using HTTP GET, HEAD, OPTIONS or TRACE, a CSRF cookie must be present, and the ‘`csrfmiddlewaretoken`’ field must be present and correct. If it isn’t, the user will get a 403 error.

When validating the ‘`csrfmiddlewaretoken`’ field value, only the secret, not the full token, is compared with the secret in the cookie value. This allows the use of ever-changing tokens. While each request may use its own token, the secret remains common to all.

This check is done by `CsrfViewMiddleware`.

4. `CsrfViewMiddleware` verifies the [Origin header](#), if provided by the browser, against the current host and the `CSRF_TRUSTED_ORIGINS` setting. This provides protection against cross-subdomain attacks.
5. In addition, for HTTPS requests, if the `Origin` header isn’t provided, `CsrfViewMiddleware` performs strict referer checking. This means that even if a subdomain can set or modify cookies on your domain, it can’t force a user to post to your application since that request won’t come from your own exact domain.

This also addresses a man-in-the-middle attack that’s possible under HTTPS when using a session independent secret, due to the fact that `HTTP Set-Cookie` headers are (unfortunately) accepted by clients even when they are talking to a site under HTTPS. (Referer checking is not done for HTTP requests because the presence of the `Referer` header isn’t reliable enough under HTTP.)

If the `CSRF_COOKIE_DOMAIN` setting is set, the referer is compared against it. You can allow cross-subdomain requests by including a leading dot. For example, `CSRF_COOKIE_DOMAIN = '.example.com'` will allow POST requests from `www.example.com` and `api.example.com`. If the setting is not set, then the referer must match the `HTTP Host` header.

Expanding the accepted referers beyond the current host or cookie domain can be done with the `CSRF_TRUSTED_ORIGINS` setting.

In older versions, the CSRF cookie value was masked.

This ensures that only forms that have originated from trusted domains can be used to POST data back.

It deliberately ignores GET requests (and other requests that are defined as ‘safe’ by [RFC 9110#section-9.2.1](#)). These requests ought never to have any potentially dangerous side effects, and so a CSRF attack with a GET request ought to be harmless. [RFC 9110#section-9.2.1](#) defines POST, PUT, and DELETE as ‘unsafe’, and all other methods are also assumed to be unsafe, for maximum protection.

The CSRF protection cannot protect against man-in-the-middle attacks, so use [HTTPS](#) with [HTTP Strict Transport Security](#). It also assumes [validation of the HOST header](#) and that there aren’t any [cross-site scripting vulnerabilities](#) on your site (because XSS vulnerabilities already let an attacker do anything a CSRF vulnerability allows and much worse).

Removing the `Referer` header

To avoid disclosing the referrer URL to third-party sites, you might want to [disable the referer](#) on your site’s `<a>` tags. For example, you might use the `<meta name="referrer" content="no-referrer">` tag or include the `Referrer-Policy: no-referrer` header. Due to the CSRF protection’s strict referer checking on HTTPS requests, those techniques cause a CSRF failure on requests with ‘unsafe’ methods. Instead, use

alternatives like `<a rel="noreferrer" ...>` for links to third-party sites.

6.6.2 Limitations

Subdomains within a site will be able to set cookies on the client for the whole domain. By setting the cookie and using a corresponding token, subdomains will be able to circumvent the CSRF protection. The only way to avoid this is to ensure that subdomains are controlled by trusted users (or, are at least unable to set cookies). Note that even without CSRF, there are other vulnerabilities, such as session fixation, that make giving subdomains to untrusted parties a bad idea, and these vulnerabilities cannot easily be fixed with current browsers.

6.6.3 Utilities

The examples below assume you are using function-based views. If you are working with class-based views, you can refer to [Decorating class-based views](#).

`csrf_exempt`(view)

This decorator marks a view as being exempt from the protection ensured by the middleware. Example:

```
from django.http import HttpResponse
from django.views.decorators.csrf import csrf_exempt

@csrf_exempt
def my_view(request):
    return HttpResponse("Hello world")
```

`csrf_protect`(view)

Decorator that provides the protection of `CsrfViewMiddleware` to a view.

Usage:

```
from django.shortcuts import render
from django.views.decorators.csrf import csrf_protect

@csrf_protect
def my_view(request):
    c = {}
    # ...
    return render(request, "a_template.html", c)
```

`requires_csrf_token(view)`

Normally the `csrf_token` template tag will not work if `CsrfViewMiddleware.process_view` or an equivalent like `csrf_protect` has not run. The view decorator `requires_csrf_token` can be used to ensure the template tag does work. This decorator works similarly to `csrf_protect`, but never rejects an incoming request.

Example:

```
from django.shortcuts import render
from django.views.decorators.csrf import requires_csrf_token

@requires_csrf_token
def my_view(request):
    c = {}
    # ...
    return render(request, "a_template.html", c)
```

`ensure_csrf_cookie(view)`

This decorator forces a view to send the CSRF cookie.

6.6.4 Settings

A number of settings can be used to control Django's CSRF behavior:

- `CSRF_COOKIE_AGE`
- `CSRF_COOKIE_DOMAIN`
- `CSRF_COOKIE_HTTPONLY`
- `CSRF_COOKIE_NAME`
- `CSRF_COOKIE_PATH`
- `CSRF_COOKIE_SAMESITE`
- `CSRF_COOKIE_SECURE`
- `CSRF_FAILURE_VIEW`
- `CSRF_HEADER_NAME`
- `CSRF_TRUSTED_ORIGINS`
- `CSRF_USE_SESSIONS`

6.6.5 Frequently Asked Questions

Is posting an arbitrary CSRF token pair (cookie and POST data) a vulnerability?

No, this is by design. Without a man-in-the-middle attack, there is no way for an attacker to send a CSRF token cookie to a victim's browser, so a successful attack would need to obtain the victim's browser's cookie via XSS or similar, in which case an attacker usually doesn't need CSRF attacks.

Some security audit tools flag this as a problem but as mentioned before, an attacker cannot steal a user's browser's CSRF cookie. "Stealing" or modifying your own token using Firebug, Chrome dev tools, etc. isn't a vulnerability.

Is it a problem that Django's CSRF protection isn't linked to a session by default?

No, this is by design. Not linking CSRF protection to a session allows using the protection on sites such as a pastebin that allow submissions from anonymous users which don't have a session.

If you wish to store the CSRF token in the user's session, use the `CSRF_USE_SESSIONS` setting.

Why might a user encounter a CSRF validation failure after logging in?

For security reasons, CSRF tokens are rotated each time a user logs in. Any page with a form generated before a login will have an old, invalid CSRF token and need to be reloaded. This might happen if a user uses the back button after a login or if they log in a different browser tab.

6.7 Databases

Django officially supports the following databases:

- PostgreSQL
- MariaDB
- MySQL
- Oracle
- SQLite

There are also a number of database backends provided by third parties.

Django attempts to support as many features as possible on all database backends. However, not all database backends are alike, and we've had to make design decisions on which features to support and which assumptions we can make safely.

This file describes some of the features that might be relevant to Django usage. It is not intended as a replacement for server-specific documentation or reference manuals.

6.7.1 General notes

Persistent connections

Persistent connections avoid the overhead of reestablishing a connection to the database in each HTTP request. They're controlled by the `CONN_MAX_AGE` parameter which defines the maximum lifetime of a connection. It can be set independently for each database.

The default value is 0, preserving the historical behavior of closing the database connection at the end of each request. To enable persistent connections, set `CONN_MAX_AGE` to a positive integer of seconds. For unlimited persistent connections, set it to `None`.

Connection management

Django opens a connection to the database when it first makes a database query. It keeps this connection open and reuses it in subsequent requests. Django closes the connection once it exceeds the maximum age defined by `CONN_MAX_AGE` or when it isn't usable any longer.

In detail, Django automatically opens a connection to the database whenever it needs one and doesn't have one already —either because this is the first connection, or because the previous connection was closed.

At the beginning of each request, Django closes the connection if it has reached its maximum age. If your database terminates idle connections after some time, you should set `CONN_MAX_AGE` to a lower value, so that Django doesn't attempt to use a connection that has been terminated by the database server. (This problem may only affect very low traffic sites.)

At the end of each request, Django closes the connection if it has reached its maximum age or if it is in an unrecoverable error state. If any database errors have occurred while processing the requests, Django checks whether the connection still works, and closes it if it doesn't. Thus, database errors affect at most one request per each application's worker thread; if the connection becomes unusable, the next request gets a fresh connection.

Setting `CONN_HEALTH_CHECKS` to `True` can be used to improve the robustness of connection reuse and prevent errors when a connection has been closed by the database server which is now ready to accept and serve new connections, e.g. after database server restart. The health check is performed only once per request and only if the database is being accessed during the handling of the request.

The `CONN_HEALTH_CHECKS` setting was added.

Caveats

Since each thread maintains its own connection, your database must support at least as many simultaneous connections as you have worker threads.

Sometimes a database won't be accessed by the majority of your views, for example because it's the database of an external system, or thanks to caching. In such cases, you should set `CONN_MAX_AGE` to a low value or even 0, because it doesn't make sense to maintain a connection that's unlikely to be reused. This will help keep the number of simultaneous connections to this database small.

The development server creates a new thread for each request it handles, negating the effect of persistent connections. Don't enable them during development.

When Django establishes a connection to the database, it sets up appropriate parameters, depending on the backend being used. If you enable persistent connections, this setup is no longer repeated every request. If you modify parameters such as the connection's isolation level or time zone, you should either restore Django's defaults at the end of each request, force an appropriate value at the beginning of each request, or disable persistent connections.

If a connection is created in a long-running process, outside of Django's request-response cycle, the connection will remain open until explicitly closed, or timeout occurs.

Encoding

Django assumes that all databases use UTF-8 encoding. Using other encodings may result in unexpected behavior such as “value too long” errors from your database for data that is valid in Django. See the database specific notes below for information on how to set up your database correctly.

6.7.2 PostgreSQL notes

Django supports PostgreSQL 12 and higher. `psycopg` 3.1.8+ or `psycopg2` 2.8.4+ is required, though the latest `psycopg` 3.1.8+ is recommended.

Note: Support for `psycopg2` is likely to be deprecated and removed at some point in the future.

Support for `psycopg` 3.1.8+ was added.

PostgreSQL connection settings

See [HOST](#) for details.

To connect using a service name from the [connection service file](#) and a password from the [password file](#), you must specify them in the [OPTIONS](#) part of your database configuration in [DATABASES](#):

Listing 7: settings.py

```
DATABASES = {
    "default": {
        "ENGINE": "django.db.backends.postgresql",
        "OPTIONS": {
            "service": "my_service",
            "passfile": ".my_pgpass",
        },
    },
}
```

Listing 8: .pg_service.conf

```
[my_service]
host=localhost
user=USER
dbname=NAME
port=5432
```

Listing 9: .my_pgpass

```
localhost:5432:NAME:USER:PASSWORD
```

Warning: Using a service name for testing purposes is not supported. This [may be implemented later](#).

Optimizing PostgreSQL's configuration

Django needs the following parameters for its database connections:

- `client_encoding`: 'UTF8',
- `default_transaction_isolation`: 'read committed' by default, or the value set in the connection options (see below),
- `timezone`:
 - when [USE_TZ](#) is True, 'UTC' by default, or the [TIME_ZONE](#) value set for the connection,

- when `USE_TZ` is `False`, the value of the global `TIME_ZONE` setting.

If these parameters already have the correct values, Django won't set them for every new connection, which improves performance slightly. You can configure them directly in `postgresql.conf` or more conveniently per database user with `ALTER ROLE`.

Django will work just fine without this optimization, but each new connection will do some additional queries to set these parameters.

Isolation level

Like PostgreSQL itself, Django defaults to the `READ COMMITTED` isolation level. If you need a higher isolation level such as `REPEATABLE READ` or `SERIALIZABLE`, set it in the `OPTIONS` part of your database configuration in `DATABASES`:

```
from django.db.backends.postgresql.psycopg_any import IsolationLevel

DATABASES = {
    # ...
    "OPTIONS": {
        "isolation_level": IsolationLevel.SERIALIZABLE,
    },
}
```

Note: Under higher isolation levels, your application should be prepared to handle exceptions raised on serialization failures. This option is designed for advanced uses.

`IsolationLevel` was added.

Role

If you need to use a different role for database connections than the role used to establish the connection, set it in the `OPTIONS` part of your database configuration in `DATABASES`:

```
DATABASES = {
    "default": {
        "ENGINE": "django.db.backends.postgresql",
        # ...
        "OPTIONS": {
            "assume_role": "my_application_role",
        },
    },
}
```

Server-side parameters binding

With `psycopg 3.1.8+`, Django defaults to the [client-side binding cursors](#). If you want to use the [server-side binding](#) set it in the `OPTIONS` part of your database configuration in `DATABASES`:

```
DATABASES = {
    "default": {
        "ENGINE": "django.db.backends.postgresql",
        # ...
        "OPTIONS": {
            "server_side_binding": True,
        },
    },
}
```

This option is ignored with `psycopg2`.

Indexes for varchar and text columns

When specifying `db_index=True` on your model fields, Django typically outputs a single `CREATE INDEX` statement. However, if the database type for the field is either `varchar` or `text` (e.g., used by `CharField`, `FileField`, and `TextField`), then Django will create an additional index that uses an appropriate [PostgreSQL operator class](#) for the column. The extra index is necessary to correctly perform lookups that use the `LIKE` operator in their SQL, as is done with the `contains` and `startswith` lookup types.

Migration operation for adding extensions

If you need to add a PostgreSQL extension (like `hstore`, `postgis`, etc.) using a migration, use the `CreateExtension` operation.

Server-side cursors

When using `QuerySet.iterator()`, Django opens a [server-side cursor](#). By default, PostgreSQL assumes that only the first 10% of the results of cursor queries will be fetched. The query planner spends less time planning the query and starts returning results faster, but this could diminish performance if more than 10% of the results are retrieved. PostgreSQL's assumptions on the number of rows retrieved for a cursor query is controlled with the `cursor_tuple_fraction` option.

Transaction pooling and server-side cursors

Using a connection pooler in transaction pooling mode (e.g. [PgBouncer](#)) requires disabling server-side cursors for that connection.

Server-side cursors are local to a connection and remain open at the end of a transaction when `AUTOCOMMIT` is `True`. A subsequent transaction may attempt to fetch more results from a server-side cursor. In transaction pooling mode, there's no guarantee that subsequent transactions will use the same connection. If a different connection is used, an error is raised when the transaction references the server-side cursor, because server-side cursors are only accessible in the connection in which they were created.

One solution is to disable server-side cursors for a connection in `DATABASES` by setting `DISABLE_SERVER_SIDE_CURSORS` to `True`.

To benefit from server-side cursors in transaction pooling mode, you could set up [another connection to the database](#) in order to perform queries that use server-side cursors. This connection needs to either be directly to the database or to a connection pooler in session pooling mode.

Another option is to wrap each `QuerySet` using server-side cursors in an `atomic()` block, because it disables `autocommit` for the duration of the transaction. This way, the server-side cursor will only live for the duration of the transaction.

Manually-specifying values of auto-incrementing primary keys

Django uses PostgreSQL's identity columns to store auto-incrementing primary keys. An identity column is populated with values from a [sequence](#) that keeps track of the next available value. Manually assigning a value to an auto-incrementing field doesn't update the field's sequence, which might later cause a conflict. For example:

```
>>> from django.contrib.auth.models import User
>>> User.objects.create(username="alice", pk=1)
<User: alice>
>>> # The sequence hasn't been updated; its next value is 1.
>>> User.objects.create(username="bob")
IntegrityError: duplicate key value violates unique constraint
"auth_user_pkey" DETAIL: Key (id)=(1) already exists.
```

If you need to specify such values, reset the sequence afterward to avoid reusing a value that's already in the table. The `sqlsequencereset` management command generates the SQL statements to do that.

In older versions, PostgreSQL's `SERIAL` data type was used instead of identity columns.

Test database templates

You can use the `TEST['TEMPLATE']` setting to specify a [template](#) (e.g. `'template0'`) from which to create a test database.

Speeding up test execution with non-durable settings

You can speed up test execution times by [configuring PostgreSQL to be non-durable](#).

Warning: This is dangerous: it will make your database more susceptible to data loss or corruption in the case of a server crash or power loss. Only use this on a development machine where you can easily restore the entire contents of all databases in the cluster.

6.7.3 MariaDB notes

Django supports MariaDB 10.4 and higher.

To use MariaDB, use the MySQL backend, which is shared between the two. See the [MySQL notes](#) for more details.

6.7.4 MySQL notes

Version support

Django supports MySQL 8 and higher.

Django's `inspectdb` feature uses the `information_schema` database, which contains detailed data on all database schemas.

Django expects the database to support Unicode (UTF-8 encoding) and delegates to it the task of enforcing transactions and referential integrity. It is important to be aware of the fact that the two latter ones aren't actually enforced by MySQL when using the MyISAM storage engine, see the next section.

Storage engines

MySQL has several [storage engines](#). You can change the default storage engine in the server configuration.

MySQL's default storage engine is [InnoDB](#). This engine is fully transactional and supports foreign key references. It's the recommended choice. However, the InnoDB autoincrement counter is lost on a MySQL restart because it does not remember the `AUTO_INCREMENT` value, instead recreating it as `"max(id)+1"`. This may result in an inadvertent reuse of [AutoField](#) values.

The main drawbacks of [MyISAM](#) are that it doesn't support transactions or enforce foreign-key constraints.

MySQL DB API Drivers

MySQL has a couple drivers that implement the Python Database API described in [PEP 249](#):

- [mysqlclient](#) is a native driver. It's the recommended choice.
- [MySQL Connector/Python](#) is a pure Python driver from Oracle that does not require the MySQL client library or any Python modules outside the standard library.

These drivers are thread-safe and provide connection pooling.

In addition to a DB API driver, Django needs an adapter to access the database drivers from its ORM. Django provides an adapter for [mysqlclient](#) while [MySQL Connector/Python](#) includes [its own](#).

mysqlclient

Django requires [mysqlclient](#) 1.4.3 or later.

MySQL Connector/Python

MySQL Connector/Python is available from the [download page](#). The Django adapter is available in versions 1.1.X and later. It may not support the most recent releases of Django.

Time zone definitions

If you plan on using Django's [timezone support](#), use [mysql_tzinfo_to_sql](#) to load time zone tables into the MySQL database. This needs to be done just once for your MySQL server, not per database.

Creating your database

You can [create your database](#) using the command-line tools and this SQL:

```
CREATE DATABASE <dbname> CHARACTER SET utf8;
```

This ensures all tables and columns will use UTF-8 by default.

Collation settings

The collation setting for a column controls the order in which data is sorted as well as what strings compare as equal. You can specify the `db_collation` parameter to set the collation name of the column for [CharField](#) and [TextField](#).

The collation can also be set on a database-wide level and per-table. This is [documented thoroughly](#) in the MySQL documentation. In such cases, you must set the collation by directly manipulating the database settings or tables. Django doesn't provide an API to change them.

By default, with a UTF-8 database, MySQL will use the `utf8_general_ci` collation. This results in all string equality comparisons being done in a case-insensitive manner. That is, "Fred" and "freD" are considered equal at the database level. If you have a unique constraint on a field, it would be illegal to try to insert both "aa" and "AA" into the same column, since they compare as equal (and, hence, non-unique) with the default collation. If you want case-sensitive comparisons on a particular column or table, change the column or table to use the `utf8_bin` collation.

Please note that according to [MySQL Unicode Character Sets](#), comparisons for the `utf8_general_ci` collation are faster, but slightly less correct, than comparisons for `utf8_unicode_ci`. If this is acceptable for your application, you should use `utf8_general_ci` because it is faster. If this is not acceptable (for example, if you require German dictionary order), use `utf8_unicode_ci` because it is more accurate.

Warning: Model formsets validate unique fields in a case-sensitive manner. Thus when using a case-insensitive collation, a formset with unique field values that differ only by case will pass validation, but upon calling `save()`, an `IntegrityError` will be raised.

Connecting to the database

Refer to the [settings documentation](#).

Connection settings are used in this order:

1. [OPTIONS](#).
2. [NAME](#), [USER](#), [PASSWORD](#), [HOST](#), [PORT](#)
3. MySQL option files.

In other words, if you set the name of the database in [OPTIONS](#), this will take precedence over [NAME](#), which would override anything in a [MySQL option file](#).

Here's a sample configuration which uses a MySQL option file:

```
# settings.py
DATABASES = {
    "default": {
        "ENGINE": "django.db.backends.mysql",
        "OPTIONS": {
            "read_default_file": "/path/to/my.cnf",
        },
    },
}
```

```
# my.cnf
[client]
database = NAME
user = USER
password = PASSWORD
default-character-set = utf8
```

Several other `MySQLdb` connection options may be useful, such as `ssl`, `init_command`, and `sql_mode`.

Setting `sql_mode`

The default value of the `sql_mode` option contains `STRICT_TRANS_TABLES`. That option escalates warnings into errors when data are truncated upon insertion, so Django highly recommends activating a `strict mode` for MySQL to prevent data loss (either `STRICT_TRANS_TABLES` or `STRICT_ALL_TABLES`).

If you need to customize the SQL mode, you can set the `sql_mode` variable like other MySQL options: either in a config file or with the entry `'init_command': "SET sql_mode='STRICT_TRANS_TABLES'"` in the `OPTIONS` part of your database configuration in `DATABASES`.

Isolation level

When running concurrent loads, database transactions from different sessions (say, separate threads handling different requests) may interact with each other. These interactions are affected by each session's `transaction isolation level`. You can set a connection's isolation level with an `'isolation_level'` entry in the `OPTIONS` part of your database configuration in `DATABASES`. Valid values for this entry are the four standard isolation levels:

- `'read uncommitted'`
- `'read committed'`
- `'repeatable read'`
- `'serializable'`

or `None` to use the server's configured isolation level. However, Django works best with and defaults to `read committed` rather than MySQL's default, `repeatable read`. Data loss is possible with `repeatable read`. In particular, you may see cases where `get_or_create()` will raise an `IntegrityError` but the object won't appear in a subsequent `get()` call.

Creating your tables

When Django generates the schema, it doesn't specify a storage engine, so tables will be created with whatever default storage engine your database server is configured for. The easiest solution is to set your database server's default storage engine to the desired engine.

If you're using a hosting service and can't change your server's default storage engine, you have a couple of options.

- After the tables are created, execute an `ALTER TABLE` statement to convert a table to a new storage engine (such as InnoDB):

```
ALTER TABLE <tablename> ENGINE=INNODB;
```

This can be tedious if you have a lot of tables.

- Another option is to use the `init_command` option for `MySQLdb` prior to creating your tables:

```
"OPTIONS": {  
    "init_command": "SET default_storage_engine=INNODB",  
}
```

This sets the default storage engine upon connecting to the database. After your tables have been created, you should remove this option as it adds a query that is only needed during table creation to each database connection.

Table names

There are [known issues](#) in even the latest versions of MySQL that can cause the case of a table name to be altered when certain SQL statements are executed under certain conditions. It is recommended that you use lowercase table names, if possible, to avoid any problems that might arise from this behavior. Django uses lowercase table names when it auto-generates table names from models, so this is mainly a consideration if you are overriding the table name via the `db_table` parameter.

Savepoints

Both the Django ORM and MySQL (when using the InnoDB [storage engine](#)) support database [savepoints](#).

If you use the MyISAM storage engine please be aware of the fact that you will receive database-generated errors if you try to use the [savepoint-related methods of the transactions API](#). The reason for this is that detecting the storage engine of a MySQL database/table is an expensive operation so it was decided it isn't worth to dynamically convert these methods in no-op's based in the results of such detection.

Notes on specific fields

Character fields

Any fields that are stored with `VARCHAR` column types may have their `max_length` restricted to 255 characters if you are using `unique=True` for the field. This affects *CharField*, *SlugField*. See [the MySQL documentation](#) for more details.

TextField limitations

MySQL can index only the first N chars of a BLOB or TEXT column. Since `TextField` doesn't have a defined length, you can't mark it as `unique=True`. MySQL will report: “BLOB/TEXT column ‘<db_column>’ used in key specification without a key length” .

Fractional seconds support for Time and DateTime fields

MySQL can store fractional seconds, provided that the column definition includes a fractional indication (e.g. `DATETIME(6)`).

Django will not upgrade existing columns to include fractional seconds if the database server supports it. If you want to enable them on an existing database, it's up to you to either manually update the column on the target database, by executing a command like:

```
ALTER TABLE `your_table` MODIFY `your_datetime_column` DATETIME(6)
```

or using a *RunSQL* operation in a [data migration](#).

TIMESTAMP columns

If you are using a legacy database that contains `TIMESTAMP` columns, you must set `USE_TZ = False` to avoid data corruption. *inspectdb* maps these columns to *DateTimeField* and if you enable timezone support, both MySQL and Django will attempt to convert the values from UTC to local time.

Row locking with `QuerySet.select_for_update()`

MySQL and MariaDB do not support some options to the `SELECT ... FOR UPDATE` statement. If `select_for_update()` is used with an unsupported option, then a *NotSupportedError* is raised.

Option	MariaDB	MySQL
SKIP LOCKED	X (≥ 10.6)	X ($\geq 8.0.1$)
NOWAIT	X	X ($\geq 8.0.1$)
OF		X ($\geq 8.0.1$)
NO KEY		

When using `select_for_update()` on MySQL, make sure you filter a queryset against at least a set of fields contained in unique constraints or only against fields covered by indexes. Otherwise, an exclusive write lock will be acquired over the full table for the duration of the transaction.

Automatic typecasting can cause unexpected results

When performing a query on a string type, but with an integer value, MySQL will coerce the types of all values in the table to an integer before performing the comparison. If your table contains the values `'abc'`, `'def'` and you query for `WHERE mycolumn=0`, both rows will match. Similarly, `WHERE mycolumn=1` will match the value `'abc1'`. Therefore, string type fields included in Django will always cast the value to a string before using it in a query.

If you implement custom model fields that inherit from `Field` directly, are overriding `get_prep_value()`, or use `RawSQL`, `extra()`, or `raw()`, you should ensure that you perform appropriate typecasting.

6.7.5 SQLite notes

Django supports SQLite 3.21.0 and later.

SQLite provides an excellent development alternative for applications that are predominantly read-only or require a smaller installation footprint. As with all database servers, though, there are some differences that are specific to SQLite that you should be aware of.

Substring matching and case sensitivity

For all SQLite versions, there is some slightly counter-intuitive behavior when attempting to match some types of strings. These are triggered when using the `icontains` or `contains` filters in Querysets. The behavior splits into two cases:

1. For substring matching, all matches are done case-insensitively. That is a filter such as `filter(name__contains="aa")` will match a name of `"Aabb"`.
2. For strings containing characters outside the ASCII range, all exact string matches are performed case-sensitively, even when the case-insensitive options are passed into the query. So the `icontains` filter will behave exactly the same as the `exact` filter in these cases.

Some possible workarounds for this are [documented at `sqlite.org`](#), but they aren't utilized by the default SQLite backend in Django, as incorporating them would be fairly difficult to do robustly. Thus, Django exposes the default SQLite behavior and you should be aware of this when doing case-insensitive or substring filtering.

Decimal handling

SQLite has no real decimal internal type. Decimal values are internally converted to the `REAL` data type (8-byte IEEE floating point number), as explained in the [SQLite datatypes documentation](#), so they don't support correctly-rounded decimal floating point arithmetic.

“Database is locked” errors

SQLite is meant to be a lightweight database, and thus can't support a high level of concurrency. `OperationalError: database is locked` errors indicate that your application is experiencing more concurrency than `sqlite` can handle in default configuration. This error means that one thread or process has an exclusive lock on the database connection and another thread timed out waiting for the lock to be released.

Python's SQLite wrapper has a default timeout value that determines how long the second thread is allowed to wait on the lock before it times out and raises the `OperationalError: database is locked` error.

If you're getting this error, you can solve it by:

- Switching to another database backend. At a certain point SQLite becomes too “lite” for real-world applications, and these sorts of concurrency errors indicate you've reached that point.
- Rewriting your code to reduce concurrency and ensure that database transactions are short-lived.
- Increase the default timeout value by setting the `timeout` database option:

```
"OPTIONS": {
    # ...
    "timeout": 20,
    # ...
}
```

This will make SQLite wait a bit longer before throwing “database is locked” errors; it won't really do anything to solve them.

`QuerySet.select_for_update()` not supported

SQLite does not support the `SELECT ... FOR UPDATE` syntax. Calling it will have no effect.

Isolation when using `QuerySet.iterator()`

There are special considerations described in [Isolation In SQLite](#) when modifying a table while iterating over it using `QuerySet.iterator()`. If a row is added, changed, or deleted within the loop, then that row may or may not appear, or may appear twice, in subsequent results fetched from the iterator. Your code must handle this.

Enabling JSON1 extension on SQLite

To use `JSONField` on SQLite, you need to enable the [JSON1 extension](#) on Python's `sqlite3` library. If the extension is not enabled on your installation, a system error (`fields.E180`) will be raised.

To enable the JSON1 extension you can follow the instruction on [the wiki page](#).

Note: The JSON1 extension is enabled by default on SQLite 3.38+.

6.7.6 Oracle notes

Django supports [Oracle Database Server](#) versions 19c and higher. Version 7.0 or higher of the `cx_Oracle` Python driver is required.

In order for the `python manage.py migrate` command to work, your Oracle database user must have privileges to run the following commands:

- `CREATE TABLE`
- `CREATE SEQUENCE`
- `CREATE PROCEDURE`
- `CREATE TRIGGER`

To run a project's test suite, the user usually needs these additional privileges:

- `CREATE USER`
- `ALTER USER`
- `DROP USER`
- `CREATE TABLESPACE`
- `DROP TABLESPACE`

- CREATE SESSION WITH ADMIN OPTION
- CREATE TABLE WITH ADMIN OPTION
- CREATE SEQUENCE WITH ADMIN OPTION
- CREATE PROCEDURE WITH ADMIN OPTION
- CREATE TRIGGER WITH ADMIN OPTION

While the `RESOURCE` role has the required `CREATE TABLE`, `CREATE SEQUENCE`, `CREATE PROCEDURE`, and `CREATE TRIGGER` privileges, and a user granted `RESOURCE WITH ADMIN OPTION` can grant `RESOURCE`, such a user cannot grant the individual privileges (e.g. `CREATE TABLE`), and thus `RESOURCE WITH ADMIN OPTION` is not usually sufficient for running tests.

Some test suites also create views or materialized views; to run these, the user also needs `CREATE VIEW WITH ADMIN OPTION` and `CREATE MATERIALIZED VIEW WITH ADMIN OPTION` privileges. In particular, this is needed for Django's own test suite.

All of these privileges are included in the `DBA` role, which is appropriate for use on a private developer's database.

The Oracle database backend uses the `SYS.DBMS_LOB` and `SYS.DBMS_RANDOM` packages, so your user will require execute permissions on it. It's normally accessible to all users by default, but in case it is not, you'll need to grant permissions like so:

```
GRANT EXECUTE ON SYS.DBMS_LOB TO user;
GRANT EXECUTE ON SYS.DBMS_RANDOM TO user;
```

Connecting to the database

To connect using the service name of your Oracle database, your `settings.py` file should look something like this:

```
DATABASES = {
    "default": {
        "ENGINE": "django.db.backends.oracle",
        "NAME": "xe",
        "USER": "a_user",
        "PASSWORD": "a_password",
        "HOST": "",
        "PORT": "",
    }
}
```

In this case, you should leave both `HOST` and `PORT` empty. However, if you don't use a `tnsnames.ora` file or a similar naming method and want to connect using the SID ("xe" in this example), then fill in both `HOST` and `PORT` like so:

```
DATABASES = {
    "default": {
        "ENGINE": "django.db.backends.oracle",
        "NAME": "xe",
        "USER": "a_user",
        "PASSWORD": "a_password",
        "HOST": "dbprod01ned.mycompany.com",
        "PORT": "1540",
    }
}
```

You should either supply both *HOST* and *PORT*, or leave both as empty strings. Django will use a different connect descriptor depending on that choice.

Full DSN and Easy Connect

A Full DSN or Easy Connect string can be used in *NAME* if both *HOST* and *PORT* are empty. This format is required when using RAC or pluggable databases without `tnsnames.ora`, for example.

Example of an Easy Connect string:

```
"NAME": "localhost:1521/orclpdb1"
```

Example of a full DSN string:

```
"NAME": (
    "(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=localhost)(PORT=1521))"
    "(CONNECT_DATA=(SERVICE_NAME=orclpdb1)))"
)
```

Threaded option

If you plan to run Django in a multithreaded environment (e.g. Apache using the default MPM module on any modern operating system), then you must set the `threaded` option of your Oracle database configuration to `True`:

```
"OPTIONS": {
    "threaded": True,
}
```

Failure to do this may result in crashes and other odd behavior.

INSERT ... RETURNING INTO

By default, the Oracle backend uses a `RETURNING INTO` clause to efficiently retrieve the value of an `AutoField` when inserting new rows. This behavior may result in a `DatabaseError` in certain unusual setups, such as when inserting into a remote table, or into a view with an `INSTEAD OF` trigger. The `RETURNING INTO` clause can be disabled by setting the `use_returning_into` option of the database configuration to `False`:

```
"OPTIONS": {
    "use_returning_into": False,
}
```

In this case, the Oracle backend will use a separate `SELECT` query to retrieve `AutoField` values.

Naming issues

Oracle imposes a name length limit of 30 characters. To accommodate this, the backend truncates database identifiers to fit, replacing the final four characters of the truncated name with a repeatable MD5 hash value. Additionally, the backend turns database identifiers to all-uppercase.

To prevent these transformations (this is usually required only when dealing with legacy databases or accessing tables which belong to other users), use a quoted name as the value for `db_table`:

```
class LegacyModel(models.Model):
    class Meta:
        db_table = '"name_left_in_lowercase"'

class ForeignModel(models.Model):
    class Meta:
        db_table = '"OTHER_USER"."NAME_ONLY_SEEMS_OVER_30"'
```

Quoted names can also be used with Django's other supported database backends; except for Oracle, however, the quotes have no effect.

When running `migrate`, an `ORA-06552` error may be encountered if certain Oracle keywords are used as the name of a model field or the value of a `db_column` option. Django quotes all identifiers used in queries to prevent most such problems, but this error can still occur when an Oracle datatype is used as a column name. In particular, take care to avoid using the names `date`, `timestamp`, `number` or `float` as a field name.

NULL and empty strings

Django generally prefers to use the empty string (`' '`) rather than `NULL`, but Oracle treats both identically. To get around this, the Oracle backend ignores an explicit `null` option on fields that have the empty string as a possible value and generates DDL as if `null=True`. When fetching from the database, it is assumed that a `NULL` value in one of these fields really means the empty string, and the data is silently converted to reflect this assumption.

TextField limitations

The Oracle backend stores `TextFields` as `NCLOB` columns. Oracle imposes some limitations on the usage of such LOB columns in general:

- LOB columns may not be used as primary keys.
- LOB columns may not be used in indexes.
- LOB columns may not be used in a `SELECT DISTINCT` list. This means that attempting to use the `QuerySet.distinct` method on a model that includes `TextField` columns will result in an `ORA-00932` error when run against Oracle. As a workaround, use the `QuerySet.defer` method in conjunction with `distinct()` to prevent `TextField` columns from being included in the `SELECT DISTINCT` list.

6.7.7 Subclassing the built-in database backends

Django comes with built-in database backends. You may subclass an existing database backends to modify its behavior, features, or configuration.

Consider, for example, that you need to change a single database feature. First, you have to create a new directory with a `base` module in it. For example:

```
mysite/
...
mydbengine/
    __init__.py
    base.py
```

The `base.py` module must contain a class named `DatabaseWrapper` that subclasses an existing engine from the `django.db.backends` module. Here's an example of subclassing the PostgreSQL engine to change a feature class `allows_group_by_selected_pks_on_model`:

Listing 10: `mysite/mydbengine/base.py`

```
from django.db.backends.postgresql import base, features
```

(continues on next page)

(continued from previous page)

```
class DatabaseFeatures(features.DatabaseFeatures):
    def allows_group_by_selected_pks_on_model(self, model):
        return True

class DatabaseWrapper(base.DatabaseWrapper):
    features_class = DatabaseFeatures
```

Finally, you must specify a *DATABASE-ENGINE* in your `settings.py` file:

```
DATABASES = {
    "default": {
        "ENGINE": "mydbengine",
        # ...
    },
}
```

You can see the current list of database engines by looking in [django/db/backends](#).

6.7.8 Using a 3rd-party database backend

In addition to the officially supported databases, there are backends provided by 3rd parties that allow you to use other databases with Django:

- [CockroachDB](#)
- [Firebird](#)
- [Google Cloud Spanner](#)
- [Microsoft SQL Server](#)
- [Snowflake](#)
- [TiDB](#)
- [YugabyteDB](#)

The Django versions and ORM features supported by these unofficial backends vary considerably. Queries regarding the specific capabilities of these unofficial backends, along with any support queries, should be directed to the support channels provided by each 3rd party project.

6.8 django-admin and manage.py

`django-admin` is Django's command-line utility for administrative tasks. This document outlines all it can do.

In addition, `manage.py` is automatically created in each Django project. It does the same thing as `django-admin` but also sets the `DJANGO_SETTINGS_MODULE` environment variable so that it points to your project's `settings.py` file.

The `django-admin` script should be on your system path if you installed Django via `pip`. If it's not in your path, ensure you have your virtual environment activated.

Generally, when working on a single Django project, it's easier to use `manage.py` than `django-admin`. If you need to switch between multiple Django settings files, use `django-admin` with `DJANGO_SETTINGS_MODULE` or the `--settings` command line option.

The command-line examples throughout this document use `django-admin` to be consistent, but any example can use `manage.py` or `python -m django` just as well.

6.8.1 Usage

```
$ django-admin <command> [options]
$ manage.py <command> [options]
$ python -m django <command> [options]
```

`command` should be one of the commands listed in this document. `options`, which is optional, should be zero or more of the options available for the given command.

Getting runtime help

`django-admin help`

Run `django-admin help` to display usage information and a list of the commands provided by each application.

Run `django-admin help --commands` to display a list of all available commands.

Run `django-admin help <command>` to display a description of the given command and a list of its available options.

App names

Many commands take a list of “app names.” An “app name” is the basename of the package containing your models. For example, if your `INSTALLED_APPS` contains the string `'mysite.blog'`, the app name is `blog`.

Determining the version

`django-admin version`

Run `django-admin version` to display the current Django version.

The output follows the schema described in [PEP 440](#):

```
1.4.dev17026
1.4a1
1.4
```

Displaying debug output

Use `--verbosity`, where it is supported, to specify the amount of notification and debug information that `django-admin` prints to the console.

6.8.2 Available commands

`check`

`django-admin check [app_label [app_label ...]]`

Uses the [system check framework](#) to inspect the entire Django project for common problems.

By default, all apps will be checked. You can check a subset of apps by providing a list of app labels as arguments:

```
django-admin check auth admin myapp
```

`--tag TAGS, -t TAGS`

The system check framework performs many different types of checks that are [categorized with tags](#). You can use these tags to restrict the checks performed to just those in a particular category. For example, to perform only models and compatibility checks, run:

```
django-admin check --tag models --tag compatibility
```

--database DATABASE

Specifies the database to run checks requiring database access:

```
django-admin check --database default --database other
```

By default, these checks will not be run.

--list-tags

Lists all available tags.

--deploy

Activates some additional checks that are only relevant in a deployment setting.

You can use this option in your local development environment, but since your local development settings module may not have many of your production settings, you will probably want to point the `check` command at a different settings module, either by setting the `DJANGO_SETTINGS_MODULE` environment variable, or by passing the `--settings` option:

```
django-admin check --deploy --settings=production_settings
```

Or you could run it directly on a production or staging deployment to verify that the correct settings are in use (omitting `--settings`). You could even make it part of your integration test suite.

--fail-level {CRITICAL,ERROR,WARNING,INFO,DEBUG}

Specifies the message level that will cause the command to exit with a non-zero status. Default is `ERROR`.

`compilemessages`

django-admin compilemessages

Compiles `.po` files created by `makemessages` to `.mo` files for use with the built-in gettext support. See [Internationalization and localization](#).

--locale LOCALE, -l LOCALE

Specifies the locale(s) to process. If not provided, all locales are processed.

--exclude EXCLUDE, -x EXCLUDE

Specifies the locale(s) to exclude from processing. If not provided, no locales are excluded.

--use-fuzzy, -f

Includes [fuzzy translations](#) into compiled files.

Example usage:

```
django-admin compilemessages --locale=pt_BR
django-admin compilemessages --locale=pt_BR --locale=fr -f
django-admin compilemessages -l pt_BR
django-admin compilemessages -l pt_BR -l fr --use-fuzzy
django-admin compilemessages --exclude=pt_BR
django-admin compilemessages --exclude=pt_BR --exclude=fr
django-admin compilemessages -x pt_BR
django-admin compilemessages -x pt_BR -x fr
```

--ignore PATTERN, -i PATTERN

Ignores directories matching the given [glob](#)-style pattern. Use multiple times to ignore more.

Example usage:

```
django-admin compilemessages --ignore=cache --ignore=outdated/*/locale
```

createcachetable

django-admin createcachetable

Creates the cache tables for use with the database cache backend using the information from your settings file. See [Django's cache framework](#) for more information.

--database DATABASE

Specifies the database in which the cache table(s) will be created. Defaults to `default`.

--dry-run

Prints the SQL that would be run without actually running it, so you can customize it or use the migrations framework.

dbshell

django-admin dbshell

Runs the command-line client for the database engine specified in your [ENGINE](#) setting, with the connection parameters specified in your [USER](#), [PASSWORD](#), etc., settings.

- For PostgreSQL, this runs the `psql` command-line client.
- For MySQL, this runs the `mysql` command-line client.
- For SQLite, this runs the `sqlite3` command-line client.
- For Oracle, this runs the `sqlplus` command-line client.

This command assumes the programs are on your PATH so that a call to the program name (`psql`, `mysql`, `sqlite3`, `sqlplus`) will find the program in the right place. There's no way to specify the location of the program manually.

--database DATABASE

Specifies the database onto which to open a shell. Defaults to `default`.

-- ARGUMENTS

Any arguments following a `--` divider will be passed on to the underlying command-line client. For example, with PostgreSQL you can use the `psql` command's `-c` flag to execute a raw SQL query directly:

```
$ django-admin dbshell -- -c 'select current_user'
current_user
-----
postgres
(1 row)
```

On MySQL/MariaDB, you can do this with the `mysql` command's `-e` flag:

```
$ django-admin dbshell -- -e "select user()"
+-----+
| user() |
+-----+
| djangonaut@localhost |
+-----+
```

Note: Be aware that not all options set in the *OPTIONS* part of your database configuration in *DATABASES* are passed to the command-line client, e.g. `'isolation_level'`.

`diffsettings`

`django-admin diffsettings`

Displays differences between the current settings file and Django's default settings (or another settings file specified by `--default`).

Settings that don't appear in the defaults are followed by `###`. For example, the default settings don't define `ROOT_URLCONF`, so `ROOT_URLCONF` is followed by `###` in the output of `diffsettings`.

--all

Displays all settings, even if they have Django's default value. Such settings are prefixed by `###`.

--default MODULE

The settings module to compare the current settings against. Leave empty to compare against Django's default settings.

--output {hash,unified}

Specifies the output format. Available values are `hash` and `unified`. `hash` is the default mode that displays the output that's described above. `unified` displays the output similar to `diff -u`. Default settings are prefixed with a minus sign, followed by the changed setting prefixed with a plus sign.

`dumpdata`

```
django-admin dumpdata [app_label[.ModelName] [app_label[.ModelName] ...]]
```

Outputs to standard output all data in the database associated with the named application(s).

If no application name is provided, all installed applications will be dumped.

The output of `dumpdata` can be used as input for `loaddata`.

When result of `dumpdata` is saved as a file, it can serve as a `fixture` for `tests` or as an `initial data`.

Note that `dumpdata` uses the default manager on the model for selecting the records to dump. If you're using a `custom manager` as the default manager and it filters some of the available records, not all of the objects will be dumped.

--all, -a

Uses Django's base manager, dumping records which might otherwise be filtered or modified by a custom manager.

--format FORMAT

Specifies the serialization format of the output. Defaults to JSON. Supported formats are listed in [Serialization formats](#).

--indent INDENT

Specifies the number of indentation spaces to use in the output. Defaults to `None` which displays all data on single line.

--exclude EXCLUDE, **-e** EXCLUDE

Prevents specific applications or models (specified in the form of `app_label.ModelName`) from being dumped. If you specify a model name, then only that model will be excluded, rather than the entire application. You can also mix application names and model names.

If you want to exclude multiple applications, pass `--exclude` more than once:

```
django-admin dumpdata --exclude=auth --exclude=contenttypes
```

--database DATABASE

Specifies the database from which data will be dumped. Defaults to `default`.

--natural-foreign

Uses the `natural_key()` model method to serialize any foreign key and many-to-many relationship to objects of the type that defines the method. If you're dumping `contrib.auth.Permission` objects or `contrib.contenttypes.ContentType` objects, you should probably use this flag. See the [natural keys](#) documentation for more details on this and the next option.

--natural-primary

Omits the primary key in the serialized data of this object since it can be calculated during deserialization.

--pks PRIMARY_KEYS

Outputs only the objects specified by a comma separated list of primary keys. This is only available when dumping one model. By default, all the records of the model are output.

--output OUTPUT, -o OUTPUT

Specifies a file to write the serialized data to. By default, the data goes to standard output.

When this option is set and `--verbosity` is greater than 0 (the default), a progress bar is shown in the terminal.

Fixtures compression

The output file can be compressed with one of the `bz2`, `gz`, `lzma`, or `xz` formats by ending the filename with the corresponding extension. For example, to output the data as a compressed JSON file:

```
django-admin dumpdata -o mydata.json.gz
```

flush

django-admin flush

Removes all data from the database and re-executes any post-synchronization handlers. The table of which migrations have been applied is not cleared.

If you would rather start from an empty database and rerun all migrations, you should drop and recreate the database and then run *migrate* instead.

`--noinput, --no-input`

Suppresses all user prompts.

`--database DATABASE`

Specifies the database to flush. Defaults to `default`.

`inspectdb`

`django-admin inspectdb [table [table ...]]`

Introspects the database tables in the database pointed-to by the *NAME* setting and outputs a Django model module (a `models.py` file) to standard output.

You may choose what tables or views to inspect by passing their names as arguments. If no arguments are provided, models are created for views only if the `--include-views` option is used. Models for partition tables are created on PostgreSQL if the `--include-partitions` option is used.

Use this if you have a legacy database with which you'd like to use Django. The script will inspect the database and create a model for each table within it.

As you might expect, the created models will have an attribute for every field in the table. Note that `inspectdb` has a few special cases in its field-name output:

- If `inspectdb` cannot map a column's type to a model field type, it'll use `TextField` and will insert the Python comment `'This field type is a guess.'` next to the field in the generated model. The recognized fields may depend on apps listed in *INSTALLED_APPS*. For example, *django.contrib.postgres* adds recognition for several PostgreSQL-specific field types.
- If the database column name is a Python reserved word (such as `'pass'`, `'class'` or `'for'`), `inspectdb` will append `'_field'` to the attribute name. For example, if a table has a column `'for'`, the generated model will have a field `'for_field'`, with the `db_column` attribute set to `'for'`. `inspectdb` will insert the Python comment `'Field renamed because it was a Python reserved word.'` next to the field.

This feature is meant as a shortcut, not as definitive model generation. After you run it, you'll want to look over the generated models yourself to make customizations. In particular, you'll need to rearrange models' order, so that models that refer to other models are ordered properly.

Django doesn't create database defaults when a *default* is specified on a model field. Similarly, database defaults aren't translated to model field defaults or detected in any fashion by `inspectdb`.

By default, `inspectdb` creates unmanaged models. That is, `managed = False` in the model's `Meta` class tells Django not to manage each table's creation, modification, and deletion. If you do want to allow Django to manage the table's lifecycle, you'll need to change the *managed* option to `True` (or remove it because `True` is its default value).

Database-specific notes

Oracle

- Models are created for materialized views if `--include-views` is used.

PostgreSQL

- Models are created for foreign tables.
- Models are created for materialized views if `--include-views` is used.
- Models are created for partition tables if `--include-partitions` is used.

`--database DATABASE`

Specifies the database to introspect. Defaults to `default`.

`--include-partitions`

If this option is provided, models are also created for partitions.

Only support for PostgreSQL is implemented.

`--include-views`

If this option is provided, models are also created for database views.

loaddata

`django-admin loaddata fixture [fixture ...]`

Searches for and loads the contents of the named `fixture` into the database.

`--database DATABASE`

Specifies the database into which the data will be loaded. Defaults to `default`.

`--ignorenonexistent, -i`

Ignores fields and models that may have been removed since the fixture was originally generated.

`--app APP_LABEL`

Specifies a single app to look for fixtures in rather than looking in all apps.

`--format FORMAT`

Specifies the `serialization format` (e.g., `json` or `xml`) for fixtures read from `stdin`.

--exclude EXCLUDE, **-e** EXCLUDE

Excludes loading the fixtures from the given applications and/or models (in the form of `app_label` or `app_label.ModelName`). Use the option multiple times to exclude more than one app or model.

Loading fixtures from `stdin`

You can use a dash as the fixture name to load input from `sys.stdin`. For example:

```
django-admin loaddata --format=json -
```

When reading from `stdin`, the `--format` option is required to specify the [serialization format](#) of the input (e.g., `json` or `xml`).

Loading from `stdin` is useful with standard input and output redirections. For example:

```
django-admin dumpdata --format=json --database=test app_label.ModelName | django-admin loaddata --
↪format=json --database=prod -
```

The `dumpdata` command can be used to generate input for `loaddata`.

See also:

For more detail about fixtures see the [Fixtures](#) topic.

`makemessages`

`django-admin makemessages`

Runs over the entire source tree of the current directory and pulls out all strings marked for translation. It creates (or updates) a message file in the `conf/locale` (in the Django tree) or `locale` (for project and application) directory. After making changes to the messages files you need to compile them with `compilemessages` for use with the builtin gettext support. See the [i18n documentation](#) for details.

This command doesn't require configured settings. However, when settings aren't configured, the command can't ignore the `MEDIA_ROOT` and `STATIC_ROOT` directories or include `LOCALE_PATHS`.

--all, **-a**

Updates the message files for all available languages.

--extension EXTENSIONS, **-e** EXTENSIONS

Specifies a list of file extensions to examine (default: `html`, `txt`, `py` or `js` if `--domain` is `js`).

Example usage:

```
django-admin makemessages --locale=de --extension xhtml
```

Separate multiple extensions with commas or use `-e` or `--extension` multiple times:

```
django-admin makemessages --locale=de --extension=html,txt --extension xml
```

--locale LOCALE, **-l** LOCALE

Specifies the locale(s) to process.

--exclude EXCLUDE, **-x** EXCLUDE

Specifies the locale(s) to exclude from processing. If not provided, no locales are excluded.

Example usage:

```
django-admin makemessages --locale=pt_BR
django-admin makemessages --locale=pt_BR --locale=fr
django-admin makemessages -l pt_BR
django-admin makemessages -l pt_BR -l fr
django-admin makemessages --exclude=pt_BR
django-admin makemessages --exclude=pt_BR --exclude=fr
django-admin makemessages -x pt_BR
django-admin makemessages -x pt_BR -x fr
```

--domain DOMAIN, **-d** DOMAIN

Specifies the domain of the messages files. Supported options are:

- `django` for all `*.py`, `*.html` and `*.txt` files (default)
- `djangojs` for `*.js` files

--symlinks, **-s**

Follows symlinks to directories when looking for new translation strings.

Example usage:

```
django-admin makemessages --locale=de --symlinks
```

--ignore PATTERN, **-i** PATTERN

Ignores files or directories matching the given `glob`-style pattern. Use multiple times to ignore more.

These patterns are used by default: `'CVS'`, `'.*'`, `'*~'`, `'*.pyc'`.

Example usage:

```
django-admin makemessages --locale=en_US --ignore=apps/* --ignore=secret/*.html
```

--no-default-ignore

Disables the default values of `--ignore`.

--no-wrap

Disables breaking long message lines into several lines in language files.

--no-location

Suppresses writing ‘`#: filename:line`’ comment lines in language files. Using this option makes it harder for technically skilled translators to understand each message’s context.

--add-location [{full,file,never}]

Controls `#: filename:line` comment lines in language files. If the option is:

- **full** (the default if not given): the lines include both file name and line number.
- **file**: the line number is omitted.
- **never**: the lines are suppressed (same as `--no-location`).

Requires `gettext` 0.19 or newer.

--keep-pot

Prevents deleting the temporary `.pot` files generated before creating the `.po` file. This is useful for debugging errors which may prevent the final language files from being created.

See also:

See [Customizing the makemessages command](#) for instructions on how to customize the keywords that *makemessages* passes to `xgettext`.

makemigrations

```
django-admin makemigrations [app_label [app_label ...]]
```

Creates new migrations based on the changes detected to your models. Migrations, their relationship with apps and more are covered in depth in [the migrations documentation](#).

Providing one or more app names as arguments will limit the migrations created to the app(s) specified and any dependencies needed (the table at the other end of a `ForeignKey`, for example).

To add migrations to an app that doesn’t have a `migrations` directory, run `makemigrations` with the app’s `app_label`.

--noinput, --no-input

Suppresses all user prompts. If a suppressed prompt cannot be resolved automatically, the command will exit with error code 3.

--empty

Outputs an empty migration for the specified apps, for manual editing. This is for advanced users and should not be used unless you are familiar with the migration format, migration operations, and the dependencies between your migrations.

--dry-run

Shows what migrations would be made without actually writing any migrations files to disk. Using this option along with **--verbosity 3** will also show the complete migrations files that would be written.

--merge

Enables fixing of migration conflicts.

--name NAME, -n NAME

Allows naming the generated migration(s) instead of using a generated name. The name must be a valid Python [identifier](#).

--no-header

Generate migration files without Django version and timestamp header.

--check

Makes `makemigrations` exit with a non-zero status when model changes without migrations are detected.

In older versions, the missing migrations were also created when using the **--check** option.

--scriptable

Diverts log output and input prompts to `stderr`, writing only paths of generated migration files to `stdout`.

--update

Merges model changes into the latest migration and optimize the resulting operations.

The updated migration will have a generated name. In order to preserve the previous name, set it using

--name.

`migrate`

`django-admin migrate [app_label] [migration_name]`

Synchronizes the database state with the current set of models and migrations. Migrations, their relationship with apps and more are covered in depth in [the migrations documentation](#).

The behavior of this command changes depending on the arguments provided:

- No arguments: All apps have all of their migrations run.
- `<app_label>`: The specified app has its migrations run, up to the most recent migration. This may involve running other apps' migrations too, due to dependencies.
- `<app_label> <migrationname>`: Brings the database schema to a state where the named migration is applied, but no later migrations in the same app are applied. This may involve unapplying migrations if you have previously migrated past the named migration. You can use a prefix of the migration name, e.g. `0001`, as long as it's unique for the given app name. Use the name `zero` to migrate all the way back i.e. to revert all applied migrations for an app.

Warning: When unapplying migrations, all dependent migrations will also be unapplied, regardless of `<app_label>`. You can use `--plan` to check which migrations will be unapplied.

`--database DATABASE`

Specifies the database to migrate. Defaults to `default`.

`--fake`

Marks the migrations up to the target one (following the rules above) as applied, but without actually running the SQL to change your database schema.

This is intended for advanced users to manipulate the current migration state directly if they're manually applying changes; be warned that using `--fake` runs the risk of putting the migration state table into a state where manual recovery will be needed to make migrations run correctly.

`--fake-initial`

Allows Django to skip an app's initial migration if all database tables with the names of all models created by all `CreateModel` operations in that migration already exist. This option is intended for use when first running migrations against a database that preexisted the use of migrations. This option does not, however, check for matching database schema beyond matching table names and so is only safe to use if you are confident that your existing schema matches what is recorded in your initial migration.

`--plan`

Shows the migration operations that will be performed for the given `migrate` command.

--run-syncdb

Allows creating tables for apps without migrations. While this isn't recommended, the migrations framework is sometimes too slow on large projects with hundreds of models.

--noinput, --no-input

Suppresses all user prompts. An example prompt is asking about removing stale content types.

--check

Makes `migrate` exit with a non-zero status when unapplied migrations are detected.

--prune

Deletes nonexistent migrations from the `django_migrations` table. This is useful when migration files replaced by a squashed migration have been removed. See [Squashing migrations](#) for more details.

optimizemigration

django-admin optimizemigration app_label migration_name

Optimizes the operations for the named migration and overrides the existing file. If the migration contains functions that must be manually copied, the command creates a new migration file suffixed with `_optimized` that is meant to replace the named migration.

--check

Makes `optimizemigration` exit with a non-zero status when a migration can be optimized.

runserver

django-admin runserver [addrport]

Starts a lightweight development web server on the local machine. By default, the server runs on port 8000 on the IP address `127.0.0.1`. You can pass in an IP address and port number explicitly.

If you run this script as a user with normal privileges (recommended), you might not have access to start a port on a low port number. Low port numbers are reserved for the superuser (root).

This server uses the WSGI application object specified by the `WSGI_APPLICATION` setting.

DO NOT USE THIS SERVER IN A PRODUCTION SETTING. It has not gone through security audits or performance tests. (And that's how it's gonna stay. We're in the business of making web frameworks, not web servers, so improving this server to be able to handle a production environment is outside the scope of Django.)

The development server automatically reloads Python code for each request, as needed. You don't need to restart the server for code changes to take effect. However, some actions like adding files don't trigger a restart, so you'll have to restart the server in these cases.

If you're using Linux or MacOS and install both `pywatchman` and the `Watchman` service, kernel signals will be used to autoreload the server (rather than polling file modification timestamps each second). This offers better performance on large projects, reduced response time after code changes, more robust change detection, and a reduction in power usage. Django supports `pywatchman` 1.2.0 and higher.

Large directories with many files may cause performance issues

When using `Watchman` with a project that includes large non-Python directories like `node_modules`, it's advisable to ignore this directory for optimal performance. See the [watchman documentation](#) for information on how to do this.

Watchman timeout

`DJANGO_WATCHMAN_TIMEOUT`

The default timeout of `Watchman` client is 5 seconds. You can change it by setting the `DJANGO_WATCHMAN_TIMEOUT` environment variable.

When you start the server, and each time you change Python code while the server is running, the system check framework will check your entire Django project for some common errors (see the `check` command). If any errors are found, they will be printed to standard output. You can use the `--skip-checks` option to skip running system checks.

You can run as many concurrent servers as you want, as long as they're on separate ports by executing `django-admin runserver` more than once.

Note that the default IP address, `127.0.0.1`, is not accessible from other machines on your network. To make your development server viewable to other machines on the network, use its own IP address (e.g. `192.168.2.1`), `0` (shortcut for `0.0.0.0`), `0.0.0.0`, or `::` (with IPv6 enabled).

You can provide an IPv6 address surrounded by brackets (e.g. `[200a::1]:8000`). This will automatically enable IPv6 support.

A hostname containing ASCII-only characters can also be used.

If the `staticfiles` contrib app is enabled (default in new projects) the `runserver` command will be overridden with its own `runserver` command.

Logging of each request and response of the server is sent to the `django.server` logger.

`--noreload`

Disables the auto-reloader. This means any Python code changes you make while the server is running will not take effect if the particular Python modules have already been loaded into memory.

`--nothreading`

Disables use of threading in the development server. The server is multithreaded by default.

--ipv6, -6

Uses IPv6 for the development server. This changes the default IP address from 127.0.0.1 to ::1.

Examples of using different ports and addresses

Port 8000 on IP address 127.0.0.1:

```
django-admin runserver
```

Port 8000 on IP address 1.2.3.4:

```
django-admin runserver 1.2.3.4:8000
```

Port 7000 on IP address 127.0.0.1:

```
django-admin runserver 7000
```

Port 7000 on IP address 1.2.3.4:

```
django-admin runserver 1.2.3.4:7000
```

Port 8000 on IPv6 address ::1:

```
django-admin runserver -6
```

Port 7000 on IPv6 address ::1:

```
django-admin runserver -6 7000
```

Port 7000 on IPv6 address 2001:0db8:1234:5678::9:

```
django-admin runserver [2001:0db8:1234:5678::9]:7000
```

Port 8000 on IPv4 address of host localhost:

```
django-admin runserver localhost:8000
```

Port 8000 on IPv6 address of host localhost:

```
django-admin runserver -6 localhost:8000
```

Serving static files with the development server

By default, the development server doesn't serve any static files for your site (such as CSS files, images, things under `MEDIA_URL` and so forth). If you want to configure Django to serve static media, read [How to manage static files](#) (e.g. images, JavaScript, CSS).

Serving with ASGI in development

Django's `runserver` command provides a WSGI server. In order to run under ASGI you will need to use an [ASGI server](#). The Django Daphne project provides [Integration with runserver](#) that you can use.

`sendtestemail`

```
django-admin sendtestemail [email [email ...]]
```

Sends a test email (to confirm email sending through Django is working) to the recipient(s) specified. For example:

```
django-admin sendtestemail foo@example.com bar@example.com
```

There are a couple of options, and you may use any combination of them together:

`--managers`

Mails the email addresses specified in `MANAGERS` using `mail_managers()`.

`--admins`

Mails the email addresses specified in `ADMINS` using `mail_admins()`.

`shell`

```
django-admin shell
```

Starts the Python interactive interpreter.

```
--interface {ipython,bpython,python}, -i {ipython,bpython,python}
```

Specifies the shell to use. By default, Django will use `IPython` or `bpython` if either is installed. If both are installed, specify which one you want like so:

IPython:

```
django-admin shell -i ipython
```

bpython:

```
django-admin shell -i bpython
```

If you have a “rich” shell installed but want to force use of the “plain” Python interpreter, use `python` as the interface name, like so:

```
django-admin shell -i python
```

--nostartup

Disables reading the startup script for the “plain” Python interpreter. By default, the script pointed to by the `PYTHONSTARTUP` environment variable or the `~/.pythonrc.py` script is read.

--command COMMAND, **-c** COMMAND

Lets you pass a command as a string to execute it as Django, like so:

```
django-admin shell --command="import django; print(django.__version__)"
```

You can also pass code in on standard input to execute it. For example:

```
$ django-admin shell <<EOF
> import django
> print(django.__version__)
> EOF
```

On Windows, the REPL is output due to implementation limits of `select.select()` on that platform.

showmigrations

```
django-admin showmigrations [app_label [app_label ...]]
```

Shows all migrations in a project. You can choose from one of two formats:

--list, **-l**

Lists all of the apps Django knows about, the migrations available for each app, and whether or not each migration is applied (marked by an [X] next to the migration name). For a `--verbosity` of 2 and above, the applied datetimes are also shown.

Apps without migrations are also listed, but have (no migrations) printed under them.

This is the default output format.

--plan, **-p**

Shows the migration plan Django will follow to apply migrations. Like `--list`, applied migrations are marked by an [X]. For a `--verbosity` of 2 and above, all dependencies of a migration will also be shown.

`app_labels` arguments limit the output, however, dependencies of provided apps may also be included.

--database DATABASE

Specifies the database to examine. Defaults to `default`.

`sqlflush`

django-admin sqlflush

Prints the SQL statements that would be executed for the *flush* command.

--database DATABASE

Specifies the database for which to print the SQL. Defaults to `default`.

`sqlmigrate`

django-admin sqlmigrate app_label migration_name

Prints the SQL for the named migration. This requires an active database connection, which it will use to resolve constraint names; this means you must generate the SQL against a copy of the database you wish to later apply it on.

Note that `sqlmigrate` doesn't colorize its output.

--backwards

Generates the SQL for unapplying the migration. By default, the SQL created is for running the migration in the forwards direction.

--database DATABASE

Specifies the database for which to generate the SQL. Defaults to `default`.

`sqlsequencereset`

django-admin sqlsequencereset app_label [app_label ...]

Prints the SQL statements for resetting sequences for the given app name(s).

Sequences are indexes used by some database engines to track the next available number for automatically incremented fields.

Use this command to generate SQL which will fix cases where a sequence is out of sync with its automatically incremented field data.

--database DATABASE

Specifies the database for which to print the SQL. Defaults to `default`.

squashmigrations

```
django-admin squashmigrations app_label [start_migration_name] migration_name
```

Squashes the migrations for `app_label` up to and including `migration_name` down into fewer migrations, if possible. The resulting squashed migrations can live alongside the unsquashed ones safely. For more information, please read [Squashing migrations](#).

When `start_migration_name` is given, Django will only include migrations starting from and including this migration. This helps to mitigate the squashing limitation of *RunPython* and *django.db.migrations.operations.RunSQL* migration operations.

--no-optimize

Disables the optimizer when generating a squashed migration. By default, Django will try to optimize the operations in your migrations to reduce the size of the resulting file. Use this option if this process is failing or creating incorrect migrations, though please also file a Django bug report about the behavior, as optimization is meant to be safe.

--noinput, --no-input

Suppresses all user prompts.

--squashed-name SQUASHED_NAME

Sets the name of the squashed migration. When omitted, the name is based on the first and last migration, with `_squashed_` in between.

--no-header

Generate squashed migration file without Django version and timestamp header.

startapp

```
django-admin startapp name [directory]
```

Creates a Django app directory structure for the given app name in the current directory or the given destination.

By default, [the new directory](#) contains a `models.py` file and other app template files. If only the app name is given, the app directory will be created in the current working directory.

If the optional destination is provided, Django will use that existing directory rather than creating a new one. You can use `‘.’` to denote the current working directory.

For example:

```
django-admin startapp myapp /Users/jezdez/Code/myapp
```

--template TEMPLATE

Provides the path to a directory with a custom app template file, or a path to an uncompressed archive (`.tar`) or a compressed archive (`.tar.gz`, `.tar.bz2`, `.tar.xz`, `.tar.lzma`, `.tgz`, `.tbz2`, `.txz`, `.tlz`, `.zip`) containing the app template files.

For example, this would look for an app template in the given directory when creating the `myapp` app:

```
django-admin startapp --template=/Users/jezdez/Code/my_app_template myapp
```

Django will also accept URLs (`http`, `https`, `ftp`) to compressed archives with the app template files, downloading and extracting them on the fly.

For example, taking advantage of GitHub's feature to expose repositories as zip files, you can use a URL like:

```
django-admin startapp --template=https://github.com/githubuser/django-app-template/archive/main.  
↪zip myapp
```

--extension EXTENSIONS, **-e** EXTENSIONS

Specifies which file extensions in the app template should be rendered with the template engine. Defaults to `py`.

--name FILES, **-n** FILES

Specifies which files in the app template (in addition to those matching `--extension`) should be rendered with the template engine. Defaults to an empty list.

--exclude DIRECTORIES, **-x** DIRECTORIES

Specifies which directories in the app template should be excluded, in addition to `.git` and `__pycache__`. If this option is not provided, directories named `__pycache__` or starting with `.` will be excluded.

The *template context* used for all matching files is:

- Any option passed to the `startapp` command (among the command's supported options)
- `app_name` –the app name as passed to the command
- `app_directory` –the full path of the newly created app
- `camel_case_app_name` –the app name in camel case format
- `docs_version` –the version of the documentation: `'dev'` or `'1.x'`
- `django_version` –the version of Django, e.g. `'2.0.3'`

Warning: When the app template files are rendered with the Django template engine (by default all `*.py` files), Django will also replace all stray template variables contained. For example, if one of the

Python files contains a docstring explaining a particular feature related to template rendering, it might result in an incorrect example.

To work around this problem, you can use the `templatetag` template tag to “escape” the various parts of the template syntax.

In addition, to allow Python template files that contain Django template language syntax while also preventing packaging systems from trying to byte-compile invalid `*.py` files, template files ending with `.py-tpl` will be renamed to `.py`.

Warning: The contents of custom app (or project) templates should always be audited before use: Such templates define code that will become part of your project, and this means that such code will be trusted as much as any app you install, or code you write yourself. Further, even rendering the templates is, effectively, executing code that was provided as input to the management command. The Django template language may provide wide access into the system, so make sure any custom template you use is worthy of your trust.

`startproject`

`django-admin startproject name [directory]`

Creates a Django project directory structure for the given project name in the current directory or the given destination.

By default, the new `directory` contains `manage.py` and a project package (containing a `settings.py` and other files).

If only the project name is given, both the project directory and project package will be named `<projectname>` and the project directory will be created in the current working directory.

If the optional destination is provided, Django will use that existing directory as the project directory, and create `manage.py` and the project package within it. Use `‘.’` to denote the current working directory.

For example:

```
django-admin startproject myproject /Users/jezdez/Code/myproject_repo
```

`--template TEMPLATE`

Specifies a directory, file path, or URL of a custom project template. See the `startapp --template` documentation for examples and usage.

`--extension EXTENSIONS, -e EXTENSIONS`

Specifies which file extensions in the project template should be rendered with the template engine. Defaults to `py`.

--name FILES, **-n** FILES

Specifies which files in the project template (in addition to those matching **--extension**) should be rendered with the template engine. Defaults to an empty list.

--exclude DIRECTORIES, **-x** DIRECTORIES

Specifies which directories in the project template should be excluded, in addition to `.git` and `__pycache__`. If this option is not provided, directories named `__pycache__` or starting with `.` will be excluded.

The *template context* used is:

- Any option passed to the `startproject` command (among the command's supported options)
- `project_name` –the project name as passed to the command
- `project_directory` –the full path of the newly created project
- `secret_key` –a random key for the *SECRET_KEY* setting
- `docs_version` –the version of the documentation: `'dev'` or `'1.x'`
- `django_version` –the version of Django, e.g. `'2.0.3'`

Please also see the *rendering warning* and *trusted code warning* as mentioned for *startapp*.

test

django-admin test [test_label [test_label ...]]

Runs tests for all installed apps. See *Testing in Django* for more information.

--failfast

Stops running tests and reports the failure immediately after a test fails.

--testrunner TESTRUNNER

Controls the test runner class that is used to execute tests. This value overrides the value provided by the *TEST_RUNNER* setting.

--noinput, **--no-input**

Suppresses all user prompts. A typical prompt is a warning about deleting an existing test database.

Test runner options

The `test` command receives options on behalf of the specified `--testrunner`. These are the options of the default test runner: `DiscoverRunner`.

`--keepdb`

Preserves the test database between test runs. This has the advantage of skipping both the create and destroy actions which can greatly decrease the time to run tests, especially those in a large test suite. If the test database does not exist, it will be created on the first run and then preserved for each subsequent run. Unless the `MIGRATE` test setting is `False`, any unapplied migrations will also be applied to the test database before running the test suite.

`--shuffle [SEED]`

Randomizes the order of tests before running them. This can help detect tests that aren't properly isolated. The test order generated by this option is a deterministic function of the integer seed given. When no seed is passed, a seed is chosen randomly and printed to the console. To repeat a particular test order, pass a seed. The test orders generated by this option preserve Django's [guarantees on test order](#). They also keep tests grouped by test case class.

The shuffled orderings also have a special consistency property useful when narrowing down isolation issues. Namely, for a given seed and when running a subset of tests, the new order will be the original shuffling restricted to the smaller set. Similarly, when adding tests while keeping the seed the same, the order of the original tests will be the same in the new order.

`--reverse, -r`

Sorts test cases in the opposite execution order. This may help in debugging the side effects of tests that aren't properly isolated. [Grouping by test class](#) is preserved when using this option. This can be used in conjunction with `--shuffle` to reverse the order for a particular seed.

`--debug-mode`

Sets the `DEBUG` setting to `True` prior to running tests. This may help troubleshoot test failures.

`--debug-sql, -d`

Enables [SQL logging](#) for failing tests. If `--verbosity` is 2, then queries in passing tests are also output.

`--parallel [N]`

`DJANGO_TEST_PROCESSES`

Runs tests in separate parallel processes. Since modern processors have multiple cores, this allows running tests significantly faster.

Using `--parallel` without a value, or with the value `auto`, runs one test process per core according to `multiprocessing.cpu_count()`. You can override this by passing the desired number of processes, e.g. `--parallel 4`, or by setting the `DJANGO_TEST_PROCESSES` environment variable.

Django distributes test cases —`unittest.TestCase` subclasses — to subprocesses. If there are fewer test cases than configured processes, Django will reduce the number of processes accordingly.

Each process gets its own database. You must ensure that different test cases don't access the same resources. For instance, test cases that touch the filesystem should create a temporary directory for their own use.

Note: If you have test classes that cannot be run in parallel, you can use `SerializeMixin` to run them sequentially. See [Enforce running test classes sequentially](#).

This option requires the third-party `tblib` package to display tracebacks correctly:

```
$ python -m pip install tblib
```

This feature isn't available on Windows. It doesn't work with the Oracle database backend either.

If you want to use `pdb` while debugging tests, you must disable parallel execution (`--parallel=1`). You'll see something like `bdb.BdbQuit` if you don't.

Warning: When test parallelization is enabled and a test fails, Django may be unable to display the exception traceback. This can make debugging difficult. If you encounter this problem, run the affected test without parallelization to see the traceback of the failure.

This is a known limitation. It arises from the need to serialize objects in order to exchange them between processes. See [What can be pickled and unpickled?](#) for details.

--tag TAGS

Runs only tests [marked with the specified tags](#). May be specified multiple times and combined with `test --exclude-tag`.

Tests that fail to load are always considered matching.

--exclude-tag EXCLUDE_TAGS

Excludes tests [marked with the specified tags](#). May be specified multiple times and combined with `test --tag`.

-k TEST_NAME_PATTERNS

Runs test methods and classes matching test name patterns, in the same way as `unittest's -k option`. Can be specified multiple times.

--pdb

Spawns a `pdb` debugger at each test error or failure. If you have it installed, `ipdb` is used instead.

--buffer, -b

Discards output (`stdout` and `stderr`) for passing tests, in the same way as `unittest`'s `--buffer` option.

--no-faulthandler

Django automatically calls `faulthandler.enable()` when starting the tests, which allows it to print a trace-back if the interpreter crashes. Pass `--no-faulthandler` to disable this behavior.

--timing

Outputs timings, including database setup and total run time.

testserver

django-admin testserver [fixture [fixture ...]]

Runs a Django development server (as in `runserver`) using data from the given fixture(s).

For example, this command:

```
django-admin testserver mydata.json
```

...would perform the following steps:

1. Create a test database, as described in [The test database](#).
2. Populate the test database with fixture data from the given fixtures. (For more on fixtures, see the documentation for `loaddata` above.)
3. Runs the Django development server (as in `runserver`), pointed at this newly created test database instead of your production database.

This is useful in a number of ways:

- When you're writing [unit tests](#) of how your views act with certain fixture data, you can use `testserver` to interact with the views in a web browser, manually.
- Let's say you're developing your Django application and have a “pristine” copy of a database that you'd like to interact with. You can dump your database to a [fixture](#) (using the `dumpdata` command, explained above), then use `testserver` to run your web application with that data. With this arrangement, you have the flexibility of messing up your data in any way, knowing that whatever data changes you're making are only being made to a test database.

Note that this server does not automatically detect changes to your Python source code (as `runserver` does). It does, however, detect changes to templates.

--addrport ADDRPORT

Specifies a different port, or IP address and port, from the default of `127.0.0.1:8000`. This value follows exactly the same format and serves exactly the same function as the argument to the `runserver` command.

Examples:

To run the test server on port 7000 with `fixture1` and `fixture2`:

```
django-admin testserver --addrport 7000 fixture1 fixture2
django-admin testserver fixture1 fixture2 --addrport 7000
```

(The above statements are equivalent. We include both of them to demonstrate that it doesn't matter whether the options come before or after the fixture arguments.)

To run on 1.2.3.4:7000 with a `test` fixture:

```
django-admin testserver --addrport 1.2.3.4:7000 test
```

`--noinput`, `--no-input`

Suppresses all user prompts. A typical prompt is a warning about deleting an existing test database.

6.8.3 Commands provided by applications

Some commands are only available when the `django.contrib` application that implements them has been *enabled*. This section describes them grouped by their application.

`django.contrib.auth`

`changepassword`

`django-admin changepassword [<username>]`

This command is only available if Django's [authentication system](#) (`django.contrib.auth`) is installed.

Allows changing a user's password. It prompts you to enter a new password twice for the given user. If the entries are identical, this immediately becomes the new password. If you do not supply a user, the command will attempt to change the password whose username matches the current user.

`--database DATABASE`

Specifies the database to query for the user. Defaults to `default`.

Example usage:

```
django-admin changepassword ringo
```

`createsuperuser`

`django-admin createsuperuser`

`DJANGO_SUPERUSER_PASSWORD`

This command is only available if Django's [authentication system](#) (`django.contrib.auth`) is installed.

Creates a superuser account (a user who has all permissions). This is useful if you need to create an initial superuser account or if you need to programmatically generate superuser accounts for your site(s).

When run interactively, this command will prompt for a password for the new superuser account. When run non-interactively, you can provide a password by setting the `DJANGO_SUPERUSER_PASSWORD` environment variable. Otherwise, no password will be set, and the superuser account will not be able to log in until a password has been manually set for it.

In non-interactive mode, the `USERNAME_FIELD` and required fields (listed in `REQUIRED_FIELDS`) fall back to `DJANGO_SUPERUSER_<uppercase_field_name>` environment variables, unless they are overridden by a command line argument. For example, to provide an `email` field, you can use `DJANGO_SUPERUSER_EMAIL` environment variable.

`--noinput, --no-input`

Suppresses all user prompts. If a suppressed prompt cannot be resolved automatically, the command will exit with error code 1.

`--username USERNAME`

`--email EMAIL`

The username and email address for the new account can be supplied by using the `--username` and `--email` arguments on the command line. If either of those is not supplied, `createsuperuser` will prompt for it when running interactively.

`--database DATABASE`

Specifies the database into which the superuser object will be saved.

You can subclass the management command and override `get_input_data()` if you want to customize data input and validation. Consult the source code for details on the existing implementation and the method's parameters. For example, it could be useful if you have a `ForeignKey` in `REQUIRED_FIELDS` and want to allow creating an instance instead of entering the primary key of an existing instance.

`django.contrib.contenttypes`

`remove_stale_contenttypes`

`django-admin remove_stale_contenttypes`

This command is only available if Django's `contenttypes` app (`django.contrib.contenttypes`) is installed.

Deletes stale content types (from deleted models) in your database. Any objects that depend on the deleted content types will also be deleted. A list of deleted objects will be displayed before you confirm it's okay to proceed with the deletion.

--database DATABASE

Specifies the database to use. Defaults to `default`.

--include-stale-apps

Deletes stale content types including ones from previously installed apps that have been removed from `INSTALLED_APPS`. Defaults to `False`.

`django.contrib.gis`

`ogrinspect`

This command is only available if `GeoDjango` (`django.contrib.gis`) is installed.

Please refer to its *description* in the GeoDjango documentation.

`django.contrib.sessions`

`clearsessions`

`django-admin clearsessions`

Can be run as a cron job or directly to clean out expired sessions.

`django.contrib.sitemaps`

`ping_google`

This command is only available if the `Sitemaps framework` (`django.contrib.sitemaps`) is installed.

Please refer to its *description* in the Sitemaps documentation.

`django.contrib.staticfiles`

`collectstatic`

This command is only available if the [static files application](#) (`django.contrib.staticfiles`) is installed.

Please refer to its [description](#) in the [staticfiles](#) documentation.

`findstatic`

This command is only available if the [static files application](#) (`django.contrib.staticfiles`) is installed.

Please refer to its [description](#) in the [staticfiles](#) documentation.

6.8.4 Default options

Although some commands may allow their own custom options, every command allows for the following options by default:

`--pythonpath PYTHONPATH`

Adds the given filesystem path to the Python [import search path](#). If this isn't provided, `django-admin` will use the `PYTHONPATH` environment variable.

This option is unnecessary in `manage.py`, because it takes care of setting the Python path for you.

Example usage:

```
django-admin migrate --pythonpath='/home/djangoprojects/myproject'
```

`--settings SETTINGS`

Specifies the settings module to use. The settings module should be in Python package syntax, e.g. `mysite.settings`. If this isn't provided, `django-admin` will use the `DJANGO_SETTINGS_MODULE` environment variable.

This option is unnecessary in `manage.py`, because it uses `settings.py` from the current project by default.

Example usage:

```
django-admin migrate --settings=mysite.settings
```

`--traceback`

Displays a full stack trace when a [CommandError](#) is raised. By default, `django-admin` will show an error message when a `CommandError` occurs and a full stack trace for any other exception.

This option is ignored by [runserver](#).

Example usage:

```
django-admin migrate --traceback
```

--verbosity {0,1,2,3}, **-v** {0,1,2,3}

Specifies the amount of notification and debug information that a command should print to the console.

- 0 means no output.
- 1 means normal output (default).
- 2 means verbose output.
- 3 means very verbose output.

This option is ignored by *runserver*.

Example usage:

```
django-admin migrate --verbosity 2
```

--no-color

Disables colorized command output. Some commands format their output to be colorized. For example, errors will be printed to the console in red and SQL statements will be syntax highlighted.

Example usage:

```
django-admin runserver --no-color
```

--force-color

Forces colorization of the command output if it would otherwise be disabled as discussed in [Syntax coloring](#). For example, you may want to pipe colored output to another command.

--skip-checks

Skips running system checks prior to running the command. This option is only available if the *requires_system_checks* command attribute is not an empty list or tuple.

Example usage:

```
django-admin migrate --skip-checks
```

6.8.5 Extra niceties

Syntax coloring

DJANGO_COLORS

The `django-admin/``manage.py` commands will use pretty color-coded output if your terminal supports ANSI-colored output. It won't use the color codes if you're piping the command's output to another program unless the `--force-color` option is used.

Windows support

On Windows 10, the [Windows Terminal](#) application, [VS Code](#), and PowerShell (where virtual terminal processing is enabled) allow colored output, and are supported by default.

Under Windows, the legacy `cmd.exe` native console doesn't support ANSI escape sequences so by default there is no color output. In this case either of two third-party libraries are needed:

- Install [colorama](#), a Python package that translates ANSI color codes into Windows API calls. Django commands will detect its presence and will make use of its services to color output just like on Unix-based platforms. `colorama` can be installed via `pip`:

```
...\> py -m pip install colorama
```

- Install [ANSICON](#), a third-party tool that allows `cmd.exe` to process ANSI color codes. Django commands will detect its presence and will make use of its services to color output just like on Unix-based platforms.

Other modern terminal environments on Windows, that support terminal colors, but which are not automatically detected as supported by Django, may “fake” the installation of `ANSICON` by setting the appropriate environmental variable, `ANSICON="on"`.

Custom colors

The colors used for syntax highlighting can be customized. Django ships with three color palettes:

- **dark**, suited to terminals that show white text on a black background. This is the default palette.
- **light**, suited to terminals that show black text on a white background.
- **nocolor**, which disables syntax highlighting.

You select a palette by setting a `DJANGO_COLORS` environment variable to specify the palette you want to use. For example, to specify the **light** palette under a Unix or OS/X BASH shell, you would run the following at a command prompt:

```
export DJANGO_COLORS="light"
```

You can also customize the colors that are used. Django specifies a number of roles in which color is used:

- `error` - A major error.
- `notice` - A minor error.
- `success` - A success.
- `warning` - A warning.
- `sql_field` - The name of a model field in SQL.
- `sql_coltype` - The type of a model field in SQL.
- `sql_keyword` - An SQL keyword.
- `sql_table` - The name of a model in SQL.
- `http_info` - A 1XX HTTP Informational server response.
- `http_success` - A 2XX HTTP Success server response.
- `http_not_modified` - A 304 HTTP Not Modified server response.
- `http_redirect` - A 3XX HTTP Redirect server response other than 304.
- `http_not_found` - A 404 HTTP Not Found server response.
- `http_bad_request` - A 4XX HTTP Bad Request server response other than 404.
- `http_server_error` - A 5XX HTTP Server Error response.
- `migrate_heading` - A heading in a migrations management command.
- `migrate_label` - A migration name.

Each of these roles can be assigned a specific foreground and background color, from the following list:

- `black`
- `red`
- `green`
- `yellow`
- `blue`
- `magenta`
- `cyan`
- `white`

Each of these colors can then be modified by using the following display options:

- `bold`
- `underscore`
- `blink`
- `reverse`
- `conceal`

A color specification follows one of the following patterns:

- `role=fg`
- `role=fg/bg`
- `role=fg,option,option`
- `role=fg/bg,option,option`

where `role` is the name of a valid color role, `fg` is the foreground color, `bg` is the background color and each `option` is one of the color modifying options. Multiple color specifications are then separated by a semicolon. For example:

```
export DJANGO_COLORS="error=yellow/blue,blink;notice=magenta"
```

would specify that errors be displayed using blinking yellow on blue, and notices displayed using magenta. All other color roles would be left uncolored.

Colors can also be specified by extending a base palette. If you put a palette name in a color specification, all the colors implied by that palette will be loaded. So:

```
export DJANGO_COLORS="light;error=yellow/blue,blink;notice=magenta"
```

would specify the use of all the colors in the light color palette, except for the colors for errors and notices which would be overridden as specified.

Bash completion

If you use the Bash shell, consider installing the Django bash completion script, which lives in `extras/django_bash_completion` in the Django source distribution. It enables tab-completion of `django-admin` and `manage.py` commands, so you can, for instance...

- Type `django-admin`.
- Press `[TAB]` to see all available options.
- Type `sql`, then `[TAB]`, to see all available options whose names start with `sql`.

See [How to create custom django-admin commands](#) for how to add customized actions.

Black formatting

The Python files created by *startproject*, *startapp*, *optimizemigration*, *makemigrations*, and *squashmigrations* are formatted using the `black` command if it is present on your `PATH`.

If you have `black` globally installed, but do not wish it used for the current project, you can set the `PATH` explicitly:

```
PATH=path/to/venv/bin django-admin makemigrations
```

For commands using `stdout` you can pipe the output to `black` if needed:

```
django-admin inspectdb | black -
```

6.9 Running management commands from your code

```
django.core.management.call_command(name, *args, **options)
```

To call a management command from code use `call_command`.

name

the name of the command to call or a command object. Passing the name is preferred unless the object is required for testing.

***args**

a list of arguments accepted by the command. Arguments are passed to the argument parser, so you can use the same style as you would on the command line. For example, `call_command('flush', '--verbosity=0')`.

****options**

named options accepted on the command-line. Options are passed to the command without triggering the argument parser, which means you'll need to pass the correct type. For example, `call_command('flush', verbosity=0)` (zero must be an integer rather than a string).

Examples:

```
from django.core import management
from django.core.management.commands import loaddata

management.call_command("flush", verbosity=0, interactive=False)
management.call_command("loaddata", "test_data", verbosity=0)
management.call_command(loaddata.Command(), "test_data", verbosity=0)
```

Note that command options that take no arguments are passed as keywords with `True` or `False`, as you can see with the `interactive` option above.

Named arguments can be passed by using either one of the following syntaxes:

```
# Similar to the command line
management.call_command("dumpdata", "--natural-foreign")

# Named argument similar to the command line minus the initial dashes and
# with internal dashes replaced by underscores
management.call_command("dumpdata", natural_foreign=True)

# `use_natural_foreign_keys` is the option destination variable
management.call_command("dumpdata", use_natural_foreign_keys=True)
```

Some command options have different names when using `call_command()` instead of `django-admin` or `manage.py`. For example, `django-admin createsuperuser --no-input` translates to `call_command('createsuperuser', interactive=False)`. To find what keyword argument name to use for `call_command()`, check the command's source code for the `dest` argument passed to `parser.add_argument()`.

Command options which take multiple options are passed a list:

```
management.call_command("dumpdata", exclude=["contenttypes", "auth"])
```

The return value of the `call_command()` function is the same as the return value of the `handle()` method of the command.

6.9.1 Output redirection

Note that you can redirect standard output and error streams as all commands support the `stdout` and `stderr` options. For example, you could write:

```
with open("/path/to/command_output", "w") as f:
    management.call_command("dumpdata", stdout=f)
```

6.10 Django Exceptions

Django raises some of its own exceptions as well as standard Python exceptions.

6.10.1 Django Core Exceptions

Django core exception classes are defined in `django.core.exceptions`.

`AppRegistryNotReady`

exception `AppRegistryNotReady`

This exception is raised when attempting to use models before the [app loading process](#), which initializes the ORM, is complete.

`ObjectDoesNotExist`

exception `ObjectDoesNotExist`

The base class for `Model.DoesNotExist` exceptions. A `try/except` for `ObjectDoesNotExist` will catch `DoesNotExist` exceptions for all models.

See `get()`.

`EmptyResultSet`

exception `EmptyResultSet`

`EmptyResultSet` may be raised during query generation if a query won't return any results. Most Django projects won't encounter this exception, but it might be useful for implementing custom lookups and expressions.

`FullResultSet`

exception `FullResultSet`

`FullResultSet` may be raised during query generation if a query will match everything. Most Django projects won't encounter this exception, but it might be useful for implementing custom lookups and expressions.

`FieldDoesNotExist`

exception `FieldDoesNotExist`

The `FieldDoesNotExist` exception is raised by a model's `_meta.get_field()` method when the requested field does not exist on the model or on the model's parents.

MultipleObjectsReturned

exception MultipleObjectsReturned

The base class for *Model.MultipleObjectsReturned* exceptions. A `try/except` for `MultipleObjectsReturned` will catch *MultipleObjectsReturned* exceptions for all models.

See *get()*.

SuspiciousOperation

exception SuspiciousOperation

The *SuspiciousOperation* exception is raised when a user has performed an operation that should be considered suspicious from a security perspective, such as tampering with a session cookie. Subclasses of `SuspiciousOperation` include:

- `DisallowedHost`
- `DisallowedModelAdminLookup`
- `DisallowedModelAdminToField`
- `DisallowedRedirect`
- `InvalidSessionKey`
- `RequestDataTooBig`
- `SuspiciousFileOperation`
- `SuspiciousMultipartForm`
- `SuspiciousSession`
- `TooManyFieldsSent`
- `TooManyFilesSent`

If a `SuspiciousOperation` exception reaches the ASGI/WSGI handler level it is logged at the `Error` level and results in a *HttpResponseBadRequest*. See the [logging documentation](#) for more information.

`SuspiciousOperation` is raised when too many files are submitted.

PermissionDenied

exception PermissionDenied

The *PermissionDenied* exception is raised when a user does not have permission to perform the action requested.

`ViewDoesNotExist`

exception `ViewDoesNotExist`

The *`ViewDoesNotExist`* exception is raised by *`django.urls`* when a requested view does not exist.

`MiddlewareNotUsed`

exception `MiddlewareNotUsed`

The *`MiddlewareNotUsed`* exception is raised when a middleware is not used in the server configuration.

`ImproperlyConfigured`

exception `ImproperlyConfigured`

The *`ImproperlyConfigured`* exception is raised when Django is somehow improperly configured –for example, if a value in `settings.py` is incorrect or unparseable.

`FieldError`

exception `FieldError`

The *`FieldError`* exception is raised when there is a problem with a model field. This can happen for several reasons:

- A field in a model clashes with a field of the same name from an abstract base class
- An infinite loop is caused by ordering
- A keyword cannot be parsed from the filter parameters
- A field cannot be determined from a keyword in the query parameters
- A join is not permitted on the specified field
- A field name is invalid
- A query contains invalid `order_by` arguments

`ValidationError`

exception `ValidationError`

The *`ValidationError`* exception is raised when data fails form or model field validation. For more information about validation, see [Form and Field Validation](#), [Model Field Validation](#) and the [Validator Reference](#).

NON_FIELD_ERRORS

NON_FIELD_ERRORS

`ValidationErrors` that don't belong to a particular field in a form or model are classified as `NON_FIELD_ERRORS`. This constant is used as a key in dictionaries that otherwise map fields to their respective list of errors.

BadRequest

exception `BadRequest`

The `BadRequest` exception is raised when the request cannot be processed due to a client error. If a `BadRequest` exception reaches the ASGI/WSGI handler level it results in a `HttpResponseBadRequest`.

RequestAborted

exception `RequestAborted`

The `RequestAborted` exception is raised when an HTTP body being read in by the handler is cut off midstream and the client connection closes, or when the client does not send data and hits a timeout where the server closes the connection.

It is internal to the HTTP handler modules and you are unlikely to see it elsewhere. If you are modifying HTTP handling code, you should raise this when you encounter an aborted request to make sure the socket is closed cleanly.

SynchronousOnlyOperation

exception `SynchronousOnlyOperation`

The `SynchronousOnlyOperation` exception is raised when code that is only allowed in synchronous Python code is called from an asynchronous context (a thread with a running asynchronous event loop). These parts of Django are generally heavily reliant on thread-safety to function and don't work correctly under coroutines sharing the same thread.

If you are trying to call code that is synchronous-only from an asynchronous thread, then create a synchronous thread and call it in that. You can accomplish this with `asgiref.sync.sync_to_async()`.

6.10.2 URL Resolver exceptions

URL Resolver exceptions are defined in `django.urls`.

`Resolver404`

exception `Resolver404`

The `Resolver404` exception is raised by `resolve()` if the path passed to `resolve()` doesn't map to a view. It's a subclass of `django.http.Http404`.

`NoReverseMatch`

exception `NoReverseMatch`

The `NoReverseMatch` exception is raised by `django.urls` when a matching URL in your URLconf cannot be identified based on the parameters supplied.

6.10.3 Database Exceptions

Database exceptions may be imported from `django.db`.

Django wraps the standard database exceptions so that your Django code has a guaranteed common implementation of these classes.

exception `Error`

exception `InterfaceError`

exception `DatabaseError`

exception `DataError`

exception `OperationalError`

exception `IntegrityError`

exception `InternalError`

exception `ProgrammingError`

exception `NotSupportedError`

The Django wrappers for database exceptions behave exactly the same as the underlying database exceptions. See [PEP 249](#), the Python Database API Specification v2.0, for further information.

As per [PEP 3134](#), a `__cause__` attribute is set with the original (underlying) database exception, allowing access to any additional information provided.

`exception models.ProtectedError`

Raised to prevent deletion of referenced objects when using `django.db.models.PROTECT`. `models.ProtectedError` is a subclass of `IntegrityError`.

`exception models.RestrictedError`

Raised to prevent deletion of referenced objects when using `django.db.models.RESTRICT`. `models.RestrictedError` is a subclass of `IntegrityError`.

6.10.4 HTTP Exceptions

HTTP exceptions may be imported from `django.http`.

`UnreadablePostError`

`exception UnreadablePostError`

`UnreadablePostError` is raised when a user cancels an upload.

6.10.5 Sessions Exceptions

Sessions exceptions are defined in `django.contrib.sessions.exceptions`.

`SessionInterrupted`

`exception SessionInterrupted`

`SessionInterrupted` is raised when a session is destroyed in a concurrent request. It's a subclass of `BadRequest`.

6.10.6 Transaction Exceptions

Transaction exceptions are defined in `django.db.transaction`.

`TransactionManagementError`

`exception TransactionManagementError`

`TransactionManagementError` is raised for any and all problems related to database transactions.

6.10.7 Testing Framework Exceptions

Exceptions provided by the `django.test` package.

`RedirectCycleError`

exception `client.RedirectCycleError`

RedirectCycleError is raised when the test client detects a loop or an overly long chain of redirects.

6.10.8 Python Exceptions

Django raises built-in Python exceptions when appropriate as well. See the Python documentation for further information on the [Built-in Exceptions](#).

6.11 File handling

6.11.1 The File object

The *django.core.files* module and its submodules contain built-in classes for basic file handling in Django.

The File class

class `File(file_object, name=None)`

The *File* class is a thin wrapper around a Python [file object](#) with some Django-specific additions. Internally, Django uses this class when it needs to represent a file.

File objects have the following attributes and methods:

name

The name of the file including the relative path from *MEDIA_ROOT*.

size

The size of the file in bytes.

file

The underlying [file object](#) that this class wraps.

Be careful with this attribute in subclasses.

Some subclasses of *File*, including *ContentFile* and *FieldFile*, may replace this attribute with an object other than a Python [file object](#). In these cases, this attribute may itself be a *File* subclass

(and not necessarily the same subclass). Whenever possible, use the attributes and methods of the subclass itself rather than the those of the subclass's `file` attribute.

mode

The read/write mode for the file.

open(mode=None)

Open or reopen the file (which also does `File.seek(0)`). The `mode` argument allows the same values as Python's built-in `open()`.

When reopening a file, `mode` will override whatever mode the file was originally opened with; `None` means to reopen with the original mode.

It can be used as a context manager, e.g. with `file.open()` as `f`:

__iter__()

Iterate over the file yielding one line at a time.

chunks(chunk_size=None)

Iterate over the file yielding “chunks” of a given size. `chunk_size` defaults to 64 KB.

This is especially useful with very large files since it allows them to be streamed off disk and avoids storing the whole file in memory.

multiple_chunks(chunk_size=None)

Returns `True` if the file is large enough to require multiple chunks to access all of its content give some `chunk_size`.

close()

Close the file.

In addition to the listed methods, *File* exposes the following attributes and methods of its `file` object: `encoding`, `fileno`, `flush`, `isatty`, `newlines`, `read`, `readinto`, `readline`, `readlines`, `seek`, `tell`, `truncate`, `write`, `writelines`, `readable()`, `writable()`, and `seekable()`.

The `ContentFile` class

class ContentFile(content, name=None)

The `ContentFile` class inherits from *File*, but unlike *File* it operates on string content (bytes also supported), rather than an actual file. For example:

```
from django.core.files.base import ContentFile

f1 = ContentFile("esta frase está en español")
f2 = ContentFile(b"these are bytes")
```

The `ImageFile` class

`class ImageFile(file_object, name=None)`

Django provides a built-in class specifically for images. `django.core.files.images.ImageField` inherits all the attributes and methods of `File`, and additionally provides the following:

width

Width of the image in pixels.

height

Height of the image in pixels.

Additional methods on files attached to objects

Any `File` that is associated with an object (as with `Car.photo`, below) will also have a couple of extra methods:

`File.save(name, content, save=True)`

Saves a new file with the file name and contents provided. This will not replace the existing file, but will create a new file and update the object to point to it. If `save` is `True`, the model's `save()` method will be called once the file is saved. That is, these two lines:

```
>>> car.photo.save("myphoto.jpg", content, save=False)
>>> car.save()
```

are equivalent to:

```
>>> car.photo.save("myphoto.jpg", content, save=True)
```

Note that the `content` argument must be an instance of either `File` or of a subclass of `File`, such as `ContentFile`.

`File.delete(save=True)`

Removes the file from the model instance and deletes the underlying file. If `save` is `True`, the model's `save()` method will be called once the file is deleted.

6.11.2 File storage API

Getting the default storage class

Django provides convenient ways to access the default storage class:

storages

Storage instances as defined by `STORAGES`.

class DefaultStorage

DefaultStorage provides lazy access to the default storage system as defined by default key in *STORAGES*. *DefaultStorage* uses *storages* internally.

default_storage

default_storage is an instance of the *DefaultStorage*.

get_storage_class(import_path=None)

Returns a class or module which implements the storage API.

When called without the `import_path` parameter `get_storage_class` will return the default storage system as defined by default key in *STORAGES*. If `import_path` is provided, `get_storage_class` will attempt to import the class or module from the given path and will return it if successful. An exception will be raised if the import is unsuccessful.

Deprecated since version 4.2: The `get_storage_class()` function is deprecated. Use *storages* instead

The FileSystemStorage class

```
class FileSystemStorage(location=None, base_url=None, file_permissions_mode=None,
                        directory_permissions_mode=None)
```

The *FileSystemStorage* class implements basic file storage on a local filesystem. It inherits from *Storage* and provides implementations for all the public methods thereof.

location

Absolute path to the directory that will hold the files. Defaults to the value of your *MEDIA_ROOT* setting.

base_url

URL that serves the files stored at this location. Defaults to the value of your *MEDIA_URL* setting.

file_permissions_mode

The file system permissions that the file will receive when it is saved. Defaults to *FILE_UPLOAD_PERMISSIONS*.

directory_permissions_mode

The file system permissions that the directory will receive when it is saved. Defaults to *FILE_UPLOAD_DIRECTORY_PERMISSIONS*.

Note: The `FileSystemStorage.delete()` method will not raise an exception if the given file name does not exist.

get_created_time(name)

Returns a *datetime* of the system's ctime, i.e. `os.path.getctime()`. On some systems (like Unix),

this is the time of the last metadata change, and on others (like Windows), it's the creation time of the file.

The `InMemoryStorage` class

```
class InMemoryStorage(location=None, base_url=None, file_permissions_mode=None,
                      directory_permissions_mode=None)
```

The `InMemoryStorage` class implements a memory-based file storage. It has no persistence, but can be useful for speeding up tests by avoiding disk access.

`location`

Absolute path to the directory name assigned to files. Defaults to the value of your `MEDIA_ROOT` setting.

`base_url`

URL that serves the files stored at this location. Defaults to the value of your `MEDIA_URL` setting.

`file_permissions_mode`

The file system permissions assigned to files, provided for compatibility with `FileSystemStorage`. Defaults to `FILE_UPLOAD_PERMISSIONS`.

`directory_permissions_mode`

The file system permissions assigned to directories, provided for compatibility with `FileSystemStorage`. Defaults to `FILE_UPLOAD_DIRECTORY_PERMISSIONS`.

The `Storage` class

```
class Storage
```

The `Storage` class provides a standardized API for storing files, along with a set of default behaviors that all other storage systems can inherit or override as necessary.

Note: When methods return naive `datetime` objects, the effective timezone used will be the current value of `os.environ['TZ']`; note that this is usually set from Django's `TIME_ZONE`.

`delete(name)`

Deletes the file referenced by `name`. If deletion is not supported on the target storage system this will raise `NotImplementedError` instead.

`exists(name)`

Returns `True` if a file referenced by the given name already exists in the storage system, or `False` if the name is available for a new file.

get_accessed_time(name)

Returns a `datetime` of the last accessed time of the file. For storage systems unable to return the last accessed time this will raise `NotImplementedError`.

If `USE_TZ` is `True`, returns an aware `datetime`, otherwise returns a naive `datetime` in the local timezone.

get_alternative_name(file_root, file_ext)

Returns an alternative filename based on the `file_root` and `file_ext` parameters, an underscore plus a random 7 character alphanumeric string is appended to the filename before the extension.

get_available_name(name, max_length=None)

Returns a filename based on the `name` parameter that's free and available for new content to be written to on the target storage system.

The length of the filename will not exceed `max_length`, if provided. If a free unique filename cannot be found, a `SuspiciousFileOperation` exception will be raised.

If a file with `name` already exists, `get_alternative_name()` is called to obtain an alternative name.

get_created_time(name)

Returns a `datetime` of the creation time of the file. For storage systems unable to return the creation time this will raise `NotImplementedError`.

If `USE_TZ` is `True`, returns an aware `datetime`, otherwise returns a naive `datetime` in the local timezone.

get_modified_time(name)

Returns a `datetime` of the last modified time of the file. For storage systems unable to return the last modified time this will raise `NotImplementedError`.

If `USE_TZ` is `True`, returns an aware `datetime`, otherwise returns a naive `datetime` in the local timezone.

get_valid_name(name)

Returns a filename based on the `name` parameter that's suitable for use on the target storage system.

generate_filename(filename)

Validates the `filename` by calling `get_valid_name()` and returns a filename to be passed to the `save()` method.

The `filename` argument may include a path as returned by `FileField.upload_to`. In that case, the path won't be passed to `get_valid_name()` but will be prepended back to the resulting name.

The default implementation uses `os.path` operations. Override this method if that's not appropriate for your storage.

listdir(path)

Lists the contents of the specified path, returning a 2-tuple of lists; the first item being directories, the second item being files. For storage systems that aren't able to provide such a listing, this will raise a `NotImplementedError` instead.

open(name, mode='rb')

Opens the file given by `name`. Note that although the returned file is guaranteed to be a `File` object, it might actually be some subclass. In the case of remote file storage this means that reading/writing could be quite slow, so be warned.

path(name)

The local filesystem path where the file can be opened using Python's standard `open()`. For storage systems that aren't accessible from the local filesystem, this will raise `NotImplementedError` instead.

save(name, content, max_length=None)

Saves a new file using the storage system, preferably with the name specified. If there already exists a file with this name `name`, the storage system may modify the filename as necessary to get a unique name. The actual name of the stored file will be returned.

The `max_length` argument is passed along to `get_available_name()`.

The `content` argument must be an instance of `django.core.files.File` or a file-like object that can be wrapped in `File`.

size(name)

Returns the total size, in bytes, of the file referenced by `name`. For storage systems that aren't able to return the file size this will raise `NotImplementedError` instead.

url(name)

Returns the URL where the contents of the file referenced by `name` can be accessed. For storage systems that don't support access by URL this will raise `NotImplementedError` instead.

6.11.3 Uploaded Files and Upload Handlers

Uploaded files

class `UploadedFile`

During file uploads, the actual file data is stored in `request.FILES`. Each entry in this dictionary is an `UploadedFile` object (or a subclass) –a wrapper around an uploaded file. You'll usually use one of these methods to access the uploaded content:

`UploadedFile.read()`

Read the entire uploaded data from the file. Be careful with this method: if the uploaded file is huge it

can overwhelm your system if you try to read it into memory. You’ ll probably want to use `chunks()` instead; see below.

`UploadedFile.multiple_chunks(chunk_size=None)`

Returns `True` if the uploaded file is big enough to require reading in multiple chunks. By default this will be any file larger than 2.5 megabytes, but that’ s configurable; see below.

`UploadedFile.chunks(chunk_size=None)`

A generator returning chunks of the file. If `multiple_chunks()` is `True`, you should use this method in a loop instead of `read()`.

In practice, it’ s often easiest to use `chunks()` all the time. Looping over `chunks()` instead of using `read()` ensures that large files don’ t overwhelm your system’ s memory.

Here are some useful attributes of `UploadedFile`:

`UploadedFile.name`

The name of the uploaded file (e.g. `my_file.txt`).

`UploadedFile.size`

The size, in bytes, of the uploaded file.

`UploadedFile.content_type`

The content-type header uploaded with the file (e.g. `text/plain` or `application/pdf`). Like any data supplied by the user, you shouldn’ t trust that the uploaded file is actually this type. You’ ll still need to validate that the file contains the content that the content-type header claims – “trust but verify.”

`UploadedFile.content_type_extra`

A dictionary containing extra parameters passed to the `content-type` header. This is typically provided by services, such as Google App Engine, that intercept and handle file uploads on your behalf. As a result your handler may not receive the uploaded file content, but instead a URL or other pointer to the file (see [RFC 2388](#)).

`UploadedFile.charset`

For `text/*` content-types, the character set (i.e. `utf8`) supplied by the browser. Again, “trust but verify” is the best policy here.

Note: Like regular Python files, you can read the file line-by-line by iterating over the uploaded file:

```
for line in uploadedfile:
    do_something_with(line)
```

Lines are split using [universal newlines](#). The following are recognized as ending a line: the Unix end-of-line convention `'\n'`, the Windows convention `'\r\n'`, and the old Macintosh convention `'\r'`.

Subclasses of `UploadedFile` include:

```
class TemporaryUploadedFile
```

A file uploaded to a temporary location (i.e. stream-to-disk). This class is used by the *TemporaryFileUploadHandler*. In addition to the methods from *UploadedFile*, it has one additional method:

```
TemporaryUploadedFile.temporary_file_path()
```

Returns the full path to the temporary uploaded file.

```
class InMemoryUploadedFile
```

A file uploaded into memory (i.e. stream-to-memory). This class is used by the *MemoryFileUploadHandler*.

Built-in upload handlers

Together the *MemoryFileUploadHandler* and *TemporaryFileUploadHandler* provide Django's default file upload behavior of reading small files into memory and large ones onto disk. They are located in `django.core.files.uploadhandler`.

```
class MemoryFileUploadHandler
```

File upload handler to stream uploads into memory (used for small files).

```
class TemporaryFileUploadHandler
```

Upload handler that streams data into a temporary file using *TemporaryUploadedFile*.

Writing custom upload handlers

```
class FileUploadHandler
```

All file upload handlers should be subclasses of `django.core.files.uploadhandler.FileUploadHandler`. You can define upload handlers wherever you wish.

Required methods

Custom file upload handlers must define the following methods:

```
FileUploadHandler.receive_data_chunk(raw_data, start)
```

Receives a “chunk” of data from the file upload.

`raw_data` is a bytestring containing the uploaded data.

`start` is the position in the file where this `raw_data` chunk begins.

The data you return will get fed into the subsequent upload handlers' `receive_data_chunk` methods. In this way, one handler can be a “filter” for other handlers.

Return `None` from `receive_data_chunk` to short-circuit remaining upload handlers from getting this chunk. This is useful if you’re storing the uploaded data yourself and don’t want future handlers to store a copy of the data.

If you raise a `StopUpload` or a `SkipFile` exception, the upload will abort or the file will be completely skipped.

`FileUploadHandler.file_complete(file_size)`

Called when a file has finished uploading.

The handler should return an `UploadedFile` object that will be stored in `request.FILES`. Handlers may also return `None` to indicate that the `UploadedFile` object should come from subsequent upload handlers.

Optional methods

Custom upload handlers may also define any of the following optional methods or attributes:

`FileUploadHandler.chunk_size`

Size, in bytes, of the “chunks” Django should store into memory and feed into the handler. That is, this attribute controls the size of chunks fed into `FileUploadHandler.receive_data_chunk`.

For maximum performance the chunk sizes should be divisible by 4 and should not exceed 2 GB (2^{31} bytes) in size. When there are multiple chunk sizes provided by multiple handlers, Django will use the smallest chunk size defined by any handler.

The default is 64×2^{10} bytes, or 64 KB.

`FileUploadHandler.new_file(field_name, file_name, content_type, content_length, charset, content_type_extra)`

Callback signaling that a new file upload is starting. This is called before any data has been fed to any upload handlers.

`field_name` is a string name of the file `<input>` field.

`file_name` is the filename provided by the browser.

`content_type` is the MIME type provided by the browser –E.g. `'image/jpeg'`.

`content_length` is the length of the image given by the browser. Sometimes this won’t be provided and will be `None`.

`charset` is the character set (i.e. `utf8`) given by the browser. Like `content_length`, this sometimes won’t be provided.

`content_type_extra` is extra information about the file from the `content-type` header. See [`UploadedFile.content\_type\_extra`](#).

This method may raise a `StopFutureHandlers` exception to prevent future handlers from handling this file.

`FileUploadHandler.upload_complete()`

Callback signaling that the entire upload (all files) has completed.

`FileUploadHandler.upload_interrupted()`

Callback signaling that the upload was interrupted, e.g. when the user closed their browser during file upload.

`FileUploadHandler.handle_raw_input(input_data, META, content_length, boundary, encoding)`

Allows the handler to completely override the parsing of the raw HTTP input.

`input_data` is a file-like object that supports `read()`-ing.

`META` is the same object as `request.META`.

`content_length` is the length of the data in `input_data`. Don't read more than `content_length` bytes from `input_data`.

`boundary` is the MIME boundary for this request.

`encoding` is the encoding of the request.

Return `None` if you want upload handling to continue, or a tuple of `(POST, FILES)` if you want to return the new data structures suitable for the request directly.

6.12 Forms

Detailed form API reference. For introductory material, see the [Working with forms](#) topic guide.

6.12.1 The Forms API

About this document

This document covers the gritty details of Django's forms API. You should read the [introduction to working with forms](#) first.

Bound and unbound forms

A *Form* instance is either bound to a set of data, or unbound.

- If it's bound to a set of data, it's capable of validating that data and rendering the form as HTML with the data displayed in the HTML.
- If it's unbound, it cannot do validation (because there's no data to validate!), but it can still render the blank form as HTML.

```
class Form
```

To create an unbound *Form* instance, instantiate the class:

```
>>> f = ContactForm()
```

To bind data to a form, pass the data as a dictionary as the first parameter to your *Form* class constructor:

```
>>> data = {  
...     "subject": "hello",  
...     "message": "Hi there",  
...     "sender": "foo@example.com",  
...     "cc_myself": True,  
... }  
>>> f = ContactForm(data)
```

In this dictionary, the keys are the field names, which correspond to the attributes in your *Form* class. The values are the data you're trying to validate. These will usually be strings, but there's no requirement that they be strings; the type of data you pass depends on the *Field*, as we'll see in a moment.

Form.is_bound

If you need to distinguish between bound and unbound form instances at runtime, check the value of the form's *is_bound* attribute:

```
>>> f = ContactForm()  
>>> f.is_bound  
False  
>>> f = ContactForm({"subject": "hello"})  
>>> f.is_bound  
True
```

Note that passing an empty dictionary creates a bound form with empty data:

```
>>> f = ContactForm({})  
>>> f.is_bound  
True
```

If you have a bound *Form* instance and want to change the data somehow, or if you want to bind an unbound *Form* instance to some data, create another *Form* instance. There is no way to change data in a *Form* instance. Once a *Form* instance has been created, you should consider its data immutable, whether it has data or not.

Using forms to validate data

`Form.clean()`

Implement a `clean()` method on your *Form* when you must add custom validation for fields that are inter-dependent. See [Cleaning and validating fields that depend on each other](#) for example usage.

`Form.is_valid()`

The primary task of a *Form* object is to validate data. With a bound *Form* instance, call the `is_valid()` method to run validation and return a boolean designating whether the data was valid:

```
>>> data = {
...     "subject": "hello",
...     "message": "Hi there",
...     "sender": "foo@example.com",
...     "cc_myself": True,
... }
>>> f = ContactForm(data)
>>> f.is_valid()
True
```

Let's try with some invalid data. In this case, `subject` is blank (an error, because all fields are required by default) and `sender` is not a valid email address:

```
>>> data = {
...     "subject": "",
...     "message": "Hi there",
...     "sender": "invalid email address",
...     "cc_myself": True,
... }
>>> f = ContactForm(data)
>>> f.is_valid()
False
```

`Form.errors`

Access the `errors` attribute to get a dictionary of error messages:

```
>>> f.errors
{'sender': ['Enter a valid email address.'], 'subject': ['This field is required.']}
```

In this dictionary, the keys are the field names, and the values are lists of strings representing the error messages. The error messages are stored in lists because a field can have multiple error messages.

You can access `errors` without having to call `is_valid()` first. The form's data will be validated the first time either you call `is_valid()` or access `errors`.

The validation routines will only get called once, regardless of how many times you access `errors` or call `is_valid()`. This means that if validation has side effects, those side effects will only be triggered once.

`Form.errors.as_data()`

Returns a dict that maps fields to their original `ValidationError` instances.

```
>>> f.errors.as_data()
{'sender': [ValidationError(['Enter a valid email address.'])],
'subject': [ValidationError(['This field is required.'])]}
```

Use this method anytime you need to identify an error by its code. This enables things like rewriting the error's message or writing custom logic in a view when a given error is present. It can also be used to serialize the errors in a custom format (e.g. XML); for instance, `as_json()` relies on `as_data()`.

The need for the `as_data()` method is due to backwards compatibility. Previously `ValidationError` instances were lost as soon as their rendered error messages were added to the `Form.errors` dictionary. Ideally `Form.errors` would have stored `ValidationError` instances and methods with an `as_` prefix could render them, but it had to be done the other way around in order not to break code that expects rendered error messages in `Form.errors`.

`Form.errors.as_json(escape_html=False)`

Returns the errors serialized as JSON.

```
>>> f.errors.as_json()
{"sender": [{"message": "Enter a valid email address.", "code": "invalid"}],
"subject": [{"message": "This field is required.", "code": "required"}]}
```

By default, `as_json()` does not escape its output. If you are using it for something like AJAX requests to a form view where the client interprets the response and inserts errors into the page, you'll want to be sure to escape the results on the client-side to avoid the possibility of a cross-site scripting attack. You can do this in JavaScript with `element.textContent = errorText` or with jQuery's `$(el).text(errorText)` (rather than its `.html()` function).

If for some reason you don't want to use client-side escaping, you can also set `escape_html=True` and error messages will be escaped so you can use them directly in HTML.

`Form.errors.get_json_data(escape_html=False)`

Returns the errors as a dictionary suitable for serializing to JSON. `Form.errors.as_json()` returns serialized JSON, while this returns the error data before it's serialized.

The `escape_html` parameter behaves as described in [`Form.errors.as\_json\(\)`](#).

`Form.add_error(field, error)`

This method allows adding errors to specific fields from within the `Form.clean()` method, or from outside the form altogether; for instance from a view.

The `field` argument is the name of the field to which the errors should be added. If its value is `None` the error will be treated as a non-field error as returned by [`Form.non\_field\_errors\(\)`](#).

The `error` argument can be a string, or preferably an instance of `ValidationError`. See [Raising Validation-Error](#) for best practices when defining form errors.

Note that `Form.add_error()` automatically removes the relevant field from `cleaned_data`.

`Form.has_error(field, code=None)`

This method returns a boolean designating whether a field has an error with a specific error `code`. If `code` is `None`, it will return `True` if the field contains any errors at all.

To check for non-field errors use `NON_FIELD_ERRORS` as the `field` parameter.

`Form.non_field_errors()`

This method returns the list of errors from [`Form.errors`](#) that aren't associated with a particular field. This includes `ValidationErrors` that are raised in [`Form.clean\(\)`](#) and errors added using [`Form.add\_error\(None, "..."\)`](#).

Behavior of unbound forms

It's meaningless to validate a form with no data, but, for the record, here's what happens with unbound forms:

```
>>> f = ContactForm()
>>> f.is_valid()
False
>>> f.errors
{}
```

Initial form values

`Form.initial`

Use *initial* to declare the initial value of form fields at runtime. For example, you might want to fill in a `username` field with the username of the current session.

To accomplish this, use the *initial* argument to a *Form*. This argument, if given, should be a dictionary mapping field names to initial values. Only include the fields for which you're specifying an initial value; it's not necessary to include every field in your form. For example:

```
>>> f = ContactForm(initial={"subject": "Hi there!"})
```

These values are only displayed for unbound forms, and they're not used as fallback values if a particular value isn't provided.

If a *Field* defines *initial* and you include *initial* when instantiating the Form, then the latter *initial* will have precedence. In this example, *initial* is provided both at the field level and at the form instance level, and the latter gets precedence:

```
>>> from django import forms
>>> class CommentForm(forms.Form):
...     name = forms.CharField(initial="class")
...     url = forms.URLField()
...     comment = forms.CharField()
...
>>> f = CommentForm(initial={"name": "instance"}, auto_id=False)
>>> print(f)
<tr><th>Name:</th><td><input type="text" name="name" value="instance" required></td></tr>
<tr><th>Url:</th><td><input type="url" name="url" required></td></tr>
<tr><th>Comment:</th><td><input type="text" name="comment" required></td></tr>
```

`Form.get_initial_for_field(field, field_name)`

Returns the initial data for a form field. It retrieves the data from *Form.initial* if present, otherwise trying *Field.initial*. Callable values are evaluated.

It is recommended to use *BoundField.initial* over *get_initial_for_field()* because *BoundField.initial* has a simpler interface. Also, unlike *get_initial_for_field()*, *BoundField.initial* caches its values. This is useful especially when dealing with callables whose return values can change (e.g. `datetime.now` or `uuid.uuid4`):

```
>>> import uuid
>>> class UUIDCommentForm(CommentForm):
...     identifier = forms.UUIDField(initial=uuid.uuid4)
...
>>> f = UUIDCommentForm()
>>> f.get_initial_for_field(f.fields["identifier"], "identifier")
UUID('972ca9e4-7bfe-4f5b-af7d-07b3aa306334')
>>> f.get_initial_for_field(f.fields["identifier"], "identifier")
UUID('1b411fab-844e-4dec-bd4f-e9b0495f04d0')
>>> # Using BoundField.initial, for comparison
>>> f["identifier"].initial
```

(continues on next page)

(continued from previous page)

```

UUID('28a09c59-5f00-4ed9-9179-a3b074fa9c30')
>>> f["identifier"].initial
UUID('28a09c59-5f00-4ed9-9179-a3b074fa9c30')

```

Checking which form data has changed

`Form.has_changed()`

Use the `has_changed()` method on your `Form` when you need to check if the form data has been changed from the initial data.

```

>>> data = {'subject': 'hello',
...         'message': 'Hi there',
...         'sender': 'foo@example.com',
...         'cc_myself': True}
>>> f = ContactForm(data, initial=data)
>>> f.has_changed()
False

```

When the form is submitted, we reconstruct it and provide the original data so that the comparison can be done:

```

>>> f = ContactForm(request.POST, initial=data)
>>> f.has_changed()

```

`has_changed()` will be `True` if the data from `request.POST` differs from what was provided in *initial* or `False` otherwise. The result is computed by calling *Field.has_changed()* for each field in the form.

`Form.changed_data`

The `changed_data` attribute returns a list of the names of the fields whose values in the form's bound data (usually `request.POST`) differ from what was provided in *initial*. It returns an empty list if no data differs.

```

>>> f = ContactForm(request.POST, initial=data)
>>> if f.has_changed():
...     print("The following fields changed: %s" % ", ".join(f.changed_data))
>>> f.changed_data
['subject', 'message']

```

Accessing the fields from the form

Form.fields

You can access the fields of *Form* instance from its `fields` attribute:

```
>>> for row in f.fields.values():
...     print(row)
...
<django.forms.fields.CharField object at 0x7ffaac632510>
<django.forms.fields.URLField object at 0x7ffaac632f90>
<django.forms.fields.CharField object at 0x7ffaac3aa050>
>>> f.fields["name"]
<django.forms.fields.CharField object at 0x7ffaac6324d0>
```

You can alter the field and *BoundField* of *Form* instance to change the way it is presented in the form:

```
>>> f.as_div().split("</div>")[0]
'<div><label for="id_subject">Subject:</label><input type="text" name="subject" maxlength="100"
↳required id="id_subject">'
>>> f["subject"].label = "Topic"
>>> f.as_div().split("</div>")[0]
'<div><label for="id_subject">Topic:</label><input type="text" name="subject" maxlength="100"
↳required id="id_subject">'
```

Beware not to alter the `base_fields` attribute because this modification will influence all subsequent *ContactForm* instances within the same Python process:

```
>>> f.base_fields["subject"].label_suffix = "?"
>>> another_f = CommentForm(auto_id=False)
>>> f.as_div().split("</div>")[0]
'<div><label for="id_subject">Subject?</label><input type="text" name="subject" maxlength="100"
↳required id="id_subject">'
```

Accessing “clean” data

Form.cleaned_data

Each field in a *Form* class is responsible not only for validating data, but also for “cleaning” it –normalizing it to a consistent format. This is a nice feature, because it allows data for a particular field to be input in a variety of ways, always resulting in consistent output.

For example, *DateField* normalizes input into a Python `datetime.date` object. Regardless of whether you pass it a string in the format `'1994-07-15'`, a `datetime.date` object, or a number of other formats, *DateField* will always normalize it to a `datetime.date` object as long as it's valid.

Once you’ve created a *Form* instance with a set of data and validated it, you can access the clean data via its `cleaned_data` attribute:

```
>>> data = {
...     "subject": "hello",
...     "message": "Hi there",
...     "sender": "foo@example.com",
...     "cc_myself": True,
... }
>>> f = ContactForm(data)
>>> f.is_valid()
True
>>> f.cleaned_data
{'cc_myself': True, 'message': 'Hi there', 'sender': 'foo@example.com', 'subject': 'hello'}
```

Note that any text-based field—such as `CharField` or `EmailField`—always cleans the input into a string. We’ll cover the encoding implications later in this document.

If your data does not validate, the `cleaned_data` dictionary contains only the valid fields:

```
>>> data = {
...     "subject": "",
...     "message": "Hi there",
...     "sender": "invalid email address",
...     "cc_myself": True,
... }
>>> f = ContactForm(data)
>>> f.is_valid()
False
>>> f.cleaned_data
{'cc_myself': True, 'message': 'Hi there'}
```

`cleaned_data` will always only contain a key for fields defined in the Form, even if you pass extra data when you define the Form. In this example, we pass a bunch of extra fields to the `ContactForm` constructor, but `cleaned_data` contains only the form’s fields:

```
>>> data = {
...     "subject": "hello",
...     "message": "Hi there",
...     "sender": "foo@example.com",
...     "cc_myself": True,
...     "extra_field_1": "foo",
...     "extra_field_2": "bar",
...     "extra_field_3": "baz",
... }
```

(continues on next page)

(continued from previous page)

```
>>> f = ContactForm(data)
>>> f.is_valid()
True
>>> f.cleaned_data # Doesn't contain extra_field_1, etc.
{'cc_myself': True, 'message': 'Hi there', 'sender': 'foo@example.com', 'subject': 'hello'}
```

When the Form is valid, `cleaned_data` will include a key and value for all its fields, even if the data didn't include a value for some optional fields. In this example, the data dictionary doesn't include a value for the `nick_name` field, but `cleaned_data` includes it, with an empty value:

```
>>> from django import forms
>>> class OptionalPersonForm(forms.Form):
...     first_name = forms.CharField()
...     last_name = forms.CharField()
...     nick_name = forms.CharField(required=False)
...
>>> data = {"first_name": "John", "last_name": "Lennon"}
>>> f = OptionalPersonForm(data)
>>> f.is_valid()
True
>>> f.cleaned_data
{'nick_name': '', 'first_name': 'John', 'last_name': 'Lennon'}
```

In this above example, the `cleaned_data` value for `nick_name` is set to an empty string, because `nick_name` is `CharField`, and `CharFields` treat empty values as an empty string. Each field type knows what its “blank” value is –e.g., for `DateField`, it's `None` instead of the empty string. For full details on each field's behavior in this case, see the “Empty value” note for each field in the “Built-in Field classes” section below.

You can write code to perform validation for particular form fields (based on their name) or for the form as a whole (considering combinations of various fields). More information about this is in [Form and field validation](#).

Outputting forms as HTML

The second task of a Form object is to render itself as HTML. To do so, print it:

```
>>> f = ContactForm()
>>> print(f)
<tr><th><label for="id_subject">Subject:</label></th><td><input id="id_subject" type="text" name=
↪ "subject" maxlength="100" required></td></tr>
<tr><th><label for="id_message">Message:</label></th><td><input type="text" name="message" id="id_
↪ message" required></td></tr>
<tr><th><label for="id_sender">Sender:</label></th><td><input type="email" name="sender" id="id_
```

(continues on next page)

(continued from previous page)

```

↪sender" required></td></tr>
<tr><th><label for="id_cc_myself">Cc myself:</label></th><td><input type="checkbox" name="cc_myself
↪" id="id_cc_myself"></td></tr>

```

If the form is bound to data, the HTML output will include that data appropriately. For example, if a field is represented by an `<input type="text">`, the data will be in the `value` attribute. If a field is represented by an `<input type="checkbox">`, then that HTML will include `checked` if appropriate:

```

>>> data = {
...     "subject": "hello",
...     "message": "Hi there",
...     "sender": "foo@example.com",
...     "cc_myself": True,
... }
>>> f = ContactForm(data)
>>> print(f)
<tr><th><label for="id_subject">Subject:</label></th><td><input id="id_subject" type="text" name=
↪"subject" maxlength="100" value="hello" required></td></tr>
<tr><th><label for="id_message">Message:</label></th><td><input type="text" name="message" id="id_
↪message" value="Hi there" required></td></tr>
<tr><th><label for="id_sender">Sender:</label></th><td><input type="email" name="sender" id="id_
↪sender" value="foo@example.com" required></td></tr>
<tr><th><label for="id_cc_myself">Cc myself:</label></th><td><input type="checkbox" name="cc_myself
↪" id="id_cc_myself" checked></td></tr>

```

This default output is a two-column HTML table, with a `<tr>` for each field. Notice the following:

- For flexibility, the output does not include the `<table>` and `</table>` tags, nor does it include the `<form>` and `</form>` tags or an `<input type="submit">` tag. It's your job to do that.
- Each field type has a default HTML representation. `CharField` is represented by an `<input type="text">` and `EmailField` by an `<input type="email">`. `BooleanField(null=False)` is represented by an `<input type="checkbox">`. Note these are merely sensible defaults; you can specify which HTML to use for a given field by using widgets, which we'll explain shortly.
- The HTML `name` for each tag is taken directly from its attribute name in the `ContactForm` class.
- The text label for each field –e.g. 'Subject:', 'Message:' and 'Cc myself:' is generated from the field name by converting all underscores to spaces and upper-casing the first letter. Again, note these are merely sensible defaults; you can also specify labels manually.
- Each text label is surrounded in an HTML `<label>` tag, which points to the appropriate form field via its `id`. Its `id`, in turn, is generated by prepending 'id_' to the field name. The `id` attributes and `<label>` tags are included in the output by default, to follow best practices, but you can change that behavior.

- The output uses HTML5 syntax, targeting `<!DOCTYPE html>`. For example, it uses boolean attributes such as `checked` rather than the XHTML style of `checked='checked'`.

Although `<table>` output is the default output style when you `print` a form, other output styles are available. Each style is available as a method on a form object, and each rendering method returns a string.

Default rendering

The default rendering when you `print` a form uses the following methods and attributes.

`template_name`

`Form.template_name`

The name of the template rendered if the form is cast into a string, e.g. via `print(form)` or in a template via `{{ form }}`.

By default, a property returning the value of the renderer's `form_template_name`. You may set it as a string template name in order to override that for a particular form class.

In older versions `template_name` defaulted to the string value `'django/forms/default.html'`.

`render()`

`Form.render(template_name=None, context=None, renderer=None)`

The `render` method is called by `__str__` as well as the `Form.as_table()`, `Form.as_p()`, and `Form.as_ul()` methods. All arguments are optional and default to:

- `template_name`: `Form.template_name`
- `context`: Value returned by `Form.get_context()`
- `renderer`: Value returned by `Form.default_renderer`

By passing `template_name` you can customize the template used for just a single call.

`get_context()`

`Form.get_context()`

Return the template context for rendering the form.

The available context is:

- `form`: The bound form.
- `fields`: All bound fields, except the hidden fields.

- `hidden_fields`: All hidden bound fields.
- `errors`: All non field related or hidden field related form errors.

`template_name_label`

`Form.template_name_label`

The template used to render a field's `<label>`, used when calling `BoundField.label_tag()/legend_tag()`. Can be changed per form by overriding this attribute or more generally by overriding the default template, see also [Overriding built-in form templates](#).

Output styles

As well as rendering the form directly, such as in a template with `{{ form }}`, the following helper functions serve as a proxy to `Form.render()` passing a particular `template_name` value.

These helpers are most useful in a template, where you need to override the form renderer or form provided value but cannot pass the additional parameter to `render()`. For example, you can render a form as an unordered list using `{{ form.as_ul }}`.

Each helper pairs a form method with an attribute giving the appropriate template name.

`as_div()`

`Form.template_name_div`

The template used by `as_div()`. Default: `'django/forms/div.html'`.

`Form.as_div()`

`as_div()` renders the form as a series of `<div>` elements, with each `<div>` containing one field, such as:

```
>>> f = ContactForm()
>>> f.as_div()
```

... gives HTML like:

```
<div>
<label for="id_subject">Subject:</label>
<input type="text" name="subject" maxlength="100" required id="id_subject">
</div>
<div>
<label for="id_message">Message:</label>
<input type="text" name="message" required id="id_message">
```

(continues on next page)

(continued from previous page)

```
</div>
<div>
<label for="id_sender">Sender:</label>
<input type="email" name="sender" required id="id_sender">
</div>
<div>
<label for="id_cc_myself">Cc myself:</label>
<input type="checkbox" name="cc_myself" id="id_cc_myself">
</div>
```

Note: Of the framework provided templates and output styles, `as_div()` is recommended over the `as_p()`, `as_table()`, and `as_ul()` versions as the template implements `<fieldset>` and `<legend>` to group related inputs and is easier for screen reader users to navigate.

`as_p()`

`Form.template_name_p`

The template used by `as_p()`. Default: `'django/forms/p.html'`.

`Form.as_p()`

`as_p()` renders the form as a series of `<p>` tags, with each `<p>` containing one field:

```
>>> f = ContactForm()
>>> f.as_p()
'<p><label for="id_subject">Subject:</label> <input id="id_subject" type="text" name="subject"
↳maxlength="100" required</p>\n<p><label for="id_message">Message:</label> <input type="text"
↳name="message" id="id_message" required</p>\n<p><label for="id_sender">Sender:</label> <input
↳type="text" name="sender" id="id_sender" required</p>\n<p><label for="id_cc_myself">Cc myself:</
↳label> <input type="checkbox" name="cc_myself" id="id_cc_myself"></p>'
>>> print(f.as_p())
<p><label for="id_subject">Subject:</label> <input id="id_subject" type="text" name="subject"
↳maxlength="100" required</p>
<p><label for="id_message">Message:</label> <input type="text" name="message" id="id_message"
↳required</p>
<p><label for="id_sender">Sender:</label> <input type="email" name="sender" id="id_sender"
↳required</p>
<p><label for="id_cc_myself">Cc myself:</label> <input type="checkbox" name="cc_myself" id="id_cc_
↳myself"></p>
```

`as_ul()`

`Form.template_name_ul`

The template used by `as_ul()`. Default: `'django/forms/ul.html'`.

`Form.as_ul()`

`as_ul()` renders the form as a series of `<li>` tags, with each `<li>` containing one field. It does not include the `<ul>` or `</ul>`, so that you can specify any HTML attributes on the `<ul>` for flexibility:

```
>>> f = ContactForm()
>>> f.as_ul()
'<li><label for="id_subject">Subject:</label> <input id="id_subject" type="text" name="subject"
↳maxlength="100" required></li>\n<li><label for="id_message">Message:</label> <input type="text"
↳name="message" id="id_message" required></li>\n<li><label for="id_sender">Sender:</label> <input
↳type="email" name="sender" id="id_sender" required></li>\n<li><label for="id_cc_myself">Cc
↳myself:</label> <input type="checkbox" name="cc_myself" id="id_cc_myself"></li>'
>>> print(f.as_ul())
<li><label for="id_subject">Subject:</label> <input id="id_subject" type="text" name="subject"
↳maxlength="100" required></li>
<li><label for="id_message">Message:</label> <input type="text" name="message" id="id_message"
↳required></li>
<li><label for="id_sender">Sender:</label> <input type="email" name="sender" id="id_sender"
↳required></li>
<li><label for="id_cc_myself">Cc myself:</label> <input type="checkbox" name="cc_myself" id="id_cc_
↳myself"></li>
```

`as_table()`

`Form.template_name_table`

The template used by `as_table()`. Default: `'django/forms/table.html'`.

`Form.as_table()`

`as_table()` renders the form as an HTML `<table>`:

```
>>> f = ContactForm()
>>> f.as_table()
'<tr><th><label for="id_subject">Subject:</label></th><td><input id="id_subject" type="text" name=
↳"subject" maxlength="100" required></td></tr>\n<tr><th><label for="id_message">Message:</label></
↳th><td><input type="text" name="message" id="id_message" required></td></tr>\n<tr><th><label for=
↳"id_sender">Sender:</label></th><td><input type="email" name="sender" id="id_sender" required></
↳td></tr>\n<tr><th><label for="id_cc_myself">Cc myself:</label></th><td><input type="checkbox"
↳name="cc_myself" id="id_cc_myself"></td></tr>'
```

(continues on next page)

(continued from previous page)

```
>>> print(f)
<tr><th><label for="id_subject">Subject:</label></th><td><input id="id_subject" type="text" name=
↪ "subject" maxlength="100" required></td></tr>
<tr><th><label for="id_message">Message:</label></th><td><input type="text" name="message" id="id_
↪ message" required></td></tr>
<tr><th><label for="id_sender">Sender:</label></th><td><input type="email" name="sender" id="id_
↪ sender" required></td></tr>
<tr><th><label for="id_cc_myself">Cc myself:</label></th><td><input type="checkbox" name="cc_myself
↪ " id="id_cc_myself"></td></tr>
```

Styling required or erroneous form rows

`Form.error_css_class`

`Form.required_css_class`

It's pretty common to style form rows and fields that are required or have errors. For example, you might want to present required form rows in bold and highlight errors in red.

The `Form` class has a couple of hooks you can use to add `class` attributes to required rows or to rows with errors: set the `Form.error_css_class` and/or `Form.required_css_class` attributes:

```
from django import forms

class ContactForm(forms.Form):
    error_css_class = "error"
    required_css_class = "required"

    # ... and the rest of your fields here
```

Once you've done that, rows will be given "error" and/or "required" classes, as needed. The HTML will look something like:

```
>>> f = ContactForm(data)
>>> print(f.as_table())
<tr class="required"><th><label class="required" for="id_subject">Subject:</label> ...
<tr class="required"><th><label class="required" for="id_message">Message:</label> ...
<tr class="required error"><th><label class="required" for="id_sender">Sender:</label> ...
<tr><th><label for="id_cc_myself">Cc myself:</label> ...
>>> f["subject"].label_tag()
<label class="required" for="id_subject">Subject:</label>
>>> f["subject"].legend_tag()
```

(continues on next page)

(continued from previous page)

```

<legend class="required" for="id_subject">Subject:</legend>
>>> f["subject"].label_tag(attrs={"class": "foo"})
<label for="id_subject" class="foo required">Subject:</label>
>>> f["subject"].legend_tag(attrs={"class": "foo"})
<legend for="id_subject" class="foo required">Subject:</legend>

```

Configuring form elements' HTML id attributes and <label> tags

Form.auto_id

By default, the form rendering methods include:

- HTML id attributes on the form elements.
- The corresponding <label> tags around the labels. An HTML <label> tag designates which label text is associated with which form element. This small enhancement makes forms more usable and more accessible to assistive devices. It's always a good idea to use <label> tags.

The id attribute values are generated by prepending id_ to the form field names. This behavior is configurable, though, if you want to change the id convention or remove HTML id attributes and <label> tags entirely.

Use the auto_id argument to the Form constructor to control the id and label behavior. This argument must be True, False or a string.

If auto_id is False, then the form output will not include <label> tags nor id attributes:

```

>>> f = ContactForm(auto_id=False)
>>> print(f.as_div())
<div>Subject:<input type="text" name="subject" maxlength="100" required></div>
<div>Message:<textarea name="message" cols="40" rows="10" required></textarea></div>
<div>Sender:<input type="email" name="sender" required></div>
<div>Cc myself:<input type="checkbox" name="cc_myself"></div>

```

If auto_id is set to True, then the form output will include <label> tags and will use the field name as its id for each form field:

```

>>> f = ContactForm(auto_id=True)
>>> print(f.as_div())
<div><label for="subject">Subject:</label><input type="text" name="subject" maxlength="100"
↪required id="subject"></div>
<div><label for="message">Message:</label><textarea name="message" cols="40" rows="10" required id=
↪"message"></textarea></div>
<div><label for="sender">Sender:</label><input type="email" name="sender" required id="sender"></
↪div>

```

(continues on next page)

(continued from previous page)

```
<div><label for="cc_myself">Cc myself:</label><input type="checkbox" name="cc_myself" id="cc_myself"
↪"></div>
```

If `auto_id` is set to a string containing the format character `'%s'`, then the form output will include `<label>` tags, and will generate `id` attributes based on the format string. For example, for a format string `'field_%s'`, a field named `subject` will get the `id` value `'field_subject'`. Continuing our example:

```
>>> f = ContactForm(auto_id="id_for_%s")
>>> print(f.as_div())
<div><label for="id_for_subject">Subject:</label><input type="text" name="subject" maxlength="100"
↪required id="id_for_subject"></div>
<div><label for="id_for_message">Message:</label><textarea name="message" cols="40" rows="10"
↪required id="id_for_message"></textarea></div>
<div><label for="id_for_sender">Sender:</label><input type="email" name="sender" required id="id_
↪for_sender"></div>
<div><label for="id_for_cc_myself">Cc myself:</label><input type="checkbox" name="cc_myself" id=
↪"id_for_cc_myself"></div>
```

If `auto_id` is set to any other true value –such as a string that doesn't include `%s`–then the library will act as if `auto_id` is `True`.

By default, `auto_id` is set to the string `'id_%s'`.

Form.label_suffix

A translatable string (defaults to a colon (`:`) in English) that will be appended after any label name when a form is rendered.

It's possible to customize that character, or omit it entirely, using the `label_suffix` parameter:

```
>>> f = ContactForm(auto_id="id_for_%s", label_suffix="")
>>> print(f.as_div())
<div><label for="id_for_subject">Subject</label><input type="text" name="subject" maxlength="100"
↪required id="id_for_subject"></div>
<div><label for="id_for_message">Message</label><textarea name="message" cols="40" rows="10"
↪required id="id_for_message"></textarea></div>
<div><label for="id_for_sender">Sender</label><input type="email" name="sender" required id="id_
↪for_sender"></div>
<div><label for="id_for_cc_myself">Cc myself</label><input type="checkbox" name="cc_myself" id="id_
↪for_cc_myself"></div>
>>> f = ContactForm(auto_id="id_for_%s", label_suffix=" ->")
>>> print(f.as_div())
<div><label for="id_for_subject">Subject:</label><input type="text" name="subject" maxlength="100"
↪required id="id_for_subject"></div>
<div><label for="id_for_message">Message -&gt;</label><textarea name="message" cols="40" rows="10"
↪required id="id_for_message"></div>
```

(continues on next page)

(continued from previous page)

```

<input required id="id_for_message"></textarea></div>
<div><label for="id_for_sender">Sender -&gt;</label><input type="email" name="sender" required id=
<input id="id_for_sender"></div>
<div><label for="id_for_cc_myself">Cc myself -&gt;</label><input type="checkbox" name="cc_myself"
<input id="id_for_cc_myself"></div>

```

Note that the label suffix is added only if the last character of the label isn't a punctuation character (in English, those are ., !, ? or :).

Fields can also define their own `label_suffix`. This will take precedence over `Form.label_suffix`. The suffix can also be overridden at runtime using the `label_suffix` parameter to `label_tag()`/`legend_tag()`.

`Form.use_required_attribute`

When set to `True` (the default), required form fields will have the `required` HTML attribute.

`Formsets` instantiate forms with `use_required_attribute=False` to avoid incorrect browser validation when adding and deleting forms from a formset.

Configuring the rendering of a form's widgets

`Form.default_renderer`

Specifies the `renderer` to use for the form. Defaults to `None` which means to use the default renderer specified by the `FORM_RENDERER` setting.

You can set this as a class attribute when declaring your form or use the `renderer` argument to `Form.__init__()`. For example:

```

from django import forms

class MyForm(forms.Form):
    default_renderer = MyRenderer()

```

or:

```
form = MyForm(renderer=MyRenderer())
```

Notes on field ordering

In the `as_p()`, `as_ul()` and `as_table()` shortcuts, the fields are displayed in the order in which you define them in your form class. For example, in the `ContactForm` example, the fields are defined in the order `subject`, `message`, `sender`, `cc_myself`. To reorder the HTML output, change the order in which those fields are listed in the class.

There are several other ways to customize the order:

`Form.field_order`

By default `Form.field_order=None`, which retains the order in which you define the fields in your form class. If `field_order` is a list of field names, the fields are ordered as specified by the list and remaining fields are appended according to the default order. Unknown field names in the list are ignored. This makes it possible to disable a field in a subclass by setting it to `None` without having to redefine ordering.

You can also use the `Form.field_order` argument to a *Form* to override the field order. If a *Form* defines *field_order* and you include `field_order` when instantiating the Form, then the latter `field_order` will have precedence.

`Form.order_fields(field_order)`

You may rearrange the fields any time using `order_fields()` with a list of field names as in *field_order*.

How errors are displayed

If you render a bound Form object, the act of rendering will automatically run the form's validation if it hasn't already happened, and the HTML output will include the validation errors as a `<ul class="errorlist">` near the field. The particular positioning of the error messages depends on the output method you're using:

```
>>> data = {
...     "subject": "",
...     "message": "Hi there",
...     "sender": "invalid email address",
...     "cc_myself": True,
... }
>>> f = ContactForm(data, auto_id=False)
>>> print(f.as_div())
<div>Subject:<ul class="errorlist"><li>This field is required.</li></ul><input type="text" name=
↪"subject" maxlength="100" required></div>
<div>Message:<textarea name="message" cols="40" rows="10" required>Hi there</textarea></div>
<div>Sender:<ul class="errorlist"><li>Enter a valid email address.</li></ul><input type="email"
↪name="sender" value="invalid email address" required></div>
<div>Cc myself:<input type="checkbox" name="cc_myself" checked></div>
>>> print(f.as_table())
```

(continues on next page)

(continued from previous page)

```

<tr><th>Subject:</th><td><ul class="errorlist"><li>This field is required.</li></ul><input type=
↪ "text" name="subject" maxlength="100" required></td></tr>
<tr><th>Message:</th><td><textarea name="message" cols="40" rows="10" required></textarea></td></
↪ tr>
<tr><th>Sender:</th><td><ul class="errorlist"><li>Enter a valid email address.</li></ul><input
↪ type="email" name="sender" value="invalid email address" required></td></tr>
<tr><th>Cc myself:</th><td><input checked type="checkbox" name="cc_myself"></td></tr>
>>> print(f.as_ul())
<li><ul class="errorlist"><li>This field is required.</li></ul>Subject: <input type="text" name=
↪ "subject" maxlength="100" required></li>
<li>Message: <textarea name="message" cols="40" rows="10" required></textarea></li>
<li><ul class="errorlist"><li>Enter a valid email address.</li></ul>Sender: <input type="email"
↪ name="sender" value="invalid email address" required></li>
<li>Cc myself: <input checked type="checkbox" name="cc_myself"></li>
>>> print(f.as_p())
<p><ul class="errorlist"><li>This field is required.</li></ul></p>
<p>Subject: <input type="text" name="subject" maxlength="100" required></p>
<p>Message: <textarea name="message" cols="40" rows="10" required></textarea></p>
<p><ul class="errorlist"><li>Enter a valid email address.</li></ul></p>
<p>Sender: <input type="email" name="sender" value="invalid email address" required></p>
<p>Cc myself: <input checked type="checkbox" name="cc_myself"></p>

```

Customizing the error list format

class `ErrorList` (`initlist=None`, `error_class=None`, `renderer=None`)

By default, forms use `django.forms.utils.ErrorList` to format validation errors. `ErrorList` is a list like object where `initlist` is the list of errors. In addition this class has the following attributes and methods.

`error_class`

The CSS classes to be used when rendering the error list. Any provided classes are added to the default `errorlist` class.

`renderer`

Specifies the `renderer` to use for `ErrorList`. Defaults to `None` which means to use the default renderer specified by the `FORM_RENDERER` setting.

`template_name`

The name of the template used when calling `__str__` or `render()`. By default this is `'django/forms/errors/list/default.html'` which is a proxy for the `'ul.html'` template.

`template_name_text`

The name of the template used when calling `as_text()`. By default this is `'django/forms/errors/list/text.html'`. This template renders the errors as a list of bullet points.

`template_name_ul`

The name of the template used when calling `as_ul()`. By default this is `'django/forms/errors/list/ul.html'`. This template renders the errors in `<li>` tags with a wrapping `<ul>` with the CSS classes as defined by `error_class`.

`get_context()`

Return context for rendering of errors in a template.

The available context is:

- `errors` : A list of the errors.
- `error_class` : A string of CSS classes.

`render(template_name=None, context=None, renderer=None)`

The render method is called by `__str__` as well as by the `as_ul()` method.

All arguments are optional and will default to:

- `template_name`: Value returned by `template_name`
- `context`: Value returned by `get_context()`
- `renderer`: Value returned by `renderer`

`as_text()`

Renders the error list using the template defined by `template_name_text`.

`as_ul()`

Renders the error list using the template defined by `template_name_ul`.

If you'd like to customize the rendering of errors this can be achieved by overriding the `template_name` attribute or more generally by overriding the default template, see also [Overriding built-in form templates](#).

Deprecated since version 4.0: The ability to return a `str` when calling the `__str__` method is deprecated. Use the template engine instead which returns a `SafeString`.

More granular output

The `as_p()`, `as_ul()`, and `as_table()` methods are shortcuts –they're not the only way a form object can be displayed.

`class BoundField`

Used to display HTML or access attributes for a single field of a `Form` instance.

The `__str__()` method of this object displays the HTML for this field.

To retrieve a single `BoundField`, use dictionary lookup syntax on your form using the field's name as the key:

```
>>> form = ContactForm()
>>> print(form["subject"])
<input id="id_subject" type="text" name="subject" maxlength="100" required>
```

To retrieve all `BoundField` objects, iterate the form:

```
>>> form = ContactForm()
>>> for boundfield in form:
...     print(boundfield)
...
<input id="id_subject" type="text" name="subject" maxlength="100" required>
<input type="text" name="message" id="id_message" required>
<input type="email" name="sender" id="id_sender" required>
<input type="checkbox" name="cc_myself" id="id_cc_myself">
```

The field-specific output honors the form object's `auto_id` setting:

```
>>> f = ContactForm(auto_id=False)
>>> print(f["message"])
<input type="text" name="message" required>
>>> f = ContactForm(auto_id="id_%s")
>>> print(f["message"])
<input type="text" name="message" id="id_message" required>
```

Attributes of `BoundField`

`BoundField.auto_id`

The HTML ID attribute for this `BoundField`. Returns an empty string if `Form.auto_id` is `False`.

`BoundField.data`

This property returns the data for this `BoundField` extracted by the widget's `value_from_datadict()` method, or `None` if it wasn't given:

```
>>> unbound_form = ContactForm()
>>> print(unbound_form["subject"].data)
None
>>> bound_form = ContactForm(data={"subject": "My Subject"})
>>> print(bound_form["subject"].data)
My Subject
```

`BoundField.errors`

A list-like object that is displayed as an HTML `<ul class="errorlist">` when printed:

```
>>> data = {"subject": "hi", "message": "", "sender": "", "cc_myself": ""}
>>> f = ContactForm(data, auto_id=False)
>>> print(f["message"])
<input type="text" name="message" required>
>>> f["message"].errors
['This field is required.']
>>> print(f["message"].errors)
<ul class="errorlist"><li>This field is required.</li></ul>
>>> f["subject"].errors
[]
>>> print(f["subject"].errors)

>>> str(f["subject"].errors)
''
```

BoundField.field

The form *Field* instance from the form class that this *BoundField* wraps.

BoundField.form

The *Form* instance this *BoundField* is bound to.

BoundField.help_text

The *help_text* of the field.

BoundField.html_name

The name that will be used in the widget's HTML *name* attribute. It takes the form *prefix* into account.

BoundField.id_for_label

Use this property to render the ID of this field. For example, if you are manually constructing a `<label>` in your template (despite the fact that `label_tag()`/`legend_tag()` will do this for you):

```
<label for="{{ form.my_field.id_for_label }}">...</label>{{ my_field }}
```

By default, this will be the field's name prefixed by `id_` ("id_my_field" for the example above). You may modify the ID by setting *attrs* on the field's widget. For example, declaring a field like this:

```
my_field = forms.CharField(widget=forms.TextInput(attrs={"id": "myFIELD"}))
```

and using the template above, would render something like:

```
<label for="myFIELD">...</label><input id="myFIELD" type="text" name="my_field" required>
```

BoundField.initial

Use *BoundField.initial* to retrieve initial data for a form field. It retrieves the data from *Form.initial* if present, otherwise trying *Field.initial*. Callable values are evaluated. See [Initial form values](#) for more examples.

BoundField.initial caches its return value, which is useful especially when dealing with callables whose return values can change (e.g. `datetime.now` or `uuid.uuid4`):

```
>>> from datetime import datetime
>>> class DatedCommentForm(CommentForm):
...     created = forms.DateTimeField(initial=datetime.now)
...
>>> f = DatedCommentForm()
>>> f["created"].initial
datetime.datetime(2021, 7, 27, 9, 5, 54)
>>> f["created"].initial
datetime.datetime(2021, 7, 27, 9, 5, 54)
```

Using *BoundField.initial* is recommended over *get_initial_for_field()*.

BoundField.is_hidden

Returns True if this *BoundField*'s widget is hidden.

BoundField.label

The *label* of the field. This is used in *label_tag()/legend_tag()*.

BoundField.name

The name of this field in the form:

```
>>> f = ContactForm()
>>> print(f["subject"].name)
subject
>>> print(f["message"].name)
message
```

BoundField.use_fieldset

Returns the value of this *BoundField* widget's *use_fieldset* attribute.

BoundField.widget_type

Returns the lowercased class name of the wrapped field's widget, with any trailing *input* or *widget* removed. This may be used when building forms where the layout is dependent upon the widget type. For example:

```
{% for field in form %}
    {% if field.widget_type == 'checkbox' %}
        # render one way
    {% else %}
        # render another way
    {% endif %}
{% endfor %}
```

Methods of `BoundField`

`BoundField.as_hidden(attrs=None, **kwargs)`

Returns a string of HTML for representing this as an `<input type="hidden">`.

****kwargs** are passed to `as_widget()`.

This method is primarily used internally. You should use a widget instead.

`BoundField.as_widget(widget=None, attrs=None, only_initial=False)`

Renders the field by rendering the passed widget, adding any HTML attributes passed as **attrs**. If no widget is specified, then the field's default widget will be used.

only_initial is used by Django internals and should not be set explicitly.

`BoundField.css_classes(extra_classes=None)`

When you use Django's rendering shortcuts, CSS classes are used to indicate required form fields or fields that contain errors. If you're manually rendering a form, you can access these CSS classes using the `css_classes` method:

```
>>> f = ContactForm(data={"message": ""})
>>> f["message"].css_classes()
'required'
```

If you want to provide some additional classes in addition to the error and required classes that may be required, you can provide those classes as an argument:

```
>>> f = ContactForm(data={"message": ""})
>>> f["message"].css_classes("foo bar")
'foo bar required'
```

`BoundField.label_tag(contents=None, attrs=None, label_suffix=None, tag=None)`

Renders a label tag for the form field using the template specified by `Form.template_name_label`.

The available context is:

- **field**: This instance of the `BoundField`.
- **contents**: By default a concatenated string of `BoundField.label` and `Form.label_suffix` (or `Field.label_suffix`, if set). This can be overridden by the **contents** and **label_suffix** arguments.
- **attrs**: A dict containing `for`, `Form.required_css_class`, and `id`. `id` is generated by the field's widget `attrs` or `BoundField.auto_id`. Additional attributes can be provided by the **attrs** argument.
- **use_tag**: A boolean which is `True` if the label has an `id`. If `False` the default template omits the tag.

- `tag`: An optional string to customize the tag, defaults to `label`.

Tip: In your template `field` is the instance of the `BoundField`. Therefore `field.field` accesses `BoundField.field` being the field you declare, e.g. `forms.CharField`.

To separately render the label tag of a form field, you can call its `label_tag()` method:

```
>>> f = ContactForm(data={"message": ""})
>>> print(f["message"].label_tag())
<label for="id_message">Message:</label>
```

If you'd like to customize the rendering this can be achieved by overriding the `Form.template_name_label` attribute or more generally by overriding the default template, see also [Overriding built-in form templates](#).

The `tag` argument was added.

`BoundField.legend_tag(contents=None, attrs=None, label_suffix=None)`

Calls `label_tag()` with `tag='legend'` to render the label with `<legend>` tags. This is useful when rendering radio and multiple checkbox widgets where `<legend>` may be more appropriate than a `<label>`.

`BoundField.value()`

Use this method to render the raw value of this field as it would be rendered by a `Widget`:

```
>>> initial = {"subject": "welcome"}
>>> unbound_form = ContactForm(initial=initial)
>>> bound_form = ContactForm(data={"subject": "hi"}, initial=initial)
>>> print(unbound_form["subject"].value())
welcome
>>> print(bound_form["subject"].value())
hi
```

Customizing BoundField

If you need to access some additional information about a form field in a template and using a subclass of `Field` isn't sufficient, consider also customizing `BoundField`.

A custom form field can override `get_bound_field()`:

`Field.get_bound_field(form, field_name)`

Takes an instance of `Form` and the name of the field. The return value will be used when accessing the field in a template. Most likely it will be an instance of a subclass of `BoundField`.

If you have a `GPSCoordinatesField`, for example, and want to be able to access additional information about the coordinates in a template, this could be implemented as follows:

```
class GPSCoordinatesBoundField(BoundField):
    @property
    def country(self):
        """
        Return the country the coordinates lie in or None if it can't be
        determined.
        """
        value = self.value()
        if value:
            return get_country_from_coordinates(value)
        else:
            return None

class GPSCoordinatesField(Field):
    def get_bound_field(self, form, field_name):
        return GPSCoordinatesBoundField(form, self, field_name)
```

Now you can access the country in a template with `{{ form.coordinates.country }}`.

Binding uploaded files to a form

Dealing with forms that have `FileField` and `ImageField` fields is a little more complicated than a normal form.

Firstly, in order to upload files, you'll need to make sure that your `<form>` element correctly defines the enctype as "multipart/form-data":

```
<form enctype="multipart/form-data" method="post" action="/foo/">
```

Secondly, when you use the form, you need to bind the file data. File data is handled separately to normal form data, so when your form contains a `FileField` and `ImageField`, you will need to specify a second argument when you bind your form. So if we extend our `ContactForm` to include an `ImageField` called `mugshot`, we need to bind the file data containing the mugshot image:

```
# Bound form with an image field
>>> from django.core.files.uploadedfile import SimpleUploadedFile
>>> data = {
...     "subject": "hello",
...     "message": "Hi there",
...     "sender": "foo@example.com",
...     "cc_myself": True,
... }
```

(continues on next page)

(continued from previous page)

```
>>> file_data = {"mugshot": SimpleUploadedFile("face.jpg", b"file data")}
>>> f = ContactFormWithMugshot(data, file_data)
```

In practice, you will usually specify `request.FILES` as the source of file data (just like you use `request.POST` as the source of form data):

```
# Bound form with an image field, data from the request
>>> f = ContactFormWithMugshot(request.POST, request.FILES)
```

Constructing an unbound form is the same as always –omit both form data and file data:

```
# Unbound form with an image field
>>> f = ContactFormWithMugshot()
```

Testing for multipart forms

`Form.is_multipart()`

If you're writing reusable views or templates, you may not know ahead of time whether your form is a multipart form or not. The `is_multipart()` method tells you whether the form requires multipart encoding for submission:

```
>>> f = ContactFormWithMugshot()
>>> f.is_multipart()
True
```

Here's an example of how you might use this in a template:

```
{% if form.is_multipart %}
    <form enctype="multipart/form-data" method="post" action="/foo/">
{% else %}
    <form method="post" action="/foo/">
{% endif %}
{{ form }}
</form>
```

Subclassing forms

If you have multiple Form classes that share fields, you can use subclassing to remove redundancy.

When you subclass a custom Form class, the resulting subclass will include all fields of the parent class(es), followed by the fields you define in the subclass.

In this example, `ContactFormWithPriority` contains all the fields from `ContactForm`, plus an additional field, `priority`. The `ContactForm` fields are ordered first:

```
>>> class ContactFormWithPriority(ContactForm):
...     priority = forms.CharField()
...
>>> f = ContactFormWithPriority(auto_id=False)
>>> print(f.as_div())
<div>Subject:<input type="text" name="subject" maxlength="100" required></div>
<div>Message:<textarea name="message" cols="40" rows="10" required></textarea></div>
<div>Sender:<input type="email" name="sender" required></div>
<div>Cc myself:<input type="checkbox" name="cc_myself"></div>
<div>Priority:<input type="text" name="priority" required></div>
```

It's possible to subclass multiple forms, treating forms as mixins. In this example, `BeatleForm` subclasses both `PersonForm` and `InstrumentForm` (in that order), and its field list includes the fields from the parent classes:

```
>>> from django import forms
>>> class PersonForm(forms.Form):
...     first_name = forms.CharField()
...     last_name = forms.CharField()
...
>>> class InstrumentForm(forms.Form):
...     instrument = forms.CharField()
...
>>> class BeatleForm(InstrumentForm, PersonForm):
...     haircut_type = forms.CharField()
...
>>> b = BeatleForm(auto_id=False)
>>> print(b.as_div())
<div>First name:<input type="text" name="first_name" required></div>
<div>Last name:<input type="text" name="last_name" required></div>
<div>Instrument:<input type="text" name="instrument" required></div>
<div>Haircut type:<input type="text" name="haircut_type" required></div>
```

It's possible to declaratively remove a `Field` inherited from a parent class by setting the name of the field to `None` on the subclass. For example:

```
>>> from django import forms

>>> class ParentForm(forms.Form):
...     name = forms.CharField()
...     age = forms.IntegerField()
...

>>> class ChildForm(ParentForm):
...     name = None
...

>>> list(ChildForm().fields)
['age']
```

Prefixes for forms

Form.prefix

You can put several Django forms inside one `<form>` tag. To give each Form its own namespace, use the `prefix` keyword argument:

```
>>> mother = PersonForm(prefix="mother")
>>> father = PersonForm(prefix="father")
>>> print(mother.as_div())
<div><label for="id_mother-first_name">First name:</label><input type="text" name="mother-first_
↵name" required id="id_mother-first_name"></div>
<div><label for="id_mother-last_name">Last name:</label><input type="text" name="mother-last_name"
↵required id="id_mother-last_name"></div>
>>> print(father.as_div())
<div><label for="id_father-first_name">First name:</label><input type="text" name="father-first_
↵name" required id="id_father-first_name"></div>
<div><label for="id_father-last_name">Last name:</label><input type="text" name="father-last_name"
↵required id="id_father-last_name"></div>
```

The prefix can also be specified on the form class:

```
>>> class PersonForm(forms.Form):
...     ...
...     prefix = "person"
... 
```

6.12.2 Form fields

```
class Field(**kwargs)
```

When you create a `Form` class, the most important part is defining the fields of the form. Each field has custom validation logic, along with a few other hooks.

```
Field.clean(value)
```

Although the primary way you'll use `Field` classes is in `Form` classes, you can also instantiate them and use them directly to get a better idea of how they work. Each `Field` instance has a `clean()` method, which takes a single argument and either raises a `django.core.exceptions.ValidationError` exception or returns the clean value:

```
>>> from django import forms
>>> f = forms.EmailField()
>>> f.clean("foo@example.com")
'foo@example.com'
>>> f.clean("invalid email address")
Traceback (most recent call last):
...
ValidationError: ['Enter a valid email address.']
```

Core field arguments

Each `Field` class constructor takes at least these arguments. Some `Field` classes take additional, field-specific arguments, but the following should always be accepted:

`required`

```
Field.required
```

By default, each `Field` class assumes the value is required, so if you pass an empty value –either `None` or the empty string (`""`) –then `clean()` will raise a `ValidationError` exception:

```
>>> from django import forms
>>> f = forms.CharField()
>>> f.clean("foo")
'foo'
>>> f.clean("")
Traceback (most recent call last):
...
ValidationError: ['This field is required.']
>>> f.clean(None)
```

(continues on next page)

(continued from previous page)

```
Traceback (most recent call last):
...
ValidationError: ['This field is required.']
>>> f.clean(" ")
''
>>> f.clean(0)
'0'
>>> f.clean(True)
'True'
>>> f.clean(False)
'False'
```

To specify that a field is not required, pass `required=False` to the `Field` constructor:

```
>>> f = forms.CharField(required=False)
>>> f.clean("foo")
'foo'
>>> f.clean("")
''
>>> f.clean(None)
''
>>> f.clean(0)
'0'
>>> f.clean(True)
'True'
>>> f.clean(False)
'False'
```

If a `Field` has `required=False` and you pass `clean()` an empty value, then `clean()` will return a normalized empty value rather than raising `ValidationError`. For `CharField`, this will return `empty_value` which defaults to an empty string. For other `Field` classes, it might be `None`. (This varies from field to field.)

Widgets of required form fields have the `required` HTML attribute. Set the `Form.use_required_attribute` attribute to `False` to disable it. The `required` attribute isn't included on forms of formsets because the browser validation may not be correct when adding and deleting formsets.

label

Field.label

The `label` argument lets you specify the “human-friendly” label for this field. This is used when the `Field` is displayed in a `Form`.

As explained in “Outputting forms as HTML” above, the default label for a `Field` is generated from the field name by converting all underscores to spaces and upper-casing the first letter. Specify `label` if that default behavior doesn’t result in an adequate label.

Here’s a full example `Form` that implements `label` for two of its fields. We’ve specified `auto_id=False` to simplify the output:

```
>>> from django import forms
>>> class CommentForm(forms.Form):
...     name = forms.CharField(label="Your name")
...     url = forms.URLField(label="Your website", required=False)
...     comment = forms.CharField()
...
>>> f = CommentForm(auto_id=False)
>>> print(f)
<tr><th>Your name:</th><td><input type="text" name="name" required></td></tr>
<tr><th>Your website:</th><td><input type="url" name="url"></td></tr>
<tr><th>Comment:</th><td><input type="text" name="comment" required></td></tr>
```

label_suffix

Field.label_suffix

The `label_suffix` argument lets you override the form’s `label_suffix` on a per-field basis:

```
>>> class ContactForm(forms.Form):
...     age = forms.IntegerField()
...     nationality = forms.CharField()
...     captcha_answer = forms.IntegerField(label="2 + 2", label_suffix=" =")
...
>>> f = ContactForm(label_suffix=" ?")
>>> print(f.as_p())
<p><label for="id_age">Age?</label> <input id="id_age" name="age" type="number" required></p>
<p><label for="id_nationality">Nationality?</label> <input id="id_nationality" name="nationality"
↵ type="text" required></p>
<p><label for="id_captcha_answer">2 + 2 =</label> <input id="id_captcha_answer" name="captcha_
↵ answer" type="number" required></p>
```

`initial`

`Field.initial`

The `initial` argument lets you specify the initial value to use when rendering this `Field` in an unbound `Form`.

To specify dynamic initial data, see the `Form.initial` parameter.

The use-case for this is when you want to display an “empty” form in which a field is initialized to a particular value. For example:

```
>>> from django import forms
>>> class CommentForm(forms.Form):
...     name = forms.CharField(initial="Your name")
...     url = forms.URLField(initial="http://")
...     comment = forms.CharField()
...
>>> f = CommentForm(auto_id=False)
>>> print(f)
<tr><th>Name:</th><td><input type="text" name="name" value="Your name" required></td></tr>
<tr><th>Url:</th><td><input type="url" name="url" value="http://" required></td></tr>
<tr><th>Comment:</th><td><input type="text" name="comment" required></td></tr>
```

You may be thinking, why not just pass a dictionary of the initial values as data when displaying the form? Well, if you do that, you’ ll trigger validation, and the HTML output will include any validation errors:

```
>>> class CommentForm(forms.Form):
...     name = forms.CharField()
...     url = forms.URLField()
...     comment = forms.CharField()
...
>>> default_data = {"name": "Your name", "url": "http://"}
>>> f = CommentForm(default_data, auto_id=False)
>>> print(f)
<tr><th>Name:</th><td><input type="text" name="name" value="Your name" required></td></tr>
<tr><th>Url:</th><td><ul class="errorlist"><li>Enter a valid URL.</li></ul><input type="url" name=
↪ "url" value="http://" required></td></tr>
<tr><th>Comment:</th><td><ul class="errorlist"><li>This field is required.</li></ul><input type=
↪ "text" name="comment" required></td></tr>
```

This is why `initial` values are only displayed for unbound forms. For bound forms, the HTML output will use the bound data.

Also note that `initial` values are not used as “fallback” data in validation if a particular field’ s value is not given. `initial` values are only intended for initial form display:

```
>>> class CommentForm(forms.Form):
...     name = forms.CharField(initial="Your name")
...     url = forms.URLField(initial="http://")
...     comment = forms.CharField()
...
>>> data = {"name": "", "url": "", "comment": "Foo"}
>>> f = CommentForm(data)
>>> f.is_valid()
False
# The form does not fall back to using the initial values.
>>> f.errors
{'url': ['This field is required.'], 'name': ['This field is required.']}
```

Instead of a constant, you can also pass any callable:

```
>>> import datetime
>>> class DateForm(forms.Form):
...     day = forms.DateField(initial=datetime.date.today)
...
>>> print(DateForm())
<tr><th>Day:</th><td><input type="text" name="day" value="12/23/2008" required><td></tr>
```

The callable will be evaluated only when the unbound form is displayed, not when it is defined.

widget

Field.widget

The `widget` argument lets you specify a `Widget` class to use when rendering this `Field`. See [Widgets](#) for more information.

help_text

Field.help_text

The `help_text` argument lets you specify descriptive text for this `Field`. If you provide `help_text`, it will be displayed next to the `Field` when the `Field` is rendered by one of the convenience `Form` methods (e.g., `as_ul()`).

Like the model field's `help_text`, this value isn't HTML-escaped in automatically-generated forms.

Here's a full example `Form` that implements `help_text` for two of its fields. We've specified `auto_id=False` to simplify the output:

```
>>> from django import forms
>>> class HelpTextContactForm(forms.Form):
...     subject = forms.CharField(max_length=100, help_text="100 characters max.")
...     message = forms.CharField()
...     sender = forms.EmailField(help_text="A valid email address, please.")
...     cc_myself = forms.BooleanField(required=False)
...
>>> f = HelpTextContactForm(auto_id=False)
>>> print(f.as_table())
<tr><th>Subject:</th><td><input type="text" name="subject" maxlength="100" required><br><span class="helptext">100 characters max.</span></td></tr>
<tr><th>Message:</th><td><input type="text" name="message" required></td></tr>
<tr><th>Sender:</th><td><input type="email" name="sender" required><br>A valid email address, please.</td></tr>
<tr><th>Cc myself:</th><td><input type="checkbox" name="cc_myself"></td></tr>
>>> print(f.as_ul())
<li>Subject: <input type="text" name="subject" maxlength="100" required> <span class="helptext">100 characters max.</span></li>
<li>Message: <input type="text" name="message" required></li>
<li>Sender: <input type="email" name="sender" required> A valid email address, please.</li>
<li>Cc myself: <input type="checkbox" name="cc_myself"></li>
>>> print(f.as_p())
<p>Subject: <input type="text" name="subject" maxlength="100" required> <span class="helptext">100 characters max.</span></p>
<p>Message: <input type="text" name="message" required></p>
<p>Sender: <input type="email" name="sender" required> A valid email address, please.</p>
<p>Cc myself: <input type="checkbox" name="cc_myself"></p>
```

error_messages

Field.error_messages

The `error_messages` argument lets you override the default messages that the field will raise. Pass in a dictionary with keys matching the error messages you want to override. For example, here is the default error message:

```
>>> from django import forms
>>> generic = forms.CharField()
>>> generic.clean("")
Traceback (most recent call last):
...
ValidationError: ['This field is required.']
```

And here is a custom error message:

```
>>> name = forms.CharField(error_messages={"required": "Please enter your name"})
>>> name.clean("")
Traceback (most recent call last):
...
ValidationError: ['Please enter your name']
```

In the [built-in Field classes](#) section below, each `Field` defines the error message keys it uses.

`validators`

`Field.validators`

The `validators` argument lets you provide a list of validation functions for this field.

See the [validators documentation](#) for more information.

`localize`

`Field.localize`

The `localize` argument enables the localization of form data input, as well as the rendered output.

See the [format localization](#) documentation for more information.

`disabled`

`Field.disabled`

The `disabled` boolean argument, when set to `True`, disables a form field using the `disabled` HTML attribute so that it won't be editable by users. Even if a user tampers with the field's value submitted to the server, it will be ignored in favor of the value from the form's initial data.

Checking if the field data has changed

`has_changed()`

`Field.has_changed()`

The `has_changed()` method is used to determine if the field value has changed from the initial value. Returns `True` or `False`.

See the [Form.has_changed\(\)](#) documentation for more information.

Built-in Field classes

Naturally, the `forms` library comes with a set of `Field` classes that represent common validation needs. This section documents each built-in field.

For each field, we describe the default widget used if you don't specify `widget`. We also specify the value returned when you provide an empty value (see the section on `required` above to understand what that means).

`BooleanField`

```
class BooleanField(**kwargs)
```

- Default widget: *CheckboxInput*
- Empty value: `False`
- Normalizes to: A Python `True` or `False` value.
- Validates that the value is `True` (e.g. the check box is checked) if the field has `required=True`.
- Error message keys: `required`

Note: Since all `Field` subclasses have `required=True` by default, the validation condition here is important. If you want to include a boolean in your form that can be either `True` or `False` (e.g. a checked or unchecked checkbox), you must remember to pass in `required=False` when creating the `BooleanField`.

`CharField`

```
class CharField(**kwargs)
```

- Default widget: *TextInput*
- Empty value: Whatever you've given as *empty_value*.
- Normalizes to: A string.
- Uses *MaxLengthValidator* and *MinLengthValidator* if `max_length` and `min_length` are provided. Otherwise, all inputs are valid.
- Error message keys: `required`, `max_length`, `min_length`

Has the following optional arguments for validation:

`max_length`

min_length

If provided, these arguments ensure that the string is at most or at least the given length.

strip

If `True` (default), the value will be stripped of leading and trailing whitespace.

empty_value

The value to use to represent “empty”. Defaults to an empty string.

ChoiceField

```
class ChoiceField(**kwargs)
```

- Default widget: *Select*
- Empty value: `''` (an empty string)
- Normalizes to: A string.
- Validates that the given value exists in the list of choices.
- Error message keys: `required`, `invalid_choice`

The `invalid_choice` error message may contain `%(value)s`, which will be replaced with the selected choice.

Takes one extra argument:

choices

Either an *iterable* of 2-tuples to use as choices for this field, *enumeration* choices, or a callable that returns such an iterable. This argument accepts the same formats as the `choices` argument to a model field. See the [model field reference documentation on choices](#) for more details. If the argument is a callable, it is evaluated each time the field’s form is initialized, in addition to during rendering. Defaults to an empty list.

DateField

```
class DateField(**kwargs)
```

- Default widget: *DateInput*
- Empty value: `None`
- Normalizes to: A Python `datetime.date` object.
- Validates that the given value is either a `datetime.date`, `datetime.datetime` or string formatted in a particular date format.
- Error message keys: `required`, `invalid`

Takes one optional argument:

input_formats

An iterable of formats used to attempt to convert a string to a valid `datetime.date` object.

If no `input_formats` argument is provided, the default input formats are taken from `DATE_INPUT_FORMATS` if `USE_L10N` is `False`, or from the active locale format `DATE_INPUT_FORMATS` key if localization is enabled. See also [format localization](#).

`DateTimeField`

```
class DateTimeField(**kwargs)
```

- Default widget: `DateTimeInput`
- Empty value: `None`
- Normalizes to: A Python `datetime.datetime` object.
- Validates that the given value is either a `datetime.datetime`, `datetime.date` or string formatted in a particular datetime format.
- Error message keys: `required`, `invalid`

Takes one optional argument:

input_formats

An iterable of formats used to attempt to convert a string to a valid `datetime.datetime` object, in addition to ISO 8601 formats.

The field always accepts strings in ISO 8601 formatted dates or similar recognized by `parse_datetime()`. Some examples are:

- `'2006-10-25 14:30:59'`
- `'2006-10-25T14:30:59'`
- `'2006-10-25 14:30'`
- `'2006-10-25T14:30'`
- `'2006-10-25T14:30Z'`
- `'2006-10-25T14:30+02:00'`
- `'2006-10-25'`

If no `input_formats` argument is provided, the default input formats are taken from `DATETIME_INPUT_FORMATS` and `DATE_INPUT_FORMATS` if `USE_L10N` is `False`, or from the active locale format `DATETIME_INPUT_FORMATS` and `DATE_INPUT_FORMATS` keys if localization is enabled. See also [format localization](#).

DecimalField

```
class DecimalField(**kwargs)
```

- Default widget: *NumberInput* when *Field.localize* is False, else *TextInput*.
- Empty value: None
- Normalizes to: A Python `decimal`.
- Validates that the given value is a decimal. Uses *MaxValueValidator* and *MinValueValidator* if *max_value* and *min_value* are provided. Uses *StepValueValidator* if *step_size* is provided. Leading and trailing whitespace is ignored.
- Error message keys: `required`, `invalid`, `max_value`, `min_value`, `max_digits`, `max_decimal_places`, `max_whole_digits`, `step_size`.

The *max_value* and *min_value* error messages may contain `%(limit_value)s`, which will be substituted by the appropriate limit. Similarly, the *max_digits*, *max_decimal_places* and *max_whole_digits* error messages may contain `%(max)s`.

Takes five optional arguments:

max_value

min_value

These control the range of values permitted in the field, and should be given as `decimal.Decimal` values.

max_digits

The maximum number of digits (those before the decimal point plus those after the decimal point, with leading zeros stripped) permitted in the value.

decimal_places

The maximum number of decimal places permitted.

step_size

Limit valid inputs to an integral multiple of *step_size*.

The *step_size* argument was added.

DurationField

```
class DurationField(**kwargs)
```

- Default widget: *TextInput*
- Empty value: `None`
- Normalizes to: A Python `timedelta`.
- Validates that the given value is a string which can be converted into a `timedelta`. The value must be between `datetime.timedelta.min` and `datetime.timedelta.max`.
- Error message keys: `required`, `invalid`, `overflow`.

Accepts any format understood by *parse_duration()*.

EmailField

```
class EmailField(**kwargs)
```

- Default widget: *EmailInput*
- Empty value: Whatever you've given as `empty_value`.
- Normalizes to: A string.
- Uses *EmailValidator* to validate that the given value is a valid email address, using a moderately complex regular expression.
- Error message keys: `required`, `invalid`

Has the optional arguments `max_length`, `min_length`, and `empty_value` which work just as they do for *CharField*. The `max_length` argument defaults to 320 (see RFC 3696#section-3).

The default value for `max_length` was changed to 320 characters.

FileField

```
class FileField(**kwargs)
```

- Default widget: *ClearableFileInput*
- Empty value: `None`
- Normalizes to: An `UploadedFile` object that wraps the file content and file name into a single object.
- Can validate that non-empty file data has been bound to the form.
- Error message keys: `required`, `invalid`, `missing`, `empty`, `max_length`

Has the optional arguments for validation: `max_length` and `allow_empty_file`. If provided, these ensure that the file name is at most the given length, and that validation will succeed even if the file content is empty.

To learn more about the `UploadedFile` object, see the [file uploads documentation](#).

When you use a `FileField` in a form, you must also remember to [bind the file data to the form](#).

The `max_length` error refers to the length of the filename. In the error message for that key, `%(max)d` will be replaced with the maximum filename length and `%(length)d` will be replaced with the current filename length.

`FilePathField`

```
class FilePathField(**kwargs)
```

- Default widget: `Select`
- Empty value: `''` (an empty string)
- Normalizes to: A string.
- Validates that the selected choice exists in the list of choices.
- Error message keys: `required`, `invalid_choice`

The field allows choosing from files inside a certain directory. It takes five extra arguments; only `path` is required:

`path`

The absolute path to the directory whose contents you want listed. This directory must exist.

`recursive`

If `False` (the default) only the direct contents of `path` will be offered as choices. If `True`, the directory will be descended into recursively and all descendants will be listed as choices.

`match`

A regular expression pattern; only files with names matching this expression will be allowed as choices.

`allow_files`

Optional. Either `True` or `False`. Default is `True`. Specifies whether files in the specified location should be included. Either this or `allow_folders` must be `True`.

`allow_folders`

Optional. Either `True` or `False`. Default is `False`. Specifies whether folders in the specified location should be included. Either this or `allow_files` must be `True`.

FloatField

```
class FloatField(**kwargs)
```

- Default widget: *NumberInput* when *Field.localize* is False, else *TextInput*.
- Empty value: None
- Normalizes to: A Python float.
- Validates that the given value is a float. Uses *MaxValueValidator* and *MinValueValidator* if *max_value* and *min_value* are provided. Uses *StepValueValidator* if *step_size* is provided. Leading and trailing whitespace is allowed, as in Python's `float()` function.
- Error message keys: `required`, `invalid`, `max_value`, `min_value`, `step_size`.

Takes three optional arguments:

max_value

min_value

These control the range of values permitted in the field.

step_size

Limit valid inputs to an integral multiple of *step_size*.

GenericIPAddressField

```
class GenericIPAddressField(**kwargs)
```

A field containing either an IPv4 or an IPv6 address.

- Default widget: *TextInput*
- Empty value: '' (an empty string)
- Normalizes to: A string. IPv6 addresses are normalized as described below.
- Validates that the given value is a valid IP address.
- Error message keys: `required`, `invalid`

The IPv6 address normalization follows [RFC 4291#section-2.2](#) section 2.2, including using the IPv4 format suggested in paragraph 3 of that section, like `::ffff:192.0.2.0`. For example, `2001:0::0:01` would be normalized to `2001::1`, and `::ffff:0a0a:0a0a` to `::ffff:10.10.10.10`. All characters are converted to lowercase.

Takes two optional arguments:

protocol

Limits valid inputs to the specified protocol. Accepted values are `both` (default), `IPv4` or `IPv6`. Matching is case insensitive.

`unpack_ipv4`

Unpacks IPv4 mapped addresses like `::ffff:192.0.2.1`. If this option is enabled that address would be unpacked to `192.0.2.1`. Default is disabled. Can only be used when `protocol` is set to `'both'`.

`ImageField`

```
class ImageField(**kwargs)
```

- Default widget: *`ClearableFileInput`*
- Empty value: `None`
- Normalizes to: An `UploadedFile` object that wraps the file content and file name into a single object.
- Validates that file data has been bound to the form. Also uses *`FileExtensionValidator`* to validate that the file extension is supported by Pillow.
- Error message keys: `required`, `invalid`, `missing`, `empty`, `invalid_image`

Using an `ImageField` requires that *Pillow* is installed with support for the image formats you use. If you encounter a `corrupt image` error when you upload an image, it usually means that Pillow doesn't understand its format. To fix this, install the appropriate library and reinstall Pillow.

When you use an `ImageField` on a form, you must also remember to *bind the file data to the form*.

After the field has been cleaned and validated, the `UploadedFile` object will have an additional `image` attribute containing the Pillow *Image* instance used to check if the file was a valid image. Pillow closes the underlying file descriptor after verifying an image, so while non-image data attributes, such as `format`, `height`, and `width`, are available, methods that access the underlying image data, such as `getdata()` or `getpixel()`, cannot be used without reopening the file. For example:

```
>>> from PIL import Image
>>> from django import forms
>>> from django.core.files.uploadedfile import SimpleUploadedFile
>>> class ImageForm(forms.Form):
...     img = forms.ImageField()
...
>>> file_data = {"img": SimpleUploadedFile("test.png", b"file data")}
>>> form = ImageForm({}, file_data)
# Pillow closes the underlying file descriptor.
>>> form.is_valid()
True
>>> image_field = form.cleaned_data["img"]
>>> image_field.image
<PIL.PngImagePlugin.PngImageFile image mode=RGBA size=191x287 at 0x7F5985045C18>
```

(continues on next page)

(continued from previous page)

```

>>> image_field.image.width
191
>>> image_field.image.height
287
>>> image_field.image.format
'PNG'
>>> image_field.image.getdata()
# Raises AttributeError: 'NoneType' object has no attribute 'seek'.
>>> image = Image.open(image_field)
>>> image.getdata()
<ImagingCore object at 0x7f5984f874b0>

```

Additionally, `UploadedFile.content_type` will be updated with the image's content type if Pillow can determine it, otherwise it will be set to `None`.

IntegerField

```
class IntegerField(**kwargs)
```

- Default widget: *NumberInput* when *Field.localize* is `False`, else *TextInput*.
- Empty value: `None`
- Normalizes to: A Python integer.
- Validates that the given value is an integer. Uses *MaxValueValidator* and *MinValueValidator* if *max_value* and *min_value* are provided. Uses *StepValueValidator* if *step_size* is provided. Leading and trailing whitespace is allowed, as in Python's `int()` function.
- Error message keys: `required`, `invalid`, `max_value`, `min_value`, `step_size`

The *max_value*, *min_value* and *step_size* error messages may contain `%(limit_value)s`, which will be substituted by the appropriate limit.

Takes three optional arguments for validation:

max_value

min_value

These control the range of values permitted in the field.

step_size

Limit valid inputs to an integral multiple of *step_size*.

JSONField

`class JSONField(encoder=None, decoder=None, **kwargs)`

A field which accepts JSON encoded data for a *JSONField*.

- Default widget: *Textarea*
- Empty value: `None`
- Normalizes to: A Python representation of the JSON value (usually as a dict, list, or `None`), depending on *JSONField.decoder*.
- Validates that the given value is a valid JSON.
- Error message keys: `required`, `invalid`

Takes two optional arguments:

encoder

A `json.JSONEncoder` subclass to serialize data types not supported by the standard JSON serializer (e.g. `datetime.datetime` or `UUID`). For example, you can use the *DjangoJSONEncoder* class.

Defaults to `json.JSONEncoder`.

decoder

A `json.JSONDecoder` subclass to deserialize the input. Your deserialization may need to account for the fact that you can't be certain of the input type. For example, you run the risk of returning a `datetime` that was actually a string that just happened to be in the same format chosen for `datetimes`.

The `decoder` can be used to validate the input. If `json.JSONDecodeError` is raised during the deserialization, a `ValidationError` will be raised.

Defaults to `json.JSONDecoder`.

Note: If you use a *ModelForm*, the `encoder` and `decoder` from *JSONField* will be used.

User friendly forms

JSONField is not particularly user friendly in most cases. However, it is a useful way to format data from a client-side widget for submission to the server.

MultipleChoiceField

```
class MultipleChoiceField(**kwargs)
```

- Default widget: *SelectMultiple*
- Empty value: [] (an empty list)
- Normalizes to: A list of strings.
- Validates that every value in the given list of values exists in the list of choices.
- Error message keys: `required`, `invalid_choice`, `invalid_list`

The `invalid_choice` error message may contain `%(value)s`, which will be replaced with the selected choice.

Takes one extra required argument, `choices`, as for *ChoiceField*.

NullBooleanField

```
class NullBooleanField(**kwargs)
```

- Default widget: *NullBooleanSelect*
- Empty value: `None`
- Normalizes to: A Python `True`, `False` or `None` value.
- Validates nothing (i.e., it never raises a `ValidationError`).

`NullBooleanField` may be used with widgets such as *Select* or *RadioSelect* by providing the widget `choices`:

```
NullBooleanField(
    widget=Select(
        choices=[
            ("", "Unknown"),
            (True, "Yes"),
            (False, "No"),
        ]
    )
)
```

RegexField

```
class RegexField(**kwargs)
```

- Default widget: *TextInput*
- Empty value: Whatever you've given as `empty_value`.
- Normalizes to: A string.
- Uses *RegexValidator* to validate that the given value matches a certain regular expression.
- Error message keys: `required`, `invalid`

Takes one required argument:

regex

A regular expression specified either as a string or a compiled regular expression object.

Also takes `max_length`, `min_length`, `strip`, and `empty_value` which work just as they do for *CharField*.

strip

Defaults to `False`. If enabled, stripping will be applied before the regex validation.

SlugField

```
class SlugField(**kwargs)
```

- Default widget: *TextInput*
- Empty value: Whatever you've given as *empty_value*.
- Normalizes to: A string.
- Uses *validate_slug* or *validate_unicode_slug* to validate that the given value contains only letters, numbers, underscores, and hyphens.
- Error messages: `required`, `invalid`

This field is intended for use in representing a model *SlugField* in forms.

Takes two optional parameters:

allow_unicode

A boolean instructing the field to accept Unicode letters in addition to ASCII letters. Defaults to `False`.

empty_value

The value to use to represent “empty”. Defaults to an empty string.

TimeField

```
class TimeField(**kwargs)
```

- Default widget: *TimeInput*
- Empty value: `None`
- Normalizes to: A Python `datetime.time` object.
- Validates that the given value is either a `datetime.time` or string formatted in a particular time format.
- Error message keys: `required`, `invalid`

Takes one optional argument:

input_formats

An iterable of formats used to attempt to convert a string to a valid `datetime.time` object.

If no `input_formats` argument is provided, the default input formats are taken from *TIME_INPUT_FORMATS* if *USE_L10N* is `False`, or from the active locale format `TIME_INPUT_FORMATS` key if localization is enabled. See also [format localization](#).

TypedChoiceField

```
class TypedChoiceField(**kwargs)
```

Just like a *ChoiceField*, except *TypedChoiceField* takes two extra arguments, *coerce* and *empty_value*.

- Default widget: *Select*
- Empty value: Whatever you've given as *empty_value*.
- Normalizes to: A value of the type provided by the *coerce* argument.
- Validates that the given value exists in the list of choices and can be coerced.
- Error message keys: `required`, `invalid_choice`

Takes extra arguments:

coerce

A function that takes one argument and returns a coerced value. Examples include the built-in `int`, `float`, `bool` and other types. Defaults to an identity function. Note that coercion happens after input validation, so it is possible to coerce to a value not present in `choices`.

empty_value

The value to use to represent “empty.” Defaults to the empty string; `None` is another common

choice here. Note that this value will not be coerced by the function given in the `coerce` argument, so choose it accordingly.

`TypedMultipleChoiceField`

```
class TypedMultipleChoiceField(**kwargs)
```

Just like a *MultipleChoiceField*, except *TypedMultipleChoiceField* takes two extra arguments, `coerce` and `empty_value`.

- Default widget: *SelectMultiple*
- Empty value: Whatever you've given as `empty_value`
- Normalizes to: A list of values of the type provided by the `coerce` argument.
- Validates that the given values exists in the list of choices and can be coerced.
- Error message keys: `required`, `invalid_choice`

The `invalid_choice` error message may contain `%(value)s`, which will be replaced with the selected choice.

Takes two extra arguments, `coerce` and `empty_value`, as for *TypedChoiceField*.

`URLField`

```
class URLField(**kwargs)
```

- Default widget: *URLInput*
- Empty value: Whatever you've given as `empty_value`.
- Normalizes to: A string.
- Uses *URLValidator* to validate that the given value is a valid URL.
- Error message keys: `required`, `invalid`

Has the optional arguments `max_length`, `min_length`, and `empty_value` which work just as they do for *CharField*.

UUIDField

```
class UUIDField(**kwargs)
```

- Default widget: *TextInput*
- Empty value: `None`
- Normalizes to: A `UUID` object.
- Error message keys: `required`, `invalid`

This field will accept any string format accepted as the `hex` argument to the `UUID` constructor.

Slightly complex built-in Field classes

ComboField

```
class ComboField(**kwargs)
```

- Default widget: *TextInput*
- Empty value: `''` (an empty string)
- Normalizes to: A string.
- Validates the given value against each of the fields specified as an argument to the `ComboField`.
- Error message keys: `required`, `invalid`

Takes one extra required argument:

fields

The list of fields that should be used to validate the field's value (in the order in which they are provided).

```
>>> from django.forms import ComboField
>>> f = ComboField(fields=[CharField(max_length=20), EmailField()])
>>> f.clean('test@example.com')
'test@example.com'
>>> f.clean('longemailaddress@example.com')
Traceback (most recent call last):
...
ValidationError: ['Ensure this value has at most 20 characters (it has 28).']
```

MultiValueField

```
class MultiValueField(fields=(), **kwargs)
```

- Default widget: *TextInput*
- Empty value: '' (an empty string)
- Normalizes to: the type returned by the `compress` method of the subclass.
- Validates the given value against each of the fields specified as an argument to the `MultiValueField`.
- Error message keys: `required`, `invalid`, `incomplete`

Aggregates the logic of multiple fields that together produce a single value.

This field is abstract and must be subclassed. In contrast with the single-value fields, subclasses of *MultiValueField* must not implement `clean()` but instead - implement `compress()`.

Takes one extra required argument:

`fields`

A tuple of fields whose values are cleaned and subsequently combined into a single value. Each value of the field is cleaned by the corresponding field in `fields` –the first value is cleaned by the first field, the second value is cleaned by the second field, etc. Once all fields are cleaned, the list of clean values is combined into a single value by `compress()`.

Also takes some optional arguments:

`require_all_fields`

Defaults to `True`, in which case a `required` validation error will be raised if no value is supplied for any field.

When set to `False`, the *Field.required* attribute can be set to `False` for individual fields to make them optional. If no value is supplied for a required field, an `incomplete` validation error will be raised.

A default `incomplete` error message can be defined on the *MultiValueField* subclass, or different messages can be defined on each individual field. For example:

```
from django.core.validators import RegexValidator

class PhoneField(MultiValueField):
    def __init__(self, **kwargs):
        # Define one message for all fields.
        error_messages = {
            "incomplete": "Enter a country calling code and a phone number.",
```

(continues on next page)

(continued from previous page)

```

}
# Or define a different message for each field.
fields = (
    CharField(
        error_messages={"incomplete": "Enter a country calling code."},
        validators=[
            RegexValidator(r"^[0-9]+$", "Enter a valid country calling code."),
        ],
    ),
    CharField(
        error_messages={"incomplete": "Enter a phone number."},
        validators=[RegexValidator(r"^[0-9]+$", "Enter a valid phone number.")],
    ),
    CharField(
        validators=[RegexValidator(r"^[0-9]+$", "Enter a valid extension.")],
        required=False,
    ),
)
super().__init__(
    error_messages=error_messages,
    fields=fields,
    require_all_fields=False,
    **kwargs
)

```

widget

Must be a subclass of `django.forms.MultiWidget`. Default value is `TextInput`, which probably is not very useful in this case.

compress(data_list)

Takes a list of valid values and returns a “compressed” version of those values—in a single value. For example, `SplitDateTimeField` is a subclass which combines a time field and a date field into a datetime object.

This method must be implemented in the subclasses.

SplitDateTimeField

```
class SplitDateTimeField(**kwargs)
```

- Default widget: *SplitDateTimeWidget*
- Empty value: `None`
- Normalizes to: A Python `datetime.datetime` object.
- Validates that the given value is a `datetime.datetime` or string formatted in a particular datetime format.
- Error message keys: `required`, `invalid`, `invalid_date`, `invalid_time`

Takes two optional arguments:

`input_date_formats`

A list of formats used to attempt to convert a string to a valid `datetime.date` object.

If no `input_date_formats` argument is provided, the default input formats for *DateField* are used.

`input_time_formats`

A list of formats used to attempt to convert a string to a valid `datetime.time` object.

If no `input_time_formats` argument is provided, the default input formats for *TimeField* are used.

Fields which handle relationships

Two fields are available for representing relationships between models: *ModelChoiceField* and *ModelMultipleChoiceField*. Both of these fields require a single `queryset` parameter that is used to create the choices for the field. Upon form validation, these fields will place either one model object (in the case of *ModelChoiceField*) or multiple model objects (in the case of *ModelMultipleChoiceField*) into the `cleaned_data` dictionary of the form.

For more complex uses, you can specify `queryset=None` when declaring the form field and then populate the `queryset` in the form's `__init__()` method:

```
class FooMultipleChoiceForm(forms.Form):
    foo_select = forms.ModelMultipleChoiceField(queryset=None)

    def __init__(self, *args, **kwargs):
        super().__init__(*args, **kwargs)
        self.fields["foo_select"].queryset = ...
```

Both *ModelChoiceField* and *ModelMultipleChoiceField* have an `iterator` attribute which specifies the class used to iterate over the `queryset` when generating choices. See [Iterating relationship choices](#) for details.

ModelChoiceField

```
class ModelChoiceField(**kwargs)
```

- Default widget: *Select*
- Empty value: `None`
- Normalizes to: A model instance.
- Validates that the given id exists in the queryset.
- Error message keys: `required`, `invalid_choice`

The `invalid_choice` error message may contain `%(value)s`, which will be replaced with the selected choice.

Allows the selection of a single model object, suitable for representing a foreign key. Note that the default widget for `ModelChoiceField` becomes impractical when the number of entries increases. You should avoid using it for more than 100 items.

A single argument is required:

queryset

A `QuerySet` of model objects from which the choices for the field are derived and which is used to validate the user's selection. It's evaluated when the form is rendered.

`ModelChoiceField` also takes several optional arguments:

empty_label

By default the `<select>` widget used by `ModelChoiceField` will have an empty choice at the top of the list. You can change the text of this label (which is `"-----"` by default) with the `empty_label` attribute, or you can disable the empty label entirely by setting `empty_label` to `None`:

```
# A custom empty label
field1 = forms.ModelChoiceField(queryset=..., empty_label="(Nothing)")

# No empty label
field2 = forms.ModelChoiceField(queryset=..., empty_label=None)
```

Note that no empty choice is created (regardless of the value of `empty_label`) if a `ModelChoiceField` is required and has a default initial value, or a widget is set to *RadioSelect* and the *blank* argument is `False`.

to_field_name

This optional argument is used to specify the field to use as the value of the choices in the field's widget. Be sure it's a unique field for the model, otherwise the selected value could match more

than one object. By default it is set to `None`, in which case the primary key of each object will be used. For example:

```
# No custom to_field_name
field1 = forms.ModelChoiceField(queryset=...)
```

would yield:

```
<select id="id_field1" name="field1">
<option value="obj1.pk">Object1</option>
<option value="obj2.pk">Object2</option>
...
</select>
```

and:

```
# to_field_name provided
field2 = forms.ModelChoiceField(queryset=..., to_field_name="name")
```

would yield:

```
<select id="id_field2" name="field2">
<option value="obj1.name">Object1</option>
<option value="obj2.name">Object2</option>
...
</select>
```

blank

When using the *RadioSelect* widget, this optional boolean argument determines whether an empty choice is created. By default, `blank` is `False`, in which case no empty choice is created.

`ModelChoiceField` also has the attribute:

iterator

The iterator class used to generate field choices from `queryset`. By default, *ModelChoiceIterator*.

The `__str__()` method of the model will be called to generate string representations of the objects for use in the field's choices. To provide customized representations, subclass `ModelChoiceField` and override `label_from_instance`. This method will receive a model object and should return a string suitable for representing it. For example:

```
from django.forms import ModelChoiceField

class MyModelChoiceField(ModelChoiceField):
```

(continues on next page)

(continued from previous page)

```
def label_from_instance(self, obj):
    return "My Object #%i" % obj.id
```

ModelMultipleChoiceField

```
class ModelMultipleChoiceField(**kwargs)
```

- Default widget: *SelectMultiple*
- Empty value: An empty `QuerySet` (`self.queryset.none()`)
- Normalizes to: A `QuerySet` of model instances.
- Validates that every id in the given list of values exists in the `queryset`.
- Error message keys: `required`, `invalid_list`, `invalid_choice`, `invalid_pk_value`

The `invalid_choice` message may contain `%(value)s` and the `invalid_pk_value` message may contain `%(pk)s`, which will be substituted by the appropriate values.

Allows the selection of one or more model objects, suitable for representing a many-to-many relation. As with *ModelChoiceField*, you can use `label_from_instance` to customize the object representations.

A single argument is required:

queryset

Same as *ModelChoiceField.queryset*.

Takes one optional argument:

to_field_name

Same as *ModelChoiceField.to_field_name*.

`ModelMultipleChoiceField` also has the attribute:

iterator

Same as *ModelChoiceField.iterator*.

Iterating relationship choices

By default, *ModelChoiceField* and *ModelMultipleChoiceField* use *ModelChoiceIterator* to generate their field choices.

When iterated, *ModelChoiceIterator* yields 2-tuple choices containing *ModelChoiceIteratorValue* instances as the first value element in each choice. *ModelChoiceIteratorValue* wraps the choice value while maintaining a reference to the source model instance that can be used in custom widget implementations, for example, to add `data-* attributes` to `<option>` elements.

For example, consider the following models:

```
from django.db import models

class Topping(models.Model):
    name = models.CharField(max_length=100)
    price = models.DecimalField(decimal_places=2, max_digits=6)

    def __str__(self):
        return self.name

class Pizza(models.Model):
    topping = models.ForeignKey(Topping, on_delete=models.CASCADE)
```

You can use a `Select` widget subclass to include the value of `Topping.price` as the HTML attribute `data-price` for each `<option>` element:

```
from django import forms

class ToppingSelect(forms.Select):
    def create_option(
        self, name, value, label, selected, index, subindex=None, attrs=None
    ):
        option = super().create_option(
            name, value, label, selected, index, subindex, attrs
        )
        if value:
            option["attrs"]["data-price"] = value.instance.price
        return option

class PizzaForm(forms.ModelForm):
    class Meta:
        model = Pizza
        fields = ["topping"]
        widgets = {"topping": ToppingSelect}
```

This will render the `Pizza.topping` select as:

```
<select id="id_topping" name="topping" required>
<option value="" selected>-----</option>
<option value="1" data-price="1.50">mushrooms</option>
```

(continues on next page)

(continued from previous page)

```
<option value="2" data-price="1.25">onions</option>
<option value="3" data-price="1.75">peppers</option>
<option value="4" data-price="2.00">pineapple</option>
</select>
```

For more advanced usage you may subclass `ModelChoiceIterator` in order to customize the yielded 2-tuple choices.

ModelChoiceIterator

```
class ModelChoiceIterator(field)
```

The default class assigned to the `iterator` attribute of `ModelChoiceField` and `ModelMultipleChoiceField`. An iterable that yields 2-tuple choices from the queryset.

A single argument is required:

field

The instance of `ModelChoiceField` or `ModelMultipleChoiceField` to iterate and yield choices.

`ModelChoiceIterator` has the following method:

`__iter__()`

Yields 2-tuple choices, in the (value, label) format used by `ChoiceField.choices`. The first value element is a `ModelChoiceIteratorValue` instance.

ModelChoiceIteratorValue

```
class ModelChoiceIteratorValue(value, instance)
```

Two arguments are required:

value

The value of the choice. This value is used to render the `value` attribute of an HTML `<option>` element.

instance

The model instance from the queryset. The instance can be accessed in custom `ChoiceWidget.create_option()` implementations to adjust the rendered HTML.

`ModelChoiceIteratorValue` has the following method:

`__str__()`

Return `value` as a string to be rendered in HTML.

Creating custom fields

If the built-in `Field` classes don't meet your needs, you can create custom `Field` classes. To do this, create a subclass of `django.forms.Field`. Its only requirements are that it implement a `clean()` method and that its `__init__()` method accept the core arguments mentioned above (`required`, `label`, `initial`, `widget`, `help_text`).

You can also customize how a field will be accessed by overriding `get_bound_field()`.

6.12.3 Model Form Functions

Model Form API reference. For introductory material about model forms, see the [Creating forms from models](#) topic guide.

`modelform_factory`

```
modelform_factory(model, form=ModelForm, fields=None, exclude=None, formfield_callback=None,
                  widgets=None, localized_fields=None, labels=None, help_texts=None,
                  error_messages=None, field_classes=None)
```

Returns a *ModelForm* class for the given `model`. You can optionally pass a `form` argument to use as a starting point for constructing the `ModelForm`.

`fields` is an optional list of field names. If provided, only the named fields will be included in the returned fields.

`exclude` is an optional list of field names. If provided, the named fields will be excluded from the returned fields, even if they are listed in the `fields` argument.

`formfield_callback` is a callable that takes a model field and returns a form field.

`widgets` is a dictionary of model field names mapped to a widget.

`localized_fields` is a list of names of fields which should be localized.

`labels` is a dictionary of model field names mapped to a label.

`help_texts` is a dictionary of model field names mapped to a help text.

`error_messages` is a dictionary of model field names mapped to a dictionary of error messages.

`field_classes` is a dictionary of model field names mapped to a form field class.

See [ModelForm factory function](#) for example usage.

You must provide the list of fields explicitly, either via keyword arguments `fields` or `exclude`, or the corresponding attributes on the form's inner `Meta` class. See [Selecting the fields to use](#) for more information. Omitting any definition of the fields to use will result in an *ImproperlyConfigured* exception.

`modelformset_factory`

```
modelformset_factory(model, form=ModelForm, formfield_callback=None,
                     formset=BaseModelFormSet, extra=1, can_delete=False, can_order=False,
                     max_num=None, fields=None, exclude=None, widgets=None,
                     validate_max=False, localized_fields=None, labels=None, help_texts=None,
                     error_messages=None, min_num=None, validate_min=False, field_classes=None,
                     absolute_max=None, can_delete_extra=True, renderer=None, edit_only=False)
```

Returns a `FormSet` class for the given `model` class.

Arguments `model`, `form`, `fields`, `exclude`, `formfield_callback`, `widgets`, `localized_fields`, `labels`, `help_texts`, `error_messages`, and `field_classes` are all passed through to `modelform_factory()`.

Arguments `formset`, `extra`, `can_delete`, `can_order`, `max_num`, `validate_max`, `min_num`, `validate_min`, `absolute_max`, `can_delete_extra`, and `renderer` are passed through to `formset_factory()`. See [formsets](#) for details.

The `edit_only` argument allows [preventing new objects creation](#).

See [Model formsets](#) for example usage.

The `edit_only` argument was added.

`inlineformset_factory`

```
inlineformset_factory(parent_model, model, form=ModelForm, formset=BaseInlineFormSet,
                     fk_name=None, fields=None, exclude=None, extra=3, can_order=False,
                     can_delete=True, max_num=None, formfield_callback=None, widgets=None,
                     validate_max=False, localized_fields=None, labels=None, help_texts=None,
                     error_messages=None, min_num=None, validate_min=False,
                     field_classes=None, absolute_max=None, can_delete_extra=True,
                     renderer=None, edit_only=False)
```

Returns an `InlineFormSet` using `modelformset_factory()` with defaults of `formset=BaseInlineFormSet`, `can_delete=True`, and `extra=3`.

If your model has more than one `ForeignKey` to the `parent_model`, you must specify a `fk_name`.

See [Inline formsets](#) for example usage.

The `edit_only` argument was added.

6.12.4 Formset Functions

Formset API reference. For introductory material about formsets, see the [Formsets](#) topic guide.

`formset_factory`

```
formset_factory(form, formset=BaseFormSet, extra=1, can_order=False, can_delete=False,
                 max_num=None, validate_max=False, min_num=None, validate_min=False,
                 absolute_max=None, can_delete_extra=True, renderer=None)
```

Returns a `FormSet` class for the given `form` class.

See [formsets](#) for example usage.

6.12.5 The form rendering API

Django's form widgets are rendered using Django's [template engines system](#).

The form rendering process can be customized at several levels:

- Widgets can specify custom template names.
- Forms and widgets can specify custom renderer classes.
- A widget's template can be overridden by a project. (Reusable applications typically shouldn't override built-in templates because they might conflict with a project's custom templates.)

The low-level render API

The rendering of form templates is controlled by a customizable renderer class. A custom renderer can be specified by updating the `FORM_RENDERER` setting. It defaults to `'django.forms.renderers.DjangoTemplates'`.

By specifying a custom form renderer and overriding `form_template_name` you can adjust the default form markup across your project from a single place.

You can also provide a custom renderer per-form or per-widget by setting the `Form.default_renderer` attribute or by using the `renderer` argument of `Form.render()`, or `Widget.render()`.

Matching points apply to formset rendering. See [Using a formset in views and templates](#) for discussion.

Use one of the [built-in template form renderers](#) or implement your own. Custom renderers must implement a `render(template_name, context, request=None)` method. It should return a rendered templates (as a string) or raise `TemplateDoesNotExist`.

```
class BaseRenderer
```

The base class for the built-in form renderers.

form_template_name

The default name of the template to use to render a form.

Defaults to "django/forms/default.html", which is a proxy for "django/forms/table.html".

Deprecated since version 4.1.

The "django/forms/default.html" template is deprecated and will be removed in Django 5.0.

The default will become "django/forms/div.html" at that time.

formset_template_name

The default name of the template to use to render a formset.

Defaults to "django/forms/formsets/default.html", which is a proxy for "django/forms/formsets/table.html".

Deprecated since version 4.1.

The "django/forms/formset/default.html" template is deprecated and will be removed in Django 5.0. The default will become "django/forms/formset/div.html" template.

get_template(template_name)

Subclasses must implement this method with the appropriate template finding logic.

render(template_name, context, request=None)

Renders the given template, or raises *TemplateDoesNotExist*.

Built-in-template form renderers

DjangoTemplates

class DjangoTemplates

This renderer uses a standalone *DjangoTemplates* engine (unconnected to what you might have configured in the *TEMPLATES* setting). It loads templates first from the built-in form templates directory in `django/forms/templates` and then from the installed apps' templates directories using the *app_directories* loader.

If you want to render templates with customizations from your *TEMPLATES* setting, such as context processors for example, use the *TemplatesSetting* renderer.

class DjangoDivFormRenderer

Subclass of *DjangoTemplates* that specifies *form_template_name* and *formset_template_name* as "django/forms/div.html" and "django/forms/formset/div.html" respectively.

This is a transitional renderer for opt-in to the new <div> based templates, which are the default from Django 5.0.

Apply this via the *FORM_RENDERER* setting:

```
FORM_RENDERER = "django.forms.renderers.DjangoDivFormRenderer"
```

Once the `<div>` templates are the default, this transitional renderer will be deprecated, for removal in Django 6.0. The `FORM_RENDERER` declaration can be removed at that time.

Jinja2

```
class Jinja2
```

This renderer is the same as the *DjangoTemplates* renderer except that it uses a *Jinja2* backend. Templates for the built-in widgets are located in `django/forms/jinja2` and installed apps can provide templates in a `jinja2` directory.

To use this backend, all the forms and widgets in your project and its third-party apps must have Jinja2 templates. Unless you provide your own Jinja2 templates for widgets that don't have any, you can't use this renderer. For example, *django.contrib.admin* doesn't include Jinja2 templates for its widgets due to their usage of Django template tags.

```
class Jinja2DivFormRenderer
```

A transitional renderer as per *DjangoDivFormRenderer* above, but subclassing *Jinja2* for use with the Jinja2 backend.

Apply this via the *FORM_RENDERER* setting:

```
FORM_RENDERER = "django.forms.renderers.Jinja2DivFormRenderer"
```

TemplatesSetting

```
class TemplatesSetting
```

This renderer gives you complete control of how form and widget templates are sourced. It uses *get_template()* to find templates based on what's configured in the *TEMPLATES* setting.

Using this renderer along with the built-in templates requires either:

- `'django.forms'` in *INSTALLED_APPS* and at least one engine with *APP_DIRS=True*.
- Adding the built-in templates directory in *DIRS* of one of your template engines. To generate that path:

```
import django

django.__path__[0] + "/forms/templates" # or '/forms/jinja2'
```

Using this renderer requires you to make sure the form templates your project needs can be located.

Context available in formset templates

Formset templates receive a context from `BaseFormSet.get_context()`. By default, formsets receive a dictionary with the following values:

- `formset`: The formset instance.

Context available in form templates

Form templates receive a context from `Form.get_context()`. By default, forms receive a dictionary with the following values:

- `form`: The bound form.
- `fields`: All bound fields, except the hidden fields.
- `hidden_fields`: All hidden bound fields.
- `errors`: All non field related or hidden field related form errors.

Context available in widget templates

Widget templates receive a context from `Widget.get_context()`. By default, widgets receive a single value in the context, `widget`. This is a dictionary that contains values like:

- `name`
- `value`
- `attrs`
- `is_hidden`
- `template_name`

Some widgets add further information to the context. For instance, all widgets that subclass `Input` defines `widget['type']` and `MultiWidget` defines `widget['subwidgets']` for looping purposes.

Overriding built-in formset templates

`BaseFormSet.template_name`

To override formset templates, you must use the `TemplatesSetting` renderer. Then overriding formset templates works the same as overriding any other template in your project.

Overriding built-in form templates

Form.template_name

To override form templates, you must use the *TemplatesSetting* renderer. Then overriding form templates works [the same as](#) overriding any other template in your project.

Overriding built-in widget templates

Each widget has a `template_name` attribute with a value such as `input.html`. Built-in widget templates are stored in the `django/forms/widgets` path. You can provide a custom template for `input.html` by defining `django/forms/widgets/input.html`, for example. See [Built-in widgets](#) for the name of each widget's template.

To override widget templates, you must use the *TemplatesSetting* renderer. Then overriding widget templates works [the same as](#) overriding any other template in your project.

6.12.6 Widgets

A widget is Django's representation of an HTML input element. The widget handles the rendering of the HTML, and the extraction of data from a GET/POST dictionary that corresponds to the widget.

The HTML generated by the built-in widgets uses HTML5 syntax, targeting `<!DOCTYPE html>`. For example, it uses boolean attributes such as `checked` rather than the XHTML style of `checked= 'checked'`.

Tip: Widgets should not be confused with the [form fields](#). Form fields deal with the logic of input validation and are used directly in templates. Widgets deal with rendering of HTML form input elements on the web page and extraction of raw submitted data. However, widgets do need to be [assigned](#) to form fields.

Specifying widgets

Whenever you specify a field on a form, Django will use a default widget that is appropriate to the type of data that is to be displayed. To find which widget is used on which field, see the documentation about [Built-in Field classes](#).

However, if you want to use a different widget for a field, you can use the *widget* argument on the field definition. For example:

```
from django import forms

class CommentForm(forms.Form):
```

(continues on next page)

(continued from previous page)

```
name = forms.CharField()
url = forms.URLField()
comment = forms.CharField(widget=forms.Textarea)
```

This would specify a form with a comment that uses a larger *Textarea* widget, rather than the default *TextInput* widget.

Setting arguments for widgets

Many widgets have optional extra arguments; they can be set when defining the widget on the field. In the following example, the *years* attribute is set for a *SelectDateWidget*:

```
from django import forms

BIRTH_YEAR_CHOICES = ["1980", "1981", "1982"]
FAVORITE_COLORS_CHOICES = [
    ("blue", "Blue"),
    ("green", "Green"),
    ("black", "Black"),
]

class SimpleForm(forms.Form):
    birth_year = forms.DateField(
        widget=forms.SelectDateWidget(years=BIRTH_YEAR_CHOICES)
    )
    favorite_colors = forms.MultipleChoiceField(
        required=False,
        widget=forms.CheckboxSelectMultiple,
        choices=FAVORITE_COLORS_CHOICES,
    )
```

See the [Built-in widgets](#) for more information about which widgets are available and which arguments they accept.

Widgets inheriting from the `Select` widget

Widgets inheriting from the `Select` widget deal with choices. They present the user with a list of options to choose from. The different widgets present this choice differently; the `Select` widget itself uses a `<select>` HTML list representation, while `RadioSelect` uses radio buttons.

`Select` widgets are used by default on `ChoiceField` fields. The choices displayed on the widget are inherited from the `ChoiceField` and changing `ChoiceField.choices` will update `Select.choices`. For example:

```
>>> from django import forms
>>> CHOICES = [("1", "First"), ("2", "Second")]
>>> choice_field = forms.ChoiceField(widget=forms.RadioSelect, choices=CHOICES)
>>> choice_field.choices
[('1', 'First'), ('2', 'Second')]
>>> choice_field.widget.choices
[('1', 'First'), ('2', 'Second')]
>>> choice_field.widget.choices = []
>>> choice_field.choices = [("1", "First and only")]
>>> choice_field.widget.choices
[('1', 'First and only')]
```

Widgets which offer a `choices` attribute can however be used with fields which are not based on choice – such as a `CharField` – but it is recommended to use a `ChoiceField`-based field when the choices are inherent to the model and not just the representational widget.

Customizing widget instances

When Django renders a widget as HTML, it only renders very minimal markup – Django doesn't add class names, or any other widget-specific attributes. This means, for example, that all `TextInput` widgets will appear the same on your web pages.

There are two ways to customize widgets: [per widget instance](#) and [per widget class](#).

Styling widget instances

If you want to make one widget instance look different from another, you will need to specify additional attributes at the time when the widget object is instantiated and assigned to a form field (and perhaps add some rules to your CSS files).

For example, take the following form:

```
from django import forms
```

(continues on next page)

(continued from previous page)

```
class CommentForm(forms.Form):
    name = forms.CharField()
    url = forms.URLField()
    comment = forms.CharField()
```

This form will include three default *TextInput* widgets, with default rendering –no CSS class, no extra attributes. This means that the input boxes provided for each widget will be rendered exactly the same:

```
>>> f = CommentForm(auto_id=False)
>>> f.as_table()
<tr><th>Name:</th><td><input type="text" name="name" required></td></tr>
<tr><th>Url:</th><td><input type="url" name="url" required></td></tr>
<tr><th>Comment:</th><td><input type="text" name="comment" required></td></tr>
```

On a real web page, you probably don't want every widget to look the same. You might want a larger input element for the comment, and you might want the 'name' widget to have some special CSS class. It is also possible to specify the 'type' attribute to take advantage of the new HTML5 input types. To do this, you use the *Widget.attrs* argument when creating the widget:

```
class CommentForm(forms.Form):
    name = forms.CharField(widget=forms.TextInput(attrs={"class": "special"}))
    url = forms.URLField()
    comment = forms.CharField(widget=forms.TextInput(attrs={"size": "40"}))
```

You can also modify a widget in the form definition:

```
class CommentForm(forms.Form):
    name = forms.CharField()
    url = forms.URLField()
    comment = forms.CharField()

    name.widget.attrs.update({"class": "special"})
    comment.widget.attrs.update(size="40")
```

Or if the field isn't declared directly on the form (such as model form fields), you can use the *Form.fields* attribute:

```
class CommentForm(forms.ModelForm):
    def __init__(self, *args, **kwargs):
        super().__init__(*args, **kwargs)
        self.fields["name"].widget.attrs.update({"class": "special"})
        self.fields["comment"].widget.attrs.update(size="40")
```

Django will then include the extra attributes in the rendered output:

```
>>> f = CommentForm(auto_id=False)
>>> f.as_table()
<tr><th>Name:</th><td><input type="text" name="name" class="special" required></td></tr>
<tr><th>Url:</th><td><input type="url" name="url" required></td></tr>
<tr><th>Comment:</th><td><input type="text" name="comment" size="40" required></td></tr>
```

You can also set the HTML id using *attrs*. See *BoundField.id_for_label* for an example.

Styling widget classes

With widgets, it is possible to add assets (css and javascript) and more deeply customize their appearance and behavior.

In a nutshell, you will need to subclass the widget and either define a “Media” inner class or create a “media” property.

These methods involve somewhat advanced Python programming and are described in detail in the [Form Assets](#) topic guide.

Base widget classes

Base widget classes *Widget* and *MultiWidget* are subclassed by all the [built-in widgets](#) and may serve as a foundation for custom widgets.

Widget

```
class Widget(attrs=None)
```

This abstract class cannot be rendered, but provides the basic attribute *attrs*. You may also implement or override the *render()* method on custom widgets.

attrs

A dictionary containing HTML attributes to be set on the rendered widget.

```
>>> from django import forms
>>> name = forms.TextInput(attrs={"size": 10, "title": "Your name"})
>>> name.render("name", "A name")
'<input title="Your name" type="text" name="name" value="A name" size="10">'
```

If you assign a value of `True` or `False` to an attribute, it will be rendered as an HTML5 boolean attribute:

```
>>> name = forms.TextInput(attrs={"required": True})
>>> name.render("name", "A name")
'<input name="name" type="text" value="A name" required>'
>>>
>>> name = forms.TextInput(attrs={"required": False})
>>> name.render("name", "A name")
'<input name="name" type="text" value="A name">'
```

supports_microseconds

An attribute that defaults to `True`. If set to `False`, the microseconds part of `datetime` and `time` values will be set to 0.

format_value(value)

Cleans and returns a value for use in the widget template. `value` isn't guaranteed to be valid input, therefore subclass implementations should program defensively.

get_context(name, value, attrs)

Returns a dictionary of values to use when rendering the widget template. By default, the dictionary contains a single key, `'widget'`, which is a dictionary representation of the widget containing the following keys:

- `'name'`: The name of the field from the `name` argument.
- `'is_hidden'`: A boolean indicating whether or not this widget is hidden.
- `'required'`: A boolean indicating whether or not the field for this widget is required.
- `'value'`: The value as returned by `format_value()`.
- `'attrs'`: HTML attributes to be set on the rendered widget. The combination of the `attrs` attribute and the `attrs` argument.
- `'template_name'`: The value of `self.template_name`.

Widget subclasses can provide custom context values by overriding this method.

id_for_label(id_)

Returns the HTML ID attribute of this widget for use by a `<label>`, given the ID of the field. Returns an empty string if an ID isn't available.

This hook is necessary because some widgets have multiple HTML elements and, thus, multiple IDs. In that case, this method should return an ID value that corresponds to the first ID in the widget's tags.

render(name, value, attrs=None, renderer=None)

Renders a widget to HTML using the given renderer. If `renderer` is `None`, the renderer from the `FORM_RENDERER` setting is used.

`value_from_datadict(data, files, name)`

Given a dictionary of data and this widget's name, returns the value of this widget. `files` may contain data coming from `request.FILES`. Returns `None` if a value wasn't provided. Note also that `value_from_datadict` may be called more than once during handling of form data, so if you customize it and add expensive processing, you should implement some caching mechanism yourself.

`value_omitted_from_data(data, files, name)`

Given `data` and `files` dictionaries and this widget's name, returns whether or not there's data or files for the widget.

The method's result affects whether or not a field in a model form [falls back to its default](#).

Special cases are `CheckboxInput`, `CheckboxSelectMultiple`, and `SelectMultiple`, which always return `False` because an unchecked checkbox and unselected `<select multiple>` don't appear in the data of an HTML form submission, so it's unknown whether or not the user submitted a value.

`use_fieldset`

An attribute to identify if the widget should be grouped in a `<fieldset>` with a `<legend>` when rendered. Defaults to `False` but is `True` when the widget contains multiple `<input>` tags such as `CheckboxSelectMultiple`, `RadioSelect`, `MultiWidget`, `SplitDateTimeWidget`, and `SelectDateWidget`.

`use_required_attribute(initial)`

Given a form field's `initial` value, returns whether or not the widget can be rendered with the `required` HTML attribute. Forms use this method along with `Field.required` and `Form.use_required_attribute` to determine whether or not to display the `required` attribute for each field.

By default, returns `False` for hidden widgets and `True` otherwise. Special cases are `FileInput` and `ClearableFileInput`, which return `False` when `initial` is set, and `CheckboxSelectMultiple`, which always returns `False` because browser validation would require all checkboxes to be checked instead of at least one.

Override this method in custom widgets that aren't compatible with browser validation. For example, a WYSIWYG text editor widget backed by a hidden `textarea` element may want to always return `False` to avoid browser validation on the hidden field.

MultiWidget

class MultiWidget(widgets, attrs=None)

A widget that is composed of multiple widgets. *MultiWidget* works hand in hand with the *MultiValueField*.

MultiWidget has one required argument:

widgets

An iterable containing the widgets needed. For example:

```
>>> from django.forms import MultiWidget, TextInput
>>> widget = MultiWidget(widgets=[TextInput, TextInput])
>>> widget.render("name", ["john", "paul"])
'<input type="text" name="name_0" value="john"><input type="text" name="name_1" value=
↳ "paul">'
```

You may provide a dictionary in order to specify custom suffixes for the `name` attribute on each subwidget. In this case, for each `(key, widget)` pair, the key will be appended to the `name` of the widget in order to generate the attribute value. You may provide the empty string (`' '`) for a single key, in order to suppress the suffix for one widget. For example:

```
>>> widget = MultiWidget(widgets={"": TextInput, "last": TextInput})
>>> widget.render("name", ["john", "paul"])
'<input type="text" name="name" value="john"><input type="text" name="name_last" value=
↳ "paul">'
```

And one required method:

decompress(value)

This method takes a single “compressed” value from the field and returns a list of “decompressed” values. The input value can be assumed valid, but not necessarily non-empty.

This method must be implemented by the subclass, and since the value may be empty, the implementation must be defensive.

The rationale behind “decompression” is that it is necessary to “split” the combined value of the form field into the values for each widget.

An example of this is how *SplitDateTimeWidget* turns a `datetime` value into a list with date and time split into two separate values:

```
from django.forms import MultiWidget

class SplitDateTimeWidget(MultiWidget):
```

(continues on next page)

(continued from previous page)

```
# ...

def decompress(self, value):
    if value:
        return [value.date(), value.time()]
    return [None, None]
```

Tip: Note that *MultiValueField* has a complementary method *compress()* with the opposite responsibility - to combine cleaned values of all member fields into one.

It provides some custom context:

`get_context(name, value, attrs)`

In addition to the 'widget' key described in *Widget.get_context()*, *MultiWidget* adds a `widget['subwidgets']` key.

These can be looped over in the widget template:

```
{% for subwidget in widget.subwidgets %}
    {% include subwidget.template_name with widget=subwidget %}
{% endfor %}
```

Here's an example widget which subclasses *MultiWidget* to display a date with the day, month, and year in different select boxes. This widget is intended to be used with a *DateField* rather than a *MultiValueField*, thus we have implemented *value_from_datadict()*:

```
from datetime import date
from django import forms

class DateSelectorWidget(forms.MultiWidget):
    def __init__(self, attrs=None):
        days = [(day, day) for day in range(1, 32)]
        months = [(month, month) for month in range(1, 13)]
        years = [(year, year) for year in [2018, 2019, 2020]]
        widgets = [
            forms.Select(attrs=attrs, choices=days),
            forms.Select(attrs=attrs, choices=months),
            forms.Select(attrs=attrs, choices=years),
        ]
        super().__init__(widgets, attrs)
```

(continues on next page)

(continued from previous page)

```

def decompress(self, value):
    if isinstance(value, date):
        return [value.day, value.month, value.year]
    elif isinstance(value, str):
        year, month, day = value.split("-")
        return [day, month, year]
    return [None, None, None]

def value_from_datadict(self, data, files, name):
    day, month, year = super().value_from_datadict(data, files, name)
    # DateField expects a single string that it can parse into a date.
    return "{}-{}-{}".format(year, month, day)

```

The constructor creates several *Select* widgets in a list. The `super()` method uses this list to set up the widget.

The required method `decompress()` breaks up a `datetime.date` value into the day, month, and year values corresponding to each widget. If an invalid date was selected, such as the non-existent 30th February, the *DateField* passes this method a string instead, so that needs parsing. The final `return` handles when `value` is `None`, meaning we don't have any defaults for our subwidgets.

The default implementation of `value_from_datadict()` returns a list of values corresponding to each *Widget*. This is appropriate when using a *MultiWidget* with a *MultiValueField*. But since we want to use this widget with a *DateField*, which takes a single value, we have overridden this method. The implementation here combines the data from the subwidgets into a string in the format that *DateField* expects.

Built-in widgets

Django provides a representation of all the basic HTML widgets, plus some commonly used groups of widgets in the `django.forms.widgets` module, including the input of text, various checkboxes and selectors, uploading files, and handling of multi-valued input.

Widgets handling input of text

These widgets make use of the HTML elements `input` and `textarea`.

`TextInput`

```
class TextInput
```

- `input_type`: 'text'
- `template_name`: 'django/forms/widgets/text.html'
- Renders as: `<input type="text" ...>`

`NumberInput`

```
class NumberInput
```

- `input_type`: 'number'
- `template_name`: 'django/forms/widgets/number.html'
- Renders as: `<input type="number" ...>`

Beware that not all browsers support entering localized numbers in `number` input types. Django itself avoids using them for fields having their `localize` property set to `True`.

`EmailInput`

```
class EmailInput
```

- `input_type`: 'email'
- `template_name`: 'django/forms/widgets/email.html'
- Renders as: `<input type="email" ...>`

`URLInput`

```
class URLInput
```

- `input_type`: 'url'
- `template_name`: 'django/forms/widgets/url.html'
- Renders as: `<input type="url" ...>`

PasswordInput

class PasswordInput

- `input_type`: 'password'
- `template_name`: 'django/forms/widgets/password.html'
- Renders as: `<input type="password" ...>`

Takes one optional argument:

render_value

Determines whether the widget will have a value filled in when the form is re-displayed after a validation error (default is `False`).

HiddenInput

class HiddenInput

- `input_type`: 'hidden'
- `template_name`: 'django/forms/widgets/hidden.html'
- Renders as: `<input type="hidden" ...>`

Note that there also is a *MultipleHiddenInput* widget that encapsulates a set of hidden input elements.

DateInput

class DateInput

- `input_type`: 'text'
- `template_name`: 'django/forms/widgets/date.html'
- Renders as: `<input type="text" ...>`

Takes same arguments as *TextInput*, with one more optional argument:

format

The format in which this field's initial value will be displayed.

If no `format` argument is provided, the default format is the first format found in *DATE_INPUT_FORMATS* and respects *Format localization*.

`DateTimeInput`

```
class DateTimeInput
```

- `input_type`: 'text'
- `template_name`: 'django/forms/widgets/datetime.html'
- Renders as: `<input type="text" ...>`

Takes same arguments as *TextInput*, with one more optional argument:

format

The format in which this field's initial value will be displayed.

If no `format` argument is provided, the default format is the first format found in *DATETIME_INPUT_FORMATS* and respects *Format localization*.

By default, the microseconds part of the time value is always set to 0. If microseconds are required, use a subclass with the *supports_microseconds* attribute set to `True`.

`TimeInput`

```
class TimeInput
```

- `input_type`: 'text'
- `template_name`: 'django/forms/widgets/time.html'
- Renders as: `<input type="text" ...>`

Takes same arguments as *TextInput*, with one more optional argument:

format

The format in which this field's initial value will be displayed.

If no `format` argument is provided, the default format is the first format found in *TIME_INPUT_FORMATS* and respects *Format localization*.

For the treatment of microseconds, see *DateTimeInput*.

`Textarea`

```
class Textarea
```

- `template_name`: 'django/forms/widgets/textarea.html'
- Renders as: `<textarea>...</textarea>`

Selector and checkbox widgets

These widgets make use of the HTML elements `<select>`, `<input type="checkbox">`, and `<input type="radio">`.

Widgets that render multiple choices have an `option_template_name` attribute that specifies the template used to render each choice. For example, for the *Select* widget, `select_option.html` renders the `<option>` for a `<select>`.

CheckboxInput

`class CheckboxInput`

- `input_type`: 'checkbox'
- `template_name`: 'django/forms/widgets/checkbox.html'
- Renders as: `<input type="checkbox" ...>`

Takes one optional argument:

`check_test`

A callable that takes the value of the `CheckboxInput` and returns `True` if the checkbox should be checked for that value.

Select

`class Select`

- `template_name`: 'django/forms/widgets/select.html'
- `option_template_name`: 'django/forms/widgets/select_option.html'
- Renders as: `<select><option ...>...</select>`

`choices`

This attribute is optional when the form field does not have a `choices` attribute. If it does, it will override anything you set here when the attribute is updated on the *Field*.

NullBooleanSelect

```
class NullBooleanSelect
```

- `template_name`: 'django/forms/widgets/select.html'
- `option_template_name`: 'django/forms/widgets/select_option.html'

Select widget with options 'Unknown', 'Yes' and 'No'

SelectMultiple

```
class SelectMultiple
```

- `template_name`: 'django/forms/widgets/select.html'
- `option_template_name`: 'django/forms/widgets/select_option.html'

Similar to *Select*, but allows multiple selection: `<select multiple>...</select>`

RadioSelect

```
class RadioSelect
```

- `template_name`: 'django/forms/widgets/radio.html'
- `option_template_name`: 'django/forms/widgets/radio_option.html'

Similar to *Select*, but rendered as a list of radio buttons within `<div>` tags:

```
<div>
  <div><input type="radio" name="..."></div>
  ...
</div>
```

For more granular control over the generated markup, you can loop over the radio buttons in the template. Assuming a form `myform` with a field `beatles` that uses a `RadioSelect` as its widget:

```
<fieldset>
  <legend>{{ myform.beatles.label }}</legend>
  {% for radio in myform.beatles %}
  <div class="myradio">
    {{ radio }}
  </div>
  {% endfor %}
</fieldset>
```

This would generate the following HTML:

```

<fieldset>
    <legend>Radio buttons</legend>
    <div class="myradio">
        <label for="id_beatles_0"><input id="id_beatles_0" name="beatles" type="radio" value=
↪ "john" required> John</label>
    </div>
    <div class="myradio">
        <label for="id_beatles_1"><input id="id_beatles_1" name="beatles" type="radio" value=
↪ "paul" required> Paul</label>
    </div>
    <div class="myradio">
        <label for="id_beatles_2"><input id="id_beatles_2" name="beatles" type="radio" value=
↪ "george" required> George</label>
    </div>
    <div class="myradio">
        <label for="id_beatles_3"><input id="id_beatles_3" name="beatles" type="radio" value=
↪ "ringo" required> Ringo</label>
    </div>
</fieldset>

```

That included the `<label>` tags. To get more granular, you can use each radio button's tag, `choice_label` and `id_for_label` attributes. For example, this template...

```

<fieldset>
    <legend>{{ myform.beatles.label }}</legend>
    {% for radio in myform.beatles %}
    <label for="{{ radio.id_for_label }}">
        {{ radio.choice_label }}
        <span class="radio">{{ radio.tag }}</span>
    </label>
    {% endfor %}
</fieldset>

```

...will result in the following HTML:

```

<fieldset>
    <legend>Radio buttons</legend>
    <label for="id_beatles_0">
        John
        <span class="radio"><input id="id_beatles_0" name="beatles" type="radio" value="john"
↪ required></span>
    </label>
    <label for="id_beatles_1">
        Paul

```

(continues on next page)

(continued from previous page)

```

        <span class="radio"><input id="id_beatles_1" name="beatles" type="radio" value="paul"
↪required></span>
    </label>
    <label for="id_beatles_2">
        George
        <span class="radio"><input id="id_beatles_2" name="beatles" type="radio" value="george
↪" required></span>
    </label>
    <label for="id_beatles_3">
        Ringo
        <span class="radio"><input id="id_beatles_3" name="beatles" type="radio" value="ringo
↪" required></span>
    </label>
</fieldset>

```

If you decide not to loop over the radio buttons –e.g., if your template includes `{{ myform.beatles }}` –they’ll be output in a `<div>` with `<div>` tags, as above.

The outer `<div>` container receives the `id` attribute of the widget, if defined, or `BoundField.auto_id` otherwise.

When looping over the radio buttons, the `label` and `input` tags include `for` and `id` attributes, respectively. Each radio button has an `id_for_label` attribute to output the element’s ID.

CheckboxSelectMultiple

```
class CheckboxSelectMultiple
```

- `template_name`: 'django/forms/widgets/checkbox_select.html'
- `option_template_name`: 'django/forms/widgets/checkbox_option.html'

Similar to *SelectMultiple*, but rendered as a list of checkboxes:

```

<div>
  <div><input type="checkbox" name="..." ></div>
  ...
</div>

```

The outer `<div>` container receives the `id` attribute of the widget, if defined, or `BoundField.auto_id` otherwise.

Like *RadioSelect*, you can loop over the individual checkboxes for the widget’s choices. Unlike *RadioSelect*, the checkboxes won’t include the `required` HTML attribute if the field is required because browser validation would require all checkboxes to be checked instead of at least one.

When looping over the checkboxes, the `label` and `input` tags include `for` and `id` attributes, respectively. Each checkbox has an `id_for_label` attribute to output the element's ID.

File upload widgets

`FileInput`

```
class FileInput
```

- `template_name`: 'django/forms/widgets/file.html'
- Renders as: `<input type="file" ...>`

`ClearableFileInput`

```
class ClearableFileInput
```

- `template_name`: 'django/forms/widgets/clearable_file_input.html'
- Renders as: `<input type="file" ...>` with an additional checkbox input to clear the field's value, if the field is not required and has initial data.

Composite widgets

`MultipleHiddenInput`

```
class MultipleHiddenInput
```

- `template_name`: 'django/forms/widgets/multiple_hidden.html'
- Renders as: multiple `<input type="hidden" ...>` tags

A widget that handles multiple hidden widgets for fields that have a list of values.

`SplitDateTimeWidget`

```
class SplitDateTimeWidget
```

- `template_name`: 'django/forms/widgets/splitdatetime.html'

Wrapper (using *MultiWidget*) around two widgets: *DateInput* for the date, and *TimeInput* for the time. Must be used with *SplitDateTimeField* rather than *DateTimeField*.

`SplitDateTimeWidget` has several optional arguments:

date_format

Similar to *DateInput.format*

time_format

Similar to *TimeInput.format*

date_attrs

time_attrs

Similar to *Widget.attrs*. A dictionary containing HTML attributes to be set on the rendered *DateInput* and *TimeInput* widgets, respectively. If these attributes aren't set, *Widget.attrs* is used instead.

SplitHiddenDateTimeWidget

```
class SplitHiddenDateTimeWidget
```

- `template_name: 'django/forms/widgets/splithiddendatetime.html'`

Similar to *SplitDateTimeWidget*, but uses *HiddenInput* for both date and time.

SelectDateWidget

```
class SelectDateWidget
```

- `template_name: 'django/forms/widgets/select_date.html'`

Wrapper around three *Select* widgets: one each for month, day, and year.

Takes several optional arguments:

years

An optional list/tuple of years to use in the “year” select box. The default is a list containing the current year and the next 9 years.

months

An optional dict of months to use in the “months” select box.

The keys of the dict correspond to the month number (1-indexed) and the values are the displayed months:

```
MONTHS = {
    1: _("jan"),
    2: _("feb"),
    3: _("mar"),
    4: _("apr"),
```

(continues on next page)

(continued from previous page)

```

5: _("may"),
6: _("jun"),
7: _("jul"),
8: _("aug"),
9: _("sep"),
10: _("oct"),
11: _("nov"),
12: _("dec"),
}

```

empty_label

If the `DateField` is not required, `SelectDateWidget` will have an empty choice at the top of the list (which is --- by default). You can change the text of this label with the `empty_label` attribute. `empty_label` can be a string, list, or tuple. When a string is used, all select boxes will each have an empty choice with this label. If `empty_label` is a list or tuple of 3 string elements, the select boxes will have their own custom label. The labels should be in this order ('year_label', 'month_label', 'day_label').

```

# A custom empty label with string
field1 = forms.DateField(widget=SelectDateWidget(empty_label="Nothing"))

# A custom empty label with tuple
field1 = forms.DateField(
    widget=SelectDateWidget(
        empty_label=("Choose Year", "Choose Month", "Choose Day"),
    ),
)

```

6.12.7 Form and field validation

Form validation happens when the data is cleaned. If you want to customize this process, there are various places to make changes, each one serving a different purpose. Three types of cleaning methods are run during form processing. These are normally executed when you call the `is_valid()` method on a form. There are other things that can also trigger cleaning and validation (accessing the `errors` attribute or calling `full_clean()` directly), but normally they won't be needed.

In general, any cleaning method can raise `ValidationError` if there is a problem with the data it is processing, passing the relevant information to the `ValidationError` constructor. See below for the best practice in raising `ValidationError`. If no `ValidationError` is raised, the method should return the cleaned (normalized) data as a Python object.

Most validation can be done using `validators` - helpers that can be reused. Validators are functions (or callables) that take a single argument and raise `ValidationError` on invalid input. Validators are run after

the field's `to_python` and `validate` methods have been called.

Validation of a form is split into several steps, which can be customized or overridden:

- The `to_python()` method on a `Field` is the first step in every validation. It coerces the value to a correct datatype and raises `ValidationError` if that is not possible. This method accepts the raw value from the widget and returns the converted value. For example, a `FloatField` will turn the data into a Python `float` or raise a `ValidationError`.
- The `validate()` method on a `Field` handles field-specific validation that is not suitable for a validator. It takes a value that has been coerced to a correct datatype and raises `ValidationError` on any error. This method does not return anything and shouldn't alter the value. You should override it to handle validation logic that you can't or don't want to put in a validator.
- The `run_validators()` method on a `Field` runs all of the field's validators and aggregates all the errors into a single `ValidationError`. You shouldn't need to override this method.
- The `clean()` method on a `Field` subclass is responsible for running `to_python()`, `validate()`, and `run_validators()` in the correct order and propagating their errors. If, at any time, any of the methods raise `ValidationError`, the validation stops and that error is raised. This method returns the clean data, which is then inserted into the `cleaned_data` dictionary of the form.
- The `clean_<fieldname>()` method is called on a form subclass –where `<fieldname>` is replaced with the name of the form field attribute. This method does any cleaning that is specific to that particular attribute, unrelated to the type of field that it is. This method is not passed any parameters. You will need to look up the value of the field in `self.cleaned_data` and remember that it will be a Python object at this point, not the original string submitted in the form (it will be in `cleaned_data` because the general field `clean()` method, above, has already cleaned the data once).

For example, if you wanted to validate that the contents of a `CharField` called `serialnumber` was unique, `clean_serialnumber()` would be the right place to do this. You don't need a specific field (it's a `CharField`), but you want a formfield-specific piece of validation and, possibly, cleaning/normalizing the data.

The return value of this method replaces the existing value in `cleaned_data`, so it must be the field's value from `cleaned_data` (even if this method didn't change it) or a new cleaned value.

- The form subclass's `clean()` method can perform validation that requires access to multiple form fields. This is where you might put in checks such as “if field A is supplied, field B must contain a valid email address”. This method can return a completely different dictionary if it wishes, which will be used as the `cleaned_data`.

Since the field validation methods have been run by the time `clean()` is called, you also have access to the form's `errors` attribute which contains all the errors raised by cleaning of individual fields.

Note that any errors raised by your `Form.clean()` override will not be associated with any field in particular. They go into a special “field” (called `__all__`), which you can access via the `non_field_errors()` method if you need to. If you want to attach errors to a specific field in the

form, you need to call `add_error()`.

Also note that there are special considerations when overriding the `clean()` method of a `ModelForm` subclass. (see the [ModelForm documentation](#) for more information)

These methods are run in the order given above, one field at a time. That is, for each field in the form (in the order they are declared in the form definition), the `Field.clean()` method (or its override) is run, then `clean_<fieldname>()`. Finally, once those two methods are run for every field, the `Form.clean()` method, or its override, is executed whether or not the previous methods have raised errors.

Examples of each of these methods are provided below.

As mentioned, any of these methods can raise a `ValidationError`. For any field, if the `Field.clean()` method raises a `ValidationError`, any field-specific cleaning method is not called. However, the cleaning methods for all remaining fields are still executed.

Raising `ValidationError`

In order to make error messages flexible and easy to override, consider the following guidelines:

- Provide a descriptive error code to the constructor:

```
# Good
ValidationError(_("Invalid value"), code="invalid")

# Bad
ValidationError(_("Invalid value"))
```

- Don't coerce variables into the message; use placeholders and the `params` argument of the constructor:

```
# Good
ValidationError(
    _("Invalid value: %(value)s"),
    params={"value": "42"},
)

# Bad
ValidationError(_("Invalid value: %s") % value)
```

- Use mapping keys instead of positional formatting. This enables putting the variables in any order or omitting them altogether when rewriting the message:

```
# Good
ValidationError(
    _("Invalid value: %(value)s"),
    params={"value": "42"},
```

(continues on next page)

(continued from previous page)

```
)

# Bad
ValidationError(
    _("Invalid value: %s"),
    params={"42"},
)
```

- Wrap the message with `gettext` to enable translation:

```
# Good
ValidationError(_("Invalid value"))

# Bad
ValidationError("Invalid value")
```

Putting it all together:

```
raise ValidationError(
    _("Invalid value: %(value)s"),
    code="invalid",
    params={"value": "42"},
)
```

Following these guidelines is particularly necessary if you write reusable forms, form fields, and model fields.

While not recommended, if you are at the end of the validation chain (i.e. your form `clean()` method) and you know you will never need to override your error message you can still opt for the less verbose:

```
ValidationError(_("Invalid value: %s") % value)
```

The `Form.errors.as_data()` and `Form.errors.as_json()` methods greatly benefit from fully featured `ValidationErrors` (with a code name and a `params` dictionary).

Raising multiple errors

If you detect multiple errors during a cleaning method and wish to signal all of them to the form submitter, it is possible to pass a list of errors to the `ValidationError` constructor.

As above, it is recommended to pass a list of `ValidationError` instances with codes and `params` but a list of strings will also work:

```
# Good
raise ValidationError(
```

(continues on next page)

(continued from previous page)

```

    [
        ValidationError(_("Error 1"), code="error1"),
        ValidationError(_("Error 2"), code="error2"),
    ]
)

# Bad
raise ValidationError(
    [
        _("Error 1"),
        _("Error 2"),
    ]
)

```

Using validation in practice

The previous sections explained how validation works in general for forms. Since it can sometimes be easier to put things into place by seeing each feature in use, here are a series of small examples that use each of the previous features.

Using validators

Django's form (and model) fields support use of utility functions and classes known as validators. A validator is a callable object or function that takes a value and returns nothing if the value is valid or raises a *ValidationError* if not. These can be passed to a field's constructor, via the field's `validators` argument, or defined on the *Field* class itself with the `default_validators` attribute.

Validators can be used to validate values inside the field, let's have a look at Django's `SlugField`:

```

from django.core import validators
from django.forms import CharField

class SlugField(CharField):
    default_validators = [validators.validate_slug]

```

As you can see, `SlugField` is a `CharField` with a customized validator that validates that submitted text obeys to some character rules. This can also be done on field definition so:

```
slug = forms.SlugField()
```

is equivalent to:

```
slug = forms.CharField(validators=[validators.validate_slug])
```

Common cases such as validating against an email or a regular expression can be handled using existing validator classes available in Django. For example, `validators.validate_slug` is an instance of a *RegexValidator* constructed with the first argument being the pattern: `^[-a-zA-Z0-9_]+$`. See the section on [writing validators](#) to see a list of what is already available and for an example of how to write a validator.

Form field default cleaning

Let's first create a custom form field that validates its input is a string containing comma-separated email addresses. The full class looks like this:

```
from django import forms
from django.core.validators import validate_email

class MultiEmailField(forms.Field):
    def to_python(self, value):
        """Normalize data to a list of strings."""
        # Return an empty list if no input was given.
        if not value:
            return []
        return value.split(",")

    def validate(self, value):
        """Check if value consists only of valid emails."""
        # Use the parent's handling of required fields, etc.
        super().validate(value)
        for email in value:
            validate_email(email)
```

Every form that uses this field will have these methods run before anything else can be done with the field's data. This is cleaning that is specific to this type of field, regardless of how it is subsequently used.

Let's create a `ContactForm` to demonstrate how you'd use this field:

```
class ContactForm(forms.Form):
    subject = forms.CharField(max_length=100)
    message = forms.CharField()
    sender = forms.EmailField()
    recipients = MultiEmailField()
    cc_myself = forms.BooleanField(required=False)
```

Use `MultiEmailField` like any other form field. When the `is_valid()` method is called on the form, the `MultiEmailField.clean()` method will be run as part of the cleaning process and it will, in turn, call the custom `to_python()` and `validate()` methods.

Cleaning a specific field attribute

Continuing on from the previous example, suppose that in our `ContactForm`, we want to make sure that the `recipients` field always contains the address `"fred@example.com"`. This is validation that is specific to our form, so we don't want to put it into the general `MultiEmailField` class. Instead, we write a cleaning method that operates on the `recipients` field, like so:

```
from django import forms
from django.core.exceptions import ValidationError

class ContactForm(forms.Form):
    # Everything as before.
    ...

    def clean_recipients(self):
        data = self.cleaned_data["recipients"]
        if "fred@example.com" not in data:
            raise ValidationError("You have forgotten about Fred!")

        # Always return a value to use as the new cleaned data, even if
        # this method didn't change it.
        return data
```

Cleaning and validating fields that depend on each other

Suppose we add another requirement to our contact form: if the `cc_myself` field is `True`, the `subject` must contain the word `"help"`. We are performing validation on more than one field at a time, so the form's `clean()` method is a good spot to do this. Notice that we are talking about the `clean()` method on the form here, whereas earlier we were writing a `clean()` method on a field. It's important to keep the field and form difference clear when working out where to validate things. Fields are single data points, forms are a collection of fields.

By the time the form's `clean()` method is called, all the individual field clean methods will have been run (the previous two sections), so `self.cleaned_data` will be populated with any data that has survived so far. So you also need to remember to allow for the fact that the fields you are wanting to validate might not have survived the initial individual field checks.

There are two ways to report any errors from this step. Probably the most common method is to display the

error at the top of the form. To create such an error, you can raise a `ValidationError` from the `clean()` method. For example:

```
from django import forms
from django.core.exceptions import ValidationError

class ContactForm(forms.Form):
    # Everything as before.
    ...

    def clean(self):
        cleaned_data = super().clean()
        cc_myself = cleaned_data.get("cc_myself")
        subject = cleaned_data.get("subject")

        if cc_myself and subject:
            # Only do something if both fields are valid so far.
            if "help" not in subject:
                raise ValidationError(
                    "Did not send for 'help' in the subject despite " "CC'ing yourself."
                )
```

In this code, if the validation error is raised, the form will display an error message at the top of the form (normally) describing the problem. Such errors are non-field errors, which are displayed in the template with `{{ form.non_field_errors }}`.

The call to `super().clean()` in the example code ensures that any validation logic in parent classes is maintained. If your form inherits another that doesn't return a `cleaned_data` dictionary in its `clean()` method (doing so is optional), then don't assign `cleaned_data` to the result of the `super()` call and use `self.cleaned_data` instead:

```
def clean(self):
    super().clean()
    cc_myself = self.cleaned_data.get("cc_myself")
    ...
```

The second approach for reporting validation errors might involve assigning the error message to one of the fields. In this case, let's assign an error message to both the "subject" and "cc_myself" rows in the form display. Be careful when doing this in practice, since it can lead to confusing form output. We're showing what is possible here and leaving it up to you and your designers to work out what works effectively in your particular situation. Our new code (replacing the previous sample) looks like this:

```
from django import forms
```

(continues on next page)

(continued from previous page)

```
class ContactForm(forms.Form):
    # Everything as before.
    ...

    def clean(self):
        cleaned_data = super().clean()
        cc_myself = cleaned_data.get("cc_myself")
        subject = cleaned_data.get("subject")

        if cc_myself and subject and "help" not in subject:
            msg = "Must put 'help' in subject when cc'ing yourself."
            self.add_error("cc_myself", msg)
            self.add_error("subject", msg)
```

The second argument of `add_error()` can be a string, or preferably an instance of `ValidationError`. See [Raising ValidationError](#) for more details. Note that `add_error()` automatically removes the field from `cleaned_data`.

6.13 Logging

See also:

- [How to configure and use logging](#)
- [Django logging overview](#)

Django's logging module extends Python's builtin `logging`.

Logging is configured as part of the general Django `django.setup()` function, so it's always available unless explicitly disabled.

6.13.1 Django' s default logging configuration

By default, Django uses Python' s `logging.config.dictConfig` format.

Default logging conditions

The full set of default logging conditions are:

When `DEBUG` is `True`:

- The `django` logger sends messages in the `django` hierarchy (except `django.server`) at the `INFO` level or higher to the console.

When `DEBUG` is `False`:

- The `django` logger sends messages in the `django` hierarchy (except `django.server`) with `ERROR` or `CRITICAL` level to `AdminEmailHandler`.

Independently of the value of `DEBUG`:

- The `django.server` logger sends messages at the `INFO` level or higher to the console.

All loggers except `django.server` propagate logging to their parents, up to the root `django` logger. The `console` and `mail_admins` handlers are attached to the root logger to provide the behavior described above.

Python' s own defaults send records of level `WARNING` and higher to the console.

Default logging definition

Django' s default logging configuration inherits Python' s defaults. It' s available as `django.utils.log.DEFAULT_LOGGING` and defined in `django/utils/log.py`:

```
{
    "version": 1,
    "disable_existing_loggers": False,
    "filters": {
        "require_debug_false": {
            "()": "django.utils.log.RequireDebugFalse",
        },
        "require_debug_true": {
            "()": "django.utils.log.RequireDebugTrue",
        },
    },
    "formatters": {
        "django.server": {
            "()": "django.utils.log.ServerFormatter",
            "format": "[{server_time}] {message}",
```

(continues on next page)

(continued from previous page)

```

        "style": "{",
    },
},
"handlers": {
    "console": {
        "level": "INFO",
        "filters": ["require_debug_true"],
        "class": "logging.StreamHandler",
    },
    "django.server": {
        "level": "INFO",
        "class": "logging.StreamHandler",
        "formatter": "django.server",
    },
    "mail_admins": {
        "level": "ERROR",
        "filters": ["require_debug_false"],
        "class": "django.utils.log.AdminEmailHandler",
    },
},
"loggers": {
    "django": {
        "handlers": ["console", "mail_admins"],
        "level": "INFO",
    },
    "django.server": {
        "handlers": ["django.server"],
        "level": "INFO",
        "propagate": False,
    },
},
}

```

See [Configuring logging](#) on how to complement or replace this default logging configuration.

6.13.2 Django logging extensions

Django provides a number of utilities to handle the particular requirements of logging in a web server environment.

Loggers

Django provides several built-in loggers.

`django`

The parent logger for messages in the `django` [named logger hierarchy](#). Django does not post messages using this name. Instead, it uses one of the loggers below.

`django.request`

Log messages related to the handling of requests. 5XX responses are raised as `ERROR` messages; 4XX responses are raised as `WARNING` messages. Requests that are logged to the `django.security` logger aren't logged to `django.request`.

Messages to this logger have the following extra context:

- `status_code`: The HTTP response code associated with the request.
- `request`: The request object that generated the logging message.

`django.server`

Log messages related to the handling of requests received by the server invoked by the `runserver` command. HTTP 5XX responses are logged as `ERROR` messages, 4XX responses are logged as `WARNING` messages, and everything else is logged as `INFO`.

Messages to this logger have the following extra context:

- `status_code`: The HTTP response code associated with the request.
- `request`: The request object that generated the logging message.

`django.template`

Log messages related to the rendering of templates.

- Missing context variables are logged as `DEBUG` messages.

`django.db.backends`

Messages relating to the interaction of code with the database. For example, every application-level SQL statement executed by a request is logged at the `DEBUG` level to this logger.

Messages to this logger have the following extra context:

- `duration`: The time taken to execute the SQL statement.
- `sql`: The SQL statement that was executed.
- `params`: The parameters that were used in the SQL call.
- `alias`: The alias of the database used in the SQL call.

For performance reasons, SQL logging is only enabled when `settings.DEBUG` is set to `True`, regardless of the logging level or handlers that are installed.

This logging does not include framework-level initialization (e.g. `SET TIMEZONE`). Turn on query logging in your database if you wish to view all database queries.

Support for logging transaction management queries (`BEGIN`, `COMMIT`, and `ROLLBACK`) was added.

`django.security.*`

The security loggers will receive messages on any occurrence of *SuspiciousOperation* and other security-related errors. There is a sub-logger for each subtype of security error, including all `SuspiciousOperations`. The level of the log event depends on where the exception is handled. Most occurrences are logged as a warning, while any `SuspiciousOperation` that reaches the WSGI handler will be logged as an error. For example, when an `HTTPHost` header is included in a request from a client that does not match `ALLOWED_HOSTS`, Django will return a 400 response, and an error message will be logged to the `django.security.DisallowedHost` logger.

These log events will reach the `django` logger by default, which mails error events to admins when `DEBUG=False`. Requests resulting in a 400 response due to a `SuspiciousOperation` will not be logged to the `django.request` logger, but only to the `django.security` logger.

To silence a particular type of `SuspiciousOperation`, you can override that specific logger following this example:

```
LOGGING = {
    # ...
    "handlers": {
        "null": {
            "class": "logging.NullHandler",
        },
    },
    "loggers": {
        "django.security.DisallowedHost": {
            "handlers": ["null"],
            "propagate": False,
        },
    },
    # ...
}
```

Other `django.security` loggers not based on `SuspiciousOperation` are:

- `django.security.csrf`: For [CSRF failures](#).

`django.db.backends.schema`

Logs the SQL queries that are executed during schema changes to the database by the [migrations framework](#). Note that it won't log the queries executed by [RunPython](#). Messages to this logger have `params` and `sql` in their extra context (but unlike `django.db.backends`, not `duration`). The values have the same meaning as explained in [django.db.backends](#).

Handlers

Django provides one log handler in addition to [those provided by the Python logging module](#).

`class AdminEmailHandler(include_html=False, email_backend=None, reporter_class=None)`

This handler sends an email to the site [ADMINS](#) for each log message it receives.

If the log record contains a `request` attribute, the full details of the request will be included in the email. The email subject will include the phrase “internal IP” if the client's IP address is in the [INTERNAL_IPS](#) setting; if not, it will include “EXTERNAL IP”.

If the log record contains stack trace information, that stack trace will be included in the email.

The `include_html` argument of `AdminEmailHandler` is used to control whether the traceback email includes an HTML attachment containing the full content of the debug web page that would have been produced if [DEBUG](#) were `True`. To set this value in your configuration, include it in the handler definition for `django.utils.log.AdminEmailHandler`, like this:

```
"handlers": {
    "mail_admins": {
        "level": "ERROR",
        "class": "django.utils.log.AdminEmailHandler",
        "include_html": True,
    },
}
```

Be aware of the [security implications of logging](#) when using the `AdminEmailHandler`.

By setting the `email_backend` argument of `AdminEmailHandler`, the [email backend](#) that is being used by the handler can be overridden, like this:

```
"handlers": {
    "mail_admins": {
        "level": "ERROR",
        "class": "django.utils.log.AdminEmailHandler",
        "email_backend": "django.core.mail.backends.filebased.EmailBackend",
    },
}
```

By default, an instance of the email backend specified in `EMAIL_BACKEND` will be used.

The `reporter_class` argument of `AdminEmailHandler` allows providing an `django.views.debug.ExceptionReporter` subclass to customize the traceback text sent in the email body. You provide a string import path to the class you wish to use, like this:

```
"handlers": {
    "mail_admins": {
        "level": "ERROR",
        "class": "django.utils.log.AdminEmailHandler",
        "include_html": True,
        "reporter_class": "somepackage.error_reporter.CustomErrorReporter",
    },
}
```

send_mail(subject, message, *args, **kwargs)

Sends emails to admin users. To customize this behavior, you can subclass the [*AdminEmailHandler*](#) class and override this method.

Filters

Django provides some log filters in addition to those provided by the Python logging module.

class `CallbackFilter(callback)`

This filter accepts a callback function (which should accept a single argument, the record to be logged), and calls it for each record that passes through the filter. Handling of that record will not proceed if the callback returns `False`.

For instance, to filter out `UnreadablePostError` (raised when a user cancels an upload) from the admin emails, you would create a filter function:

```
from django.http import UnreadablePostError

def skip_unreadable_post(record):
    if record.exc_info:
        exc_type, exc_value = record.exc_info[:2]
        if isinstance(exc_value, UnreadablePostError):
            return False
    return True
```

and then add it to your logging config:

```
LOGGING = {
    # ...
    "filters": {
        "skip_unreadable_posts": {
            "()": "django.utils.log.CallbackFilter",
            "callback": skip_unreadable_post,
        },
    },
    "handlers": {
        "mail_admins": {
            "level": "ERROR",
            "filters": ["skip_unreadable_posts"],
            "class": "django.utils.log.AdminEmailHandler",
        },
    },
    # ...
}
```

class `RequireDebugFalse`

This filter will only pass on records when `settings.DEBUG` is `False`.

This filter is used as follows in the default `LOGGING` configuration to ensure that the `AdminEmailHandler`

only sends error emails to admins when *DEBUG* is False:

```
LOGGING = {
    # ...
    "filters": {
        "require_debug_false": {
            "()": "django.utils.log.RequireDebugFalse",
        },
    },
    "handlers": {
        "mail_admins": {
            "level": "ERROR",
            "filters": ["require_debug_false"],
            "class": "django.utils.log.AdminEmailHandler",
        },
    },
    # ...
}
```

class `RequireDebugTrue`

This filter is similar to *RequireDebugFalse*, except that records are passed only when *DEBUG* is True.

6.14 Middleware

This document explains all middleware components that come with Django. For information on how to use them and how to write your own middleware, see the [middleware usage guide](#).

6.14.1 Available middleware

Cache middleware

class `UpdateCacheMiddleware`

class `FetchFromCacheMiddleware`

Enable the site-wide cache. If these are enabled, each Django-powered page will be cached for as long as the *CACHE_MIDDLEWARE_SECONDS* setting defines. See the [cache documentation](#).

“Common” middleware

`class CommonMiddleware`

Adds a few conveniences for perfectionists:

- Forbids access to user agents in the `DISALLOWED_USER_AGENTS` setting, which should be a list of compiled regular expression objects.
- Performs URL rewriting based on the `APPEND_SLASH` and `PREPEND_WWW` settings.

If `APPEND_SLASH` is `True` and the initial URL doesn't end with a slash, and it is not found in the URLconf, then a new URL is formed by appending a slash at the end. If this new URL is found in the URLconf, then Django redirects the request to this new URL. Otherwise, the initial URL is processed as usual.

For example, `foo.com/bar` will be redirected to `foo.com/bar/` if you don't have a valid URL pattern for `foo.com/bar` but do have a valid pattern for `foo.com/bar/`.

If `PREPEND_WWW` is `True`, URLs that lack a leading “www.” will be redirected to the same URL with a leading “www.”

Both of these options are meant to normalize URLs. The philosophy is that each URL should exist in one, and only one, place. Technically a URL `foo.com/bar` is distinct from `foo.com/bar/` –a search-engine indexer would treat them as separate URLs –so it's best practice to normalize URLs.

If necessary, individual views may be excluded from the `APPEND_SLASH` behavior using the `no_append_slash()` decorator:

```
from django.views.decorators.common import no_append_slash

@no_append_slash
def sensitive_fbv(request, *args, **kwargs):
    """View to be excluded from APPEND_SLASH."""
    return HttpResponse()
```

- Sets the Content-Length header for non-streaming responses.

`CommonMiddleware.response_redirect_class`

Defaults to `HttpResponsePermanentRedirect`. Subclass `CommonMiddleware` and override the attribute to customize the redirects issued by the middleware.

`class BrokenLinkEmailsMiddleware`

- Sends broken link notification emails to `MANAGERS` (see [How to manage error reporting](#)).

GZip middleware

```
class GZipMiddleware
```

```
    max_random_bytes
```

Defaults to 100. Subclass `GZipMiddleware` and override the attribute to change the maximum number of random bytes that is included with compressed responses.

Note: Security researchers revealed that when compression techniques (including `GZipMiddleware`) are used on a website, the site may become exposed to a number of possible attacks.

To mitigate attacks, Django implements a technique called Heal The Breach (HTB). It adds up to 100 bytes (see [`max\_random\_bytes`](#)) of random bytes to each response to make the attacks less effective.

For more details, see the [BREACH paper \(PDF\)](#), [breachattack.com](#), and the [Heal The Breach \(HTB\) paper](#).

Mitigation for the BREACH attack was added.

The `django.middleware.gzip.GZipMiddleware` compresses content for browsers that understand GZip compression (all modern browsers).

This middleware should be placed before any other middleware that need to read or write the response body so that compression happens afterward.

It will NOT compress content if any of the following are true:

- The content body is less than 200 bytes long.
- The response has already set the `Content-Encoding` header.
- The request (the browser) hasn't sent an `Accept-Encoding` header containing `gzip`.

If the response has an `ETag` header, the `ETag` is made weak to comply with [RFC 9110#section-8.8.1](#).

You can apply GZip compression to individual views using the [`gzip\_page\(\)`](#) decorator.

Conditional GET middleware

```
class ConditionalGetMiddleware
```

Handles conditional GET operations. If the response doesn't have an `ETag` header, the middleware adds one if needed. If the response has an `ETag` or `Last-Modified` header, and the request has `If-None-Match` or `If-Modified-Since`, the response is replaced by an [`HttpResponseNotModified`](#).

Locale middleware

```
class LocaleMiddleware
```

Enables language selection based on data from the request. It customizes content for each user. See the [internationalization documentation](#).

```
LocaleMiddleware.response_redirect_class
```

Defaults to *HttpResponseRedirect*. Subclass *LocaleMiddleware* and override the attribute to customize the redirects issued by the middleware.

Message middleware

```
class MessageMiddleware
```

Enables cookie- and session-based message support. See the [messages documentation](#).

Security middleware

Warning: If your deployment situation allows, it's usually a good idea to have your front-end web server perform the functionality provided by the *SecurityMiddleware*. That way, if there are requests that aren't served by Django (such as static media or user-uploaded files), they will have the same protections as requests to your Django application.

```
class SecurityMiddleware
```

The `django.middleware.security.SecurityMiddleware` provides several security enhancements to the request/response cycle. Each one can be independently enabled or disabled with a setting.

- *SECURE_CONTENT_TYPE_NOSNIFF*
- *SECURE_CROSS_ORIGIN_OPENER_POLICY*
- *SECURE_HSTS_INCLUDE_SUBDOMAINS*
- *SECURE_HSTS_PRELOAD*
- *SECURE_HSTS_SECONDS*
- *SECURE_REDIRECT_EXEMPT*
- *SECURE_REFERRER_POLICY*
- *SECURE_SSL_HOST*
- *SECURE_SSL_REDIRECT*

HTTP Strict Transport Security

For sites that should only be accessed over HTTPS, you can instruct modern browsers to refuse to connect to your domain name via an insecure connection (for a given period of time) by setting the “[Strict-Transport-Security](#)” header. This reduces your exposure to some SSL-stripping man-in-the-middle (MITM) attacks.

`SecurityMiddleware` will set this header for you on all HTTPS responses if you set the [SECURE_HSTS_SECONDS](#) setting to a non-zero integer value.

When enabling HSTS, it’s a good idea to first use a small value for testing, for example, [SECURE_HSTS_SECONDS = 3600](#) for one hour. Each time a web browser sees the HSTS header from your site, it will refuse to communicate non-securely (using HTTP) with your domain for the given period of time. Once you confirm that all assets are served securely on your site (i.e. HSTS didn’t break anything), it’s a good idea to increase this value so that infrequent visitors will be protected (31536000 seconds, i.e. 1 year, is common).

Additionally, if you set the [SECURE_HSTS_INCLUDE_SUBDOMAINS](#) setting to `True`, `SecurityMiddleware` will add the `includeSubDomains` directive to the `Strict-Transport-Security` header. This is recommended (assuming all subdomains are served exclusively using HTTPS), otherwise your site may still be vulnerable via an insecure connection to a subdomain.

If you wish to submit your site to the [browser preload list](#), set the [SECURE_HSTS_PRELOAD](#) setting to `True`. That appends the `preload` directive to the `Strict-Transport-Security` header.

Warning: The HSTS policy applies to your entire domain, not just the URL of the response that you set the header on. Therefore, you should only use it if your entire domain is served via HTTPS only.

Browsers properly respecting the HSTS header will refuse to allow users to bypass warnings and connect to a site with an expired, self-signed, or otherwise invalid SSL certificate. If you use HSTS, make sure your certificates are in good shape and stay that way!

Note: If you are deployed behind a load-balancer or reverse-proxy server, and the `Strict-Transport-Security` header is not being added to your responses, it may be because Django doesn’t realize that it’s on a secure connection; you may need to set the [SECURE_PROXY_SSL_HEADER](#) setting.

Referrer Policy

Browsers use [the Referer header](#) as a way to send information to a site about how users got there. When a user clicks a link, the browser will send the full URL of the linking page as the referrer. While this can be useful for some purposes –like figuring out who’s linking to your site –it also can cause privacy concerns by informing one site that a user was visiting another site.

Some browsers have the ability to accept hints about whether they should send the HTTP `Referer` header when a user clicks a link; this hint is provided via [the Referrer-Policy header](#). This header can suggest any of three behaviors to browsers:

- Full URL: send the entire URL in the `Referer` header. For example, if the user is visiting `https://example.com/page.html`, the `Referer` header would contain `"https://example.com/page.html"`.
- Origin only: send only the “origin” in the referrer. The origin consists of the scheme, host and (optionally) port number. For example, if the user is visiting `https://example.com/page.html`, the origin would be `https://example.com/`.
- No referrer: do not send a `Referer` header at all.

There are two types of conditions this header can tell a browser to watch out for:

- Same-origin versus cross-origin: a link from `https://example.com/1.html` to `https://example.com/2.html` is same-origin. A link from `https://example.com/page.html` to `https://not.example.com/page.html` is cross-origin.
- Protocol downgrade: a downgrade occurs if the page containing the link is served via HTTPS, but the page being linked to is not served via HTTPS.

Warning: When your site is served via HTTPS, [Django’s CSRF protection system](#) requires the `Referer` header to be present, so completely disabling the `Referer` header will interfere with CSRF protection. To gain most of the benefits of disabling `Referer` headers while also keeping CSRF protection, consider enabling only same-origin referrers.

`SecurityMiddleware` can set the `Referrer-Policy` header for you, based on the [SECURE_REFERRER_POLICY](#) setting (note spelling: browsers send a `Referer` header when a user clicks a link, but the header instructing a browser whether to do so is spelled `Referrer-Policy`). The valid values for this setting are:

no-referrer

Instructs the browser to send no referrer for links clicked on this site.

no-referrer-when-downgrade

Instructs the browser to send a full URL as the referrer, but only when no protocol downgrade occurs.

origin

Instructs the browser to send only the origin, not the full URL, as the referrer.

origin-when-cross-origin

Instructs the browser to send the full URL as the referrer for same-origin links, and only the origin for cross-origin links.

same-origin

Instructs the browser to send a full URL, but only for same-origin links. No referrer will be sent for cross-origin links.

strict-origin

Instructs the browser to send only the origin, not the full URL, and to send no referrer when a protocol downgrade occurs.

strict-origin-when-cross-origin

Instructs the browser to send the full URL when the link is same-origin and no protocol downgrade occurs; send only the origin when the link is cross-origin and no protocol downgrade occurs; and no referrer when a protocol downgrade occurs.

unsafe-url

Instructs the browser to always send the full URL as the referrer.

Unknown Policy Values

Where a policy value is `unknown` by a user agent, it is possible to specify multiple policy values to provide a fallback. The last specified value that is understood takes precedence. To support this, an iterable or comma-separated string can be used with `SECURE_REFERRER_POLICY`.

Cross-Origin Opener Policy

Some browsers have the ability to isolate top-level windows from other documents by putting them in a separate browsing context group based on the value of the **Cross-Origin Opener Policy** (COOP) header. If a document that is isolated in this way opens a cross-origin popup window, the popup's `window.opener` property will be `null`. Isolating windows using COOP is a defense-in-depth protection against cross-origin attacks, especially those like Spectre which allowed exfiltration of data loaded into a shared browsing context.

`SecurityMiddleware` can set the `Cross-Origin-Opener-Policy` header for you, based on the `SECURE_CROSS_ORIGIN_OPENER_POLICY` setting. The valid values for this setting are:

same-origin

Isolates the browsing context exclusively to same-origin documents. Cross-origin documents are not loaded in the same browsing context. This is the default and most secure option.

same-origin-allow-popups

Isolates the browsing context to same-origin documents or those which either don't set COOP or which opt out of isolation by setting a COOP of `unsafe-none`.

unsafe-none

Allows the document to be added to its opener's browsing context group unless the opener itself has a COOP of `same-origin` or `same-origin-allow-popups`.

X-Content-Type-Options: nosniff

Some browsers will try to guess the content types of the assets that they fetch, overriding the `Content-Type` header. While this can help display sites with improperly configured servers, it can also pose a security risk.

If your site serves user-uploaded files, a malicious user could upload a specially-crafted file that would be interpreted as HTML or JavaScript by the browser when you expected it to be something harmless.

To prevent the browser from guessing the content type and force it to always use the type provided in the `Content-Type` header, you can pass the `X-Content-Type-Options: nosniff` header. `SecurityMiddleware` will do this for all responses if the `SECURE_CONTENT_TYPE_NOSNIFF` setting is `True`.

Note that in most deployment situations where Django isn't involved in serving user-uploaded files, this setting won't help you. For example, if your `MEDIA_URL` is served directly by your front-end web server (nginx, Apache, etc.) then you'd want to set this header there. On the other hand, if you are using Django to do something like require authorization in order to download files and you cannot set the header using your web server, this setting will be useful.

SSL Redirect

If your site offers both HTTP and HTTPS connections, most users will end up with an unsecured connection by default. For best security, you should redirect all HTTP connections to HTTPS.

If you set the `SECURE_SSL_REDIRECT` setting to `True`, `SecurityMiddleware` will permanently (HTTP 301) redirect all HTTP connections to HTTPS.

Note: For performance reasons, it's preferable to do these redirects outside of Django, in a front-end load balancer or reverse-proxy server such as `nginx`. `SECURE_SSL_REDIRECT` is intended for the deployment situations where this isn't an option.

If the `SECURE_SSL_HOST` setting has a value, all redirects will be sent to that host instead of the originally-requested host.

If there are a few pages on your site that should be available over HTTP, and not redirected to HTTPS, you can list regular expressions to match those URLs in the `SECURE_REDIRECT_EXEMPT` setting.

Note: If you are deployed behind a load-balancer or reverse-proxy server and Django can't seem to tell when a request actually is already secure, you may need to set the `SECURE_PROXY_SSL_HEADER` setting.

Session middleware

```
class SessionMiddleware
```

Enables session support. See the [session documentation](#).

Site middleware

```
class CurrentSiteMiddleware
```

Adds the `site` attribute representing the current site to every incoming `HttpRequest` object. See the [sites documentation](#).

Authentication middleware

```
class AuthenticationMiddleware
```

Adds the `user` attribute, representing the currently-logged-in user, to every incoming `HttpRequest` object. See [Authentication in web requests](#).

```
class RemoteUserMiddleware
```

Middleware for utilizing web server provided authentication. See [How to authenticate using REMOTE_USER](#) for usage details.

```
class PersistentRemoteUserMiddleware
```

Middleware for utilizing web server provided authentication when enabled only on the login page. See [Using REMOTE_USER on login pages only](#) for usage details.

CSRF protection middleware

```
class CsrfViewMiddleware
```

Adds protection against Cross Site Request Forgeries by adding hidden form fields to POST forms and checking requests for the correct value. See the [Cross Site Request Forgery protection documentation](#).

X-Frame-Options middleware

```
class XFrameOptionsMiddleware
```

Simple [clickjacking](#) protection via the X-Frame-Options header.

6.14.2 Middleware ordering

Here are some hints about the ordering of various Django middleware classes:

1. *SecurityMiddleware*

It should go near the top of the list if you're going to turn on the SSL redirect as that avoids running through a bunch of other unnecessary middleware.

2. *UpdateCacheMiddleware*

Before those that modify the Vary header (*SessionMiddleware*, *GZipMiddleware*, *LocaleMiddleware*).

3. *GZipMiddleware*

Before any middleware that may change or use the response body.

After *UpdateCacheMiddleware*: Modifies Vary header.

4. *SessionMiddleware*

Before any middleware that may raise an exception to trigger an error view (such as *PermissionDenied*) if you're using *CSRF_USE_SESSIONS*.

After *UpdateCacheMiddleware*: Modifies Vary header.

5. *ConditionalGetMiddleware*

Before any middleware that may change the response (it sets the ETag header).

After *GZipMiddleware* so it won't calculate an ETag header on gzipped contents.

6. *LocaleMiddleware*

One of the topmost, after *SessionMiddleware* (uses session data) and *UpdateCacheMiddleware* (modifies Vary header).

7. *CommonMiddleware*

Before any middleware that may change the response (it sets the Content-Length header). A middleware that appears before *CommonMiddleware* and changes the response must reset Content-Length.

Close to the top: it redirects when *APPEND_SLASH* or *PREPEND_WWW* are set to True.

After *SessionMiddleware* if you're using *CSRF_USE_SESSIONS*.

8. *CsrfViewMiddleware*

Before any view middleware that assumes that CSRF attacks have been dealt with.

Before *RemoteUserMiddleware*, or any other authentication middleware that may perform a login, and hence rotate the CSRF token, before calling down the middleware chain.

After *SessionMiddleware* if you're using *CSRF_USE_SESSIONS*.

9. *AuthenticationMiddleware*

After `SessionMiddleware`: uses session storage.

10. *MessageMiddleware*

After `SessionMiddleware`: can use session-based storage.

11. *FetchFromCacheMiddleware*

After any middleware that modifies the `Vary` header: that header is used to pick a value for the cache hash-key.

12. *FlatpageFallbackMiddleware*

Should be near the bottom as it's a last-resort type of middleware.

13. *RedirectFallbackMiddleware*

Should be near the bottom as it's a last-resort type of middleware.

6.15 Migration Operations

Migration files are composed of one or more `Operations`, objects that declaratively record what the migration should do to your database.

Django also uses these `Operation` objects to work out what your models looked like historically, and to calculate what changes you've made to your models since the last migration so it can automatically write your migrations; that's why they're declarative, as it means Django can easily load them all into memory and run through them without touching the database to work out what your project should look like.

There are also more specialized `Operation` objects which are for things like [data migrations](#) and for advanced manual database manipulation. You can also write your own `Operation` classes if you want to encapsulate a custom change you commonly make.

If you need an empty migration file to write your own `Operation` objects into, use `python manage.py makemigrations --empty yourappname`, but be aware that manually adding schema-altering operations can confuse the migration autodetector and make resulting runs of `makemigrations` output incorrect code.

All of the core Django operations are available from the `django.db.migrations.operations` module.

For introductory material, see the [migrations topic guide](#).

6.15.1 Schema Operations

CreateModel

```
class CreateModel(name, fields, options=None, bases=None, managers=None)
```

Creates a new model in the project history and a corresponding table in the database to match it.

`name` is the model name, as would be written in the `models.py` file.

`fields` is a list of 2-tuples of (`field_name`, `field_instance`). The field instance should be an unbound field (so just `models.CharField(...)`, rather than a field taken from another model).

`options` is an optional dictionary of values from the model's `Meta` class.

`bases` is an optional list of other classes to have this model inherit from; it can contain both class objects as well as strings in the format "`appname.ModelName`" if you want to depend on another model (so you inherit from the historical version). If it's not supplied, it defaults to inheriting from the standard `models.Model`.

`managers` takes a list of 2-tuples of (`manager_name`, `manager_instance`). The first manager in the list will be the default manager for this model during migrations.

DeleteModel

```
class DeleteModel(name)
```

Deletes the model from the project history and its table from the database.

RenameModel

```
class RenameModel(old_name, new_name)
```

Renames the model from an old name to a new one.

You may have to manually add this if you change the model's name and quite a few of its fields at once; to the autodetector, this will look like you deleted a model with the old name and added a new one with a different name, and the migration it creates will lose any data in the old table.

AlterModelTable

```
class AlterModelTable(name, table)
```

Changes the model's table name (the `db_table` option on the `Meta` subclass).

AlterModelTableComment

```
class AlterModelTableComment(name, table_comment)
```

Changes the model's table comment (the *db_table_comment* option on the *Meta* subclass).

AlterUniqueTogether

```
class AlterUniqueTogether(name, unique_together)
```

Changes the model's set of unique constraints (the *unique_together* option on the *Meta* subclass).

AlterIndexTogether

```
class AlterIndexTogether(name, index_together)
```

Changes the model's set of custom indexes (the *index_together* option on the *Meta* subclass).

Warning: *AlterIndexTogether* is officially supported only for pre-Django 4.2 migration files. For backward compatibility reasons, it's still part of the public API, and there's no plan to deprecate or remove it, but it should not be used for new migrations. Use *AddIndex* and *RemoveIndex* operations instead.

AlterOrderWithRespectTo

```
class AlterOrderWithRespectTo(name, order_with_respect_to)
```

Makes or deletes the *_order* column needed for the *order_with_respect_to* option on the *Meta* subclass.

AlterModelOptions

```
class AlterModelOptions(name, options)
```

Stores changes to miscellaneous model options (settings on a model's *Meta*) like *permissions* and *verbose_name*. Does not affect the database, but persists these changes for *RunPython* instances to use. *options* should be a dictionary mapping option names to values.

AlterModelManagers

```
class AlterModelManagers(name, managers)
```

Alters the managers that are available during migrations.

AddField

```
class AddField(model_name, name, field, preserve_default=True)
```

Adds a field to a model. `model_name` is the model's name, `name` is the field's name, and `field` is an unbound Field instance (the thing you would put in the field declaration in `models.py` - for example, `models.IntegerField(null=True)`).

The `preserve_default` argument indicates whether the field's default value is permanent and should be baked into the project state (`True`), or if it is temporary and just for this migration (`False`) - usually because the migration is adding a non-nullable field to a table and needs a default value to put into existing rows. It does not affect the behavior of setting defaults in the database directly - Django never sets database defaults and always applies them in the Django ORM code.

Warning: On older databases, adding a field with a default value may cause a full rewrite of the table. This happens even for nullable fields and may have a negative performance impact. To avoid that, the following steps should be taken.

- Add the nullable field without the default value and run the *makemigrations* command. This should generate a migration with an `AddField` operation.
- Add the default value to your field and run the *makemigrations* command. This should generate a migration with an `AlterField` operation.

RemoveField

```
class RemoveField(model_name, name)
```

Removes a field from a model.

Bear in mind that when reversed, this is actually adding a field to a model. The operation is reversible (apart from any data loss, which is irreversible) if the field is nullable or if it has a default value that can be used to populate the recreated column. If the field is not nullable and does not have a default value, the operation is irreversible.

AlterField

```
class AlterField(model_name, name, field, preserve_default=True)
```

Alters a field's definition, including changes to its type, *null*, *unique*, *db_column* and other field attributes.

The `preserve_default` argument indicates whether the field's default value is permanent and should be baked into the project state (`True`), or if it is temporary and just for this migration (`False`) - usually because the migration is altering a nullable field to a non-nullable one and needs a default value to put into existing rows. It does not affect the behavior of setting defaults in the database directly - Django never sets database defaults and always applies them in the Django ORM code.

Note that not all changes are possible on all databases - for example, you cannot change a text-type field like `models.TextField()` into a number-type field like `models.IntegerField()` on most databases.

RenameField

```
class RenameField(model_name, old_name, new_name)
```

Changes a field's name (and, unless *db_column* is set, its column name).

AddIndex

```
class AddIndex(model_name, index)
```

Creates an index in the database table for the model with `model_name`. `index` is an instance of the *Index* class.

RemoveIndex

```
class RemoveIndex(model_name, name)
```

Removes the index named `name` from the model with `model_name`.

RenameIndex

```
class RenameIndex(model_name, new_name, old_name=None, old_fields=None)
```

Renames an index in the database table for the model with `model_name`. Exactly one of `old_name` and `old_fields` can be provided. `old_fields` is an iterable of the strings, often corresponding to fields of *index_together*.

On databases that don't support an index renaming statement (SQLite and MariaDB < 10.5.2), the operation will drop and recreate the index, which can be expensive.

AddConstraint

```
class AddConstraint(model_name, constraint)
```

Creates a [constraint](#) in the database table for the model with `model_name`.

RemoveConstraint

```
class RemoveConstraint(model_name, name)
```

Removes the constraint named `name` from the model with `model_name`.

6.15.2 Special Operations

RunSQL

```
class RunSQL(sql, reverse_sql=None, state_operations=None, hints=None, elidable=False)
```

Allows running of arbitrary SQL on the database - useful for more advanced features of database backends that Django doesn't support directly.

`sql`, and `reverse_sql` if provided, should be strings of SQL to run on the database. On most database backends (all but PostgreSQL), Django will split the SQL into individual statements prior to executing them.

Warning: On PostgreSQL and SQLite, only use `BEGIN` or `COMMIT` in your SQL in [non-atomic migrations](#), to avoid breaking Django's transaction state.

You can also pass a list of strings or 2-tuples. The latter is used for passing queries and parameters in the same way as `cursor.execute()`. These three operations are equivalent:

```
migrations.RunSQL("INSERT INTO musician (name) VALUES ('Reinhardt');")
migrations.RunSQL([("INSERT INTO musician (name) VALUES ('Reinhardt');", None)])
migrations.RunSQL([("INSERT INTO musician (name) VALUES (%s);", ["Reinhardt"])]])
```

If you want to include literal percent signs in the query, you have to double them if you are passing parameters.

The `reverse_sql` queries are executed when the migration is unapplied. They should undo what is done by the `sql` queries. For example, to undo the above insertion with a deletion:

```
migrations.RunSQL(
    sql=[("INSERT INTO musician (name) VALUES (%s);", ["Reinhardt"])],
    reverse_sql=[("DELETE FROM musician where name=%s;", ["Reinhardt"])],
)
```

If `reverse_sql` is `None` (the default), the `RunSQL` operation is irreversible.

The `state_operations` argument allows you to supply operations that are equivalent to the SQL in terms of project state. For example, if you are manually creating a column, you should pass in a list containing an `AddField` operation here so that the autodetector still has an up-to-date state of the model. If you don't, when you next run `makemigrations`, it won't see any operation that adds that field and so will try to run it again. For example:

```
migrations.RunSQL(
    "ALTER TABLE musician ADD COLUMN name varchar(255) NOT NULL;",
    state_operations=[
        migrations.AddField(
            "musician",
            "name",
            models.CharField(max_length=255),
        ),
    ],
)
```

The optional `hints` argument will be passed as `**hints` to the `allow_migrate()` method of database routers to assist them in making routing decisions. See [Hints](#) for more details on database hints.

The optional `elidable` argument determines whether or not the operation will be removed (elided) when squashing migrations.

`RunSQL.noop`

Pass the `RunSQL.noop` attribute to `sql` or `reverse_sql` when you want the operation not to do anything in the given direction. This is especially useful in making the operation reversible.

`RunPython`

```
class RunPython(code, reverse_code=None, atomic=None, hints=None, elidable=False)
```

Runs custom Python code in a historical context. `code` (and `reverse_code` if supplied) should be callable objects that accept two arguments; the first is an instance of `django.apps.registry.Apps` containing historical models that match the operation's place in the project history, and the second is an instance of `SchemaEditor`.

The `reverse_code` argument is called when unapplying migrations. This callable should undo what is done in the `code` callable so that the migration is reversible. If `reverse_code` is `None` (the default), the `RunPython` operation is irreversible.

The optional `hints` argument will be passed as `**hints` to the `allow_migrate()` method of database routers to assist them in making a routing decision. See [Hints](#) for more details on database hints.

The optional `elidable` argument determines whether or not the operation will be removed (elided) when squashing migrations.

You are advised to write the code as a separate function above the `Migration` class in the migration file, and pass it to `RunPython`. Here's an example of using `RunPython` to create some initial objects on a `Country` model:

```
from django.db import migrations

def forwards_func(apps, schema_editor):
    # We get the model from the versioned app registry;
    # if we directly import it, it'll be the wrong version
    Country = apps.get_model("myapp", "Country")
    db_alias = schema_editor.connection.alias
    Country.objects.using(db_alias).bulk_create(
        [
            Country(name="USA", code="us"),
            Country(name="France", code="fr"),
        ]
    )

def reverse_func(apps, schema_editor):
    # forwards_func() creates two Country instances,
    # so reverse_func() should delete them.
    Country = apps.get_model("myapp", "Country")
    db_alias = schema_editor.connection.alias
    Country.objects.using(db_alias).filter(name="USA", code="us").delete()
    Country.objects.using(db_alias).filter(name="France", code="fr").delete()

class Migration(migrations.Migration):
    dependencies = []

    operations = [
        migrations.RunPython(forwards_func, reverse_func),
    ]
```

This is generally the operation you would use to create [data migrations](#), run custom data updates and alterations, and anything else you need access to an ORM and/or Python code for.

Much like [RunSQL](#), ensure that if you change schema inside here you're either doing it outside the scope of the Django model system (e.g. triggers) or that you use [SeparateDatabaseAndState](#) to add in operations that will reflect your changes to the model state - otherwise, the versioned ORM and the autodetector will stop working correctly.

By default, `RunPython` will run its contents inside a transaction on databases that do not support DDL transactions (for example, MySQL and Oracle). This should be safe, but may cause a crash if you attempt to use

the `schema_editor` provided on these backends; in this case, pass `atomic=False` to the `RunPython` operation.

On databases that do support DDL transactions (SQLite and PostgreSQL), `RunPython` operations do not have any transactions automatically added besides the transactions created for each migration. Thus, on PostgreSQL, for example, you should avoid combining schema changes and `RunPython` operations in the same migration or you may hit errors like `OperationalError: cannot ALTER TABLE "mytable" because it has pending trigger events`.

If you have a different database and aren't sure if it supports DDL transactions, check the `django.db.connection.features.can_rollback_ddl` attribute.

If the `RunPython` operation is part of a [non-atomic migration](#), the operation will only be executed in a transaction if `atomic=True` is passed to the `RunPython` operation.

Warning: `RunPython` does not magically alter the connection of the models for you; any model methods you call will go to the default database unless you give them the current database alias (available from `schema_editor.connection.alias`, where `schema_editor` is the second argument to your function).

static `RunPython.noop()`

Pass the `RunPython.noop` method to `code` or `reverse_code` when you want the operation not to do anything in the given direction. This is especially useful in making the operation reversible.

`SeparateDatabaseAndState`

class `SeparateDatabaseAndState`(`database_operations=None`, `state_operations=None`)

A highly specialized operation that lets you mix and match the database (schema-changing) and state (autodetector-powering) aspects of operations.

It accepts two lists of operations. When asked to apply state, it will use the `state_operations` list (this is a generalized version of `RunSQL`'s `state_operations` argument). When asked to apply changes to the database, it will use the `database_operations` list.

If the actual state of the database and Django's view of the state get out of sync, this can break the migration framework, even leading to data loss. It's worth exercising caution and checking your database and state operations carefully. You can use `sqlmigrate` and `dbshell` to check your database operations. You can use `makemigrations`, especially with `--dry-run`, to check your state operations.

For an example using `SeparateDatabaseAndState`, see [Changing a ManyToManyField to use a through model](#).

6.15.3 Writing your own

Operations have a relatively simple API, and they're designed so that you can easily write your own to supplement the built-in Django ones. The basic structure of an `Operation` looks like this:

```
from django.db.migrations.operations.base import Operation

class MyCustomOperation(Operation):
    # If this is False, it means that this operation will be ignored by
    # sqlmigrate; if true, it will be run and the SQL collected for its output.
    reduces_to_sql = False

    # If this is False, Django will refuse to reverse past this operation.
    reversible = False

    def __init__(self, arg1, arg2):
        # Operations are usually instantiated with arguments in migration
        # files. Store the values of them on self for later use.
        pass

    def state_forwards(self, app_label, state):
        # The Operation should take the 'state' parameter (an instance of
        # django.db.migrations.state.ProjectState) and mutate it to match
        # any schema changes that have occurred.
        pass

    def database_forwards(self, app_label, schema_editor, from_state, to_state):
        # The Operation should use schema_editor to apply any changes it
        # wants to make to the database.
        pass

    def database_backwards(self, app_label, schema_editor, from_state, to_state):
        # If reversible is True, this is called when the operation is reversed.
        pass

    def describe(self):
        # This is used to describe what the operation does in console output.
        return "Custom Operation"

    @property
    def migration_name_fragment(self):
        # Optional. A filename part suitable for automatically naming a
        # migration containing this operation, or None if not applicable.
        return "custom_operation_%s_%s" % (self.arg1, self.arg2)
```

You can take this template and work from it, though we suggest looking at the built-in Django operations in `django.db.migrations.operations` - they cover a lot of the example usage of semi-internal aspects of the migration framework like `ProjectState` and the patterns used to get historical models, as well as `ModelState` and the patterns used to mutate historical models in `state_forwards()`.

Some things to note:

- You don't need to learn too much about `ProjectState` to write migrations; just know that it has an `apps` property that gives access to an app registry (which you can then call `get_model` on).
- `database_forwards` and `database_backwards` both get two states passed to them; these represent the difference the `state_forwards` method would have applied, but are given to you for convenience and speed reasons.
- If you want to work with model classes or model instances from the `from_state` argument in `database_forwards()` or `database_backwards()`, you must render model states using the `clear_delayed_apps_cache()` method to make related models available:

```
def database_forwards(self, app_label, schema_editor, from_state, to_state):
    # This operation should have access to all models. Ensure that all models are
    # reloaded in case any are delayed.
    from_state.clear_delayed_apps_cache()
    ...
```

- `to_state` in the `database_backwards` method is the older state; that is, the one that will be the current state once the migration has finished reversing.
- You might see implementations of `references_model` on the built-in operations; this is part of the autodetection code and does not matter for custom operations.

Warning: For performance reasons, the `Field` instances in `ModelState.fields` are reused across migrations. You must never change the attributes on these instances. If you need to mutate a field in `state_forwards()`, you must remove the old instance from `ModelState.fields` and add a new instance in its place. The same is true for the `Manager` instances in `ModelState.managers`.

As an example, let's make an operation that loads PostgreSQL extensions (which contain some of PostgreSQL's more exciting features). Since there's no model state changes, all it does is run one command:

```
from django.db.migrations.operations.base import Operation

class LoadExtension(Operation):
    reversible = True

    def __init__(self, name):
```

(continues on next page)

(continued from previous page)

```
self.name = name

def state_forwards(self, app_label, state):
    pass

def database_forwards(self, app_label, schema_editor, from_state, to_state):
    schema_editor.execute("CREATE EXTENSION IF NOT EXISTS %s" % self.name)

def database_backwards(self, app_label, schema_editor, from_state, to_state):
    schema_editor.execute("DROP EXTENSION %s" % self.name)

def describe(self):
    return "Creates extension %s" % self.name

@property
def migration_name_fragment(self):
    return "create_extension_%s" % self.name
```

6.16 Models

Model API reference. For introductory material, see [Models](#).

6.16.1 Model field reference

This document contains all the API references of *Field* including the [field options](#) and [field types](#) Django offers.

See also:

If the built-in fields don't do the trick, you can try [django-localflavor](#) ([documentation](#)), which contains assorted pieces of code that are useful for particular countries and cultures.

Also, you can easily [write your own custom model fields](#).

Note: Technically, these models are defined in `django.db.models.fields`, but for convenience they're imported into `django.db.models`; the standard convention is to use `from django.db import models` and refer to fields as `models.<Foo>Field`.

Field options

The following arguments are available to all field types. All are optional.

`null`

`Field.null`

If `True`, Django will store empty values as `NULL` in the database. Default is `False`.

Avoid using `null` on string-based fields such as `CharField` and `TextField`. If a string-based field has `null=True`, that means it has two possible values for “no data”: `NULL`, and the empty string. In most cases, it’s redundant to have two possible values for “no data;” the Django convention is to use the empty string, not `NULL`. One exception is when a `CharField` has both `unique=True` and `blank=True` set. In this situation, `null=True` is required to avoid unique constraint violations when saving multiple objects with blank values.

For both string-based and non-string-based fields, you will also need to set `blank=True` if you wish to permit empty values in forms, as the `null` parameter only affects database storage (see `blank`).

Note: When using the Oracle database backend, the value `NULL` will be stored to denote the empty string regardless of this attribute.

`blank`

`Field.blank`

If `True`, the field is allowed to be blank. Default is `False`.

Note that this is different than `null`. `null` is purely database-related, whereas `blank` is validation-related. If a field has `blank=True`, form validation will allow entry of an empty value. If a field has `blank=False`, the field will be required.

Supplying missing values

`blank=True` can be used with fields having `null=False`, but this will require implementing `clean()` on the model in order to programmatically supply any missing values.

`choices`

`Field.choices`

A [sequence](#) consisting itself of iterables of exactly two items (e.g. [(A, B), (A, B) ...]) to use as choices for this field. If choices are given, they're enforced by [model validation](#) and the default form widget will be a select box with these choices instead of the standard text field.

The first element in each tuple is the actual value to be set on the model, and the second element is the human-readable name. For example:

```
YEAR_IN_SCHOOL_CHOICES = [
    ("FR", "Freshman"),
    ("SO", "Sophomore"),
    ("JR", "Junior"),
    ("SR", "Senior"),
    ("GR", "Graduate"),
]
```

Generally, it's best to define choices inside a model class, and to define a suitably-named constant for each value:

```
from django.db import models

class Student(models.Model):
    FRESHMAN = "FR"
    SOPHOMORE = "SO"
    JUNIOR = "JR"
    SENIOR = "SR"
    GRADUATE = "GR"
    YEAR_IN_SCHOOL_CHOICES = [
        (FRESHMAN, "Freshman"),
        (SOPHOMORE, "Sophomore"),
        (JUNIOR, "Junior"),
        (SENIOR, "Senior"),
        (GRADUATE, "Graduate"),
    ]
    year_in_school = models.CharField(
        max_length=2,
        choices=YEAR_IN_SCHOOL_CHOICES,
        default=FRESHMAN,
    )

    def is_upperclass(self):
```

(continues on next page)

(continued from previous page)

```
return self.year_in_school in {self.JUNIOR, self.SENIOR}
```

Though you can define a choices list outside of a model class and then refer to it, defining the choices and names for each choice inside the model class keeps all of that information with the class that uses it, and helps reference the choices (e.g. `Student.SOPHOMORE` will work anywhere that the `Student` model has been imported).

You can also collect your available choices into named groups that can be used for organizational purposes:

```
MEDIA_CHOICES = [
    (
        "Audio",
        (
            ("vinyl", "Vinyl"),
            ("cd", "CD"),
        ),
    ),
    (
        "Video",
        (
            ("vhs", "VHS Tape"),
            ("dvd", "DVD"),
        ),
    ),
    ("unknown", "Unknown"),
]
```

The first element in each tuple is the name to apply to the group. The second element is an iterable of 2-tuples, with each 2-tuple containing a value and a human-readable name for an option. Grouped options may be combined with ungrouped options within a single list (such as the 'unknown' option in this example).

For each model field that has `choices` set, Django will add a method to retrieve the human-readable name for the field's current value. See `get_FOO_display()` in the database API documentation.

Note that choices can be any sequence object –not necessarily a list or tuple. This lets you construct choices dynamically. But if you find yourself hacking `choices` to be dynamic, you're probably better off using a proper database table with a `ForeignKey`. `choices` is meant for static data that doesn't change much, if ever.

Note: A new migration is created each time the order of `choices` changes.

Unless `blank=False` is set on the field along with a `default` then a label containing "-----" will be rendered with the select box. To override this behavior, add a tuple to `choices` containing `None`; e.g. `(None,`

'Your String For Display'). Alternatively, you can use an empty string instead of `None` where this makes sense - such as on a [CharField](#).

Enumeration types

In addition, Django provides enumeration types that you can subclass to define choices in a concise way:

```
from django.utils.translation import gettext_lazy as _

class Student(models.Model):
    class YearInSchool(models.TextChoices):
        FRESHMAN = "FR", _("Freshman")
        SOPHOMORE = "SO", _("Sophomore")
        JUNIOR = "JR", _("Junior")
        SENIOR = "SR", _("Senior")
        GRADUATE = "GR", _("Graduate")

    year_in_school = models.CharField(
        max_length=2,
        choices=YearInSchool.choices,
        default=YearInSchool.FRESHMAN,
    )

    def is_upperclass(self):
        return self.year_in_school in {
            self.YearInSchool.JUNIOR,
            self.YearInSchool.SENIOR,
        }
```

These work similar to [enum](#) from Python's standard library, but with some modifications:

- Enum member values are a tuple of arguments to use when constructing the concrete data type. Django supports adding an extra string value to the end of this tuple to be used as the human-readable name, or label. The label can be a lazy translatable string. Thus, in most cases, the member value will be a (value, label) two-tuple. See below for [an example of subclassing choices](#) using a more complex data type. If a tuple is not provided, or the last item is not a (lazy) string, the label is [automatically generated](#) from the member name.
- A `.label` property is added on values, to return the human-readable name.
- A number of custom properties are added to the enumeration classes – `.choices`, `.labels`, `.values`, and `.names` – to make it easier to access lists of those separate parts of the enumeration. Use `.choices` as a suitable value to pass to [choices](#) in a field definition.

Warning: These property names cannot be used as member names as they would conflict.

- The use of `enum.unique()` is enforced to ensure that values cannot be defined multiple times. This is unlikely to be expected in choices for a field.

Note that using `YearInSchool.SENIOR`, `YearInSchool['SENIOR']`, or `YearInSchool('SR')` to access or lookup enum members work as expected, as do the `.name` and `.value` properties on the members.

If you don't need to have the human-readable names translated, you can have them inferred from the member name (replacing underscores with spaces and using title-case):

```
>>> class Vehicle(models.TextChoices):
...     CAR = "C"
...     TRUCK = "T"
...     JET_SKI = "J"
...
>>> Vehicle.JET_SKI.label
'Jet Ski'
```

Since the case where the enum values need to be integers is extremely common, Django provides an `IntegerChoices` class. For example:

```
class Card(models.Model):
    class Suit(models.IntegerChoices):
        DIAMOND = 1
        SPADE = 2
        HEART = 3
        CLUB = 4

    suit = models.IntegerField(choices=Suit.choices)
```

It is also possible to make use of the [Enum Functional API](#) with the caveat that labels are automatically generated as highlighted above:

```
>>> MedalType = models.TextChoices("MedalType", "GOLD SILVER BRONZE")
>>> MedalType.choices
[('GOLD', 'Gold'), ('SILVER', 'Silver'), ('BRONZE', 'Bronze')]
>>> Place = models.IntegerChoices("Place", "FIRST SECOND THIRD")
>>> Place.choices
[(1, 'First'), (2, 'Second'), (3, 'Third')]
```

If you require support for a concrete data type other than `int` or `str`, you can subclass `Choices` and the required concrete data type, e.g. `date` for use with `DateField`:

```
class MoonLandings(datetime.date, models.Choices):
    APOLLO_11 = 1969, 7, 20, "Apollo 11 (Eagle)"
    APOLLO_12 = 1969, 11, 19, "Apollo 12 (Intrepid)"
    APOLLO_14 = 1971, 2, 5, "Apollo 14 (Antares)"
    APOLLO_15 = 1971, 7, 30, "Apollo 15 (Falcon)"
    APOLLO_16 = 1972, 4, 21, "Apollo 16 (Orion)"
    APOLLO_17 = 1972, 12, 11, "Apollo 17 (Challenger)"
```

There are some additional caveats to be aware of:

- Enumeration types do not support `named groups`.
- Because an enumeration with a concrete data type requires all values to match the type, overriding the `blank label` cannot be achieved by creating a member with a value of `None`. Instead, set the `__empty__` attribute on the class:

```
class Answer(models.IntegerChoices):
    NO = 0, _("No")
    YES = 1, _("Yes")

    __empty__ = _("Unknown")
```

`db_column`

`Field.db_column`

The name of the database column to use for this field. If this isn't given, Django will use the field's name.

If your database column name is an SQL reserved word, or contains characters that aren't allowed in Python variable names—notably, the hyphen—that's OK. Django quotes column and table names behind the scenes.

`db_comment`

`Field.db_comment`

The comment on the database column to use for this field. It is useful for documenting fields for individuals with direct database access who may not be looking at your Django code. For example:

```
pub_date = models.DateTimeField(
    db_comment="Date and time when the article was published",
)
```

db_index

Field.db_index

If `True`, a database index will be created for this field.

Use the `indexes` option instead.

Where possible, use the *Meta.indexes* option instead. In nearly all cases, *indexes* provides more functionality than `db_index`. `db_index` may be deprecated in the future.

db_tablespace

Field.db_tablespace

The name of the *database tablespace* to use for this field's index, if this field is indexed. The default is the project's `DEFAULT_INDEX_TABLESPACE` setting, if set, or the *db_tablespace* of the model, if any. If the backend doesn't support tablespaces for indexes, this option is ignored.

default

Field.default

The default value for the field. This can be a value or a callable object. If callable it will be called every time a new object is created.

The default can't be a mutable object (model instance, `list`, `set`, etc.), as a reference to the same instance of that object would be used as the default value in all new model instances. Instead, wrap the desired default in a callable. For example, if you want to specify a default dict for *JSONField*, use a function:

```
def contact_default():
    return {"email": "to1@example.com"}

contact_info = JSONField("ContactInfo", default=contact_default)
```

lambdas can't be used for field options like `default` because they can't be *serialized by migrations*. See that documentation for other caveats.

For fields like *ForeignKey* that map to model instances, defaults should be the value of the field they reference (pk unless *to_field* is set) instead of model instances.

The default value is used when new model instances are created and a value isn't provided for the field. When the field is a primary key, the default is also used when the field is set to `None`.

`editable`

`Field.editable`

If `False`, the field will not be displayed in the admin or any other *ModelForm*. They are also skipped during *model validation*. Default is `True`.

`error_messages`

`Field.error_messages`

The `error_messages` argument lets you override the default messages that the field will raise. Pass in a dictionary with keys matching the error messages you want to override.

Error message keys include `null`, `blank`, `invalid`, `invalid_choice`, `unique`, and `unique_for_date`. Additional error message keys are specified for each field in the *Field types* section below.

These error messages often don't propagate to forms. See *Considerations regarding model's error_messages*.

`help_text`

`Field.help_text`

Extra “help” text to be displayed with the form widget. It's useful for documentation even if your field isn't used on a form.

Note that this value is not HTML-escaped in automatically-generated forms. This lets you include HTML in *help_text* if you so desire. For example:

```
help_text = "Please use the following format: <em>YYYY-MM-DD</em>."
```

Alternatively you can use plain text and `django.utils.html.escape()` to escape any HTML special characters. Ensure that you escape any help text that may come from untrusted users to avoid a cross-site scripting attack.

`primary_key`

`Field.primary_key`

If `True`, this field is the primary key for the model.

If you don't specify `primary_key=True` for any field in your model, Django will automatically add a field to hold the primary key, so you don't need to set `primary_key=True` on any of your fields unless you want to override the default primary-key behavior. The type of auto-created primary key fields can be specified

per app in `AppConfig.default_auto_field` or globally in the `DEFAULT_AUTO_FIELD` setting. For more, see [Automatic primary key fields](#).

`primary_key=True` implies `null=False` and `unique=True`. Only one primary key is allowed on an object.

The primary key field is read-only. If you change the value of the primary key on an existing object and then save it, a new object will be created alongside the old one.

The primary key field is set to `None` when *deleting* an object.

`unique`

`Field.unique`

If `True`, this field must be unique throughout the table.

This is enforced at the database level and by model validation. If you try to save a model with a duplicate value in a *unique* field, a `django.db.IntegrityError` will be raised by the model's `save()` method.

This option is valid on all field types except *ManyToManyField* and *OneToOneField*.

Note that when `unique` is `True`, you don't need to specify `db_index`, because `unique` implies the creation of an index.

`unique_for_date`

`Field.unique_for_date`

Set this to the name of a *DateField* or *DateTimeField* to require that this field be unique for the value of the date field.

For example, if you have a field `title` that has `unique_for_date="pub_date"`, then Django wouldn't allow the entry of two records with the same `title` and `pub_date`.

Note that if you set this to point to a *DateTimeField*, only the date portion of the field will be considered. Besides, when `USE_TZ` is `True`, the check will be performed in the *current time zone* at the time the object gets saved.

This is enforced by `Model.validate_unique()` during model validation but not at the database level. If any `unique_for_date` constraint involves fields that are not part of a *ModelForm* (for example, if one of the fields is listed in `exclude` or has `editable=False`), `Model.validate_unique()` will skip validation for that particular constraint.

`unique_for_month`

`Field.unique_for_month`

Like *unique_for_date*, but requires the field to be unique with respect to the month.

`unique_for_year`

`Field.unique_for_year`

Like *unique_for_date* and *unique_for_month*.

`verbose_name`

`Field.verbose_name`

A human-readable name for the field. If the verbose name isn't given, Django will automatically create it using the field's attribute name, converting underscores to spaces. See [Verbose field names](#).

`validators`

`Field.validators`

A list of validators to run for this field. See the [validators documentation](#) for more information.

Field types

`AutoField`

```
class AutoField(**options)
```

An *IntegerField* that automatically increments according to available IDs. You usually won't need to use this directly; a primary key field will automatically be added to your model if you don't specify otherwise. See [Automatic primary key fields](#).

`BigAutoField`

```
class BigAutoField(**options)
```

A 64-bit integer, much like an *AutoField* except that it is guaranteed to fit numbers from 1 to 9223372036854775807.

BigIntegerField

```
class BigIntegerField(**options)
```

A 64-bit integer, much like an *IntegerField* except that it is guaranteed to fit numbers from -9223372036854775808 to 9223372036854775807. The default form widget for this field is a *NumberInput*.

BinaryField

```
class BinaryField(max_length=None, **options)
```

A field to store raw binary data. It can be assigned *bytes*, *bytearray*, or *memoryview*.

By default, *BinaryField* sets *editable* to *False*, in which case it can't be included in a *ModelForm*.

BinaryField.max_length

Optional. The maximum length (in bytes) of the field. The maximum length is enforced in Django's validation using *MaxLengthValidator*.

Abusing BinaryField

Although you might think about storing files in the database, consider that it is bad design in 99% of the cases. This field is not a replacement for proper *static files* handling.

BooleanField

```
class BooleanField(**options)
```

A true/false field.

The default form widget for this field is *CheckboxInput*, or *NullBooleanSelect* if *null=True*.

The default value of *BooleanField* is *None* when *Field.default* isn't defined.

CharField

```
class CharField(max_length=None, **options)
```

A string field, for small- to large-sized strings.

For large amounts of text, use *TextField*.

The default form widget for this field is a *TextInput*.

CharField has the following extra arguments:

CharField.max_length

The maximum length (in characters) of the field. The `max_length` is enforced at the database level and in Django’s validation using *MaxLengthValidator*. It’s required for all database backends included with Django except PostgreSQL, which supports unlimited VARCHAR columns.

Note: If you are writing an application that must be portable to multiple database backends, you should be aware that there are restrictions on `max_length` for some backends. Refer to the [database backend notes](#) for details.

Support for unlimited VARCHAR columns was added on PostgreSQL.

CharField.db_collation

Optional. The database collation name of the field.

Note: Collation names are not standardized. As such, this will not be portable across multiple database backends.

Oracle

Oracle supports collations only when the `MAX_STRING_SIZE` database initialization parameter is set to `EXTENDED`.

DateField

```
class DateField(auto_now=False, auto_now_add=False, **options)
```

A date, represented in Python by a `datetime.date` instance. Has a few extra, optional arguments:

DateField.auto_now

Automatically set the field to now every time the object is saved. Useful for “last-modified” timestamps. Note that the current date is always used; it’s not just a default value that you can override.

The field is only automatically updated when calling *Model.save()*. The field isn’t updated when making updates to other fields in other ways such as *QuerySet.update()*, though you can specify a custom value for the field in an update like that.

DateField.auto_now_add

Automatically set the field to now when the object is first created. Useful for creation of timestamps. Note that the current date is always used; it’s not just a default value that you can override. So even if you set a value for this field when creating the object, it will be ignored. If you want to be able to modify this field, set the following instead of `auto_now_add=True`:

- For *DateField*: `default=date.today` - from `datetime.date.today()`
- For *DateTimeField*: `default=timezone.now` - from `django.utils.timezone.now()`

The default form widget for this field is a *DateInput*. The admin adds a JavaScript calendar, and a shortcut for “Today” . Includes an additional `invalid_date` error message key.

The options `auto_now_add`, `auto_now`, and `default` are mutually exclusive. Any combination of these options will result in an error.

Note: As currently implemented, setting `auto_now` or `auto_now_add` to `True` will cause the field to have `editable=False` and `blank=True` set.

Note: The `auto_now` and `auto_now_add` options will always use the date in the `default timezone` at the moment of creation or update. If you need something different, you may want to consider using your own callable default or overriding `save()` instead of using `auto_now` or `auto_now_add`; or using a *DateTimeField* instead of a *DateField* and deciding how to handle the conversion from `datetime` to `date` at display time.

DateTimeField

```
class DateTimeField(auto_now=False, auto_now_add=False, **options)
```

A date and time, represented in Python by a `datetime.datetime` instance. Takes the same extra arguments as *DateField*.

The default form widget for this field is a single *DateTimeInput*. The admin uses two separate *TextInput* widgets with JavaScript shortcuts.

DecimalField

```
class DecimalField(max_digits=None, decimal_places=None, **options)
```

A fixed-precision decimal number, represented in Python by a `Decimal` instance. It validates the input using *DecimalValidator*.

Has the following required arguments:

`DecimalField.max_digits`

The maximum number of digits allowed in the number. Note that this number must be greater than or equal to `decimal_places`.

`DecimalField.decimal_places`

The number of decimal places to store with the number.

For example, to store numbers up to 999.99 with a resolution of 2 decimal places, you'd use:

```
models.DecimalField(..., max_digits=5, decimal_places=2)
```

And to store numbers up to approximately one billion with a resolution of 10 decimal places:

```
models.DecimalField(..., max_digits=19, decimal_places=10)
```

The default form widget for this field is a *NumberInput* when *localize* is *False* or *TextInput* otherwise.

Note: For more information about the differences between the *FloatField* and *DecimalField* classes, please see [FloatField vs. DecimalField](#). You should also be aware of [SQLite limitations](#) of decimal fields.

DurationField

```
class DurationField(**options)
```

A field for storing periods of time - modeled in Python by *timedelta*. When used on PostgreSQL, the data type used is an *interval* and on Oracle the data type is *INTERVAL DAY(9) TO SECOND(6)*. Otherwise a *bigint* of microseconds is used.

Note: Arithmetic with *DurationField* works in most cases. However on all databases other than PostgreSQL, comparing the value of a *DurationField* to arithmetic on *DateTimeField* instances will not work as expected.

EmailField

```
class EmailField(max_length=254, **options)
```

A *CharField* that checks that the value is a valid email address using *EmailValidator*.

FileField

```
class FileField(upload_to='', storage=None, max_length=100, **options)
```

A file-upload field.

Note: The *primary_key* argument isn't supported and will raise an error if used.

Has the following optional arguments:

FileField.upload_to

This attribute provides a way of setting the upload directory and file name, and can be set in two ways. In both cases, the value is passed to the `Storage.save()` method.

If you specify a string value or a `Path`, it may contain `strftime()` formatting, which will be replaced by the date/time of the file upload (so that uploaded files don't fill up the given directory). For example:

```
class MyModel(models.Model):
    # file will be uploaded to MEDIA_ROOT/uploads
    upload = models.FileField(upload_to="uploads/")
    # or...
    # file will be saved to MEDIA_ROOT/uploads/2015/01/30
    upload = models.FileField(upload_to="uploads/%Y/%m/%d/")
```

If you are using the default `FileSystemStorage`, the string value will be appended to your `MEDIA_ROOT` path to form the location on the local filesystem where uploaded files will be stored. If you are using a different storage, check that storage's documentation to see how it handles `upload_to`.

`upload_to` may also be a callable, such as a function. This will be called to obtain the upload path, including the filename. This callable must accept two arguments and return a Unix-style path (with forward slashes) to be passed along to the storage system. The two arguments are:

Argument	Description
<code>instance</code>	An instance of the model where the <code>FileField</code> is defined. More specifically, this is the particular instance where the current file is being attached. In most cases, this object will not have been saved to the database yet, so if it uses the default <code>AutoField</code> , it might not yet have a value for its primary key field.
<code>file</code>	The filename that was originally given to the file. This may or may not be taken into account when determining the final destination path.

For example:

```
def user_directory_path(instance, filename):
    # file will be uploaded to MEDIA_ROOT/user_<id>/<filename>
    return "user_{0}/{1}".format(instance.user.id, filename)

class MyModel(models.Model):
    upload = models.FileField(upload_to=user_directory_path)
```

FileField.storage

A storage object, or a callable which returns a storage object. This handles the storage and retrieval of

your files. See [Managing files](#) for details on how to provide this object.

The default form widget for this field is a [ClearableFileInput](#).

Using a [FileField](#) or an [ImageField](#) (see below) in a model takes a few steps:

1. In your settings file, you'll need to define [MEDIA_ROOT](#) as the full path to a directory where you'd like Django to store uploaded files. (For performance, these files are not stored in the database.) Define [MEDIA_URL](#) as the base public URL of that directory. Make sure that this directory is writable by the web server's user account.
2. Add the [FileField](#) or [ImageField](#) to your model, defining the [upload_to](#) option to specify a subdirectory of [MEDIA_ROOT](#) to use for uploaded files.
3. All that will be stored in your database is a path to the file (relative to [MEDIA_ROOT](#)). You'll most likely want to use the convenience [url](#) attribute provided by Django. For example, if your [ImageField](#) is called `mug_shot`, you can get the absolute path to your image in a template with `{{ object.mug_shot.url }}`.

For example, say your [MEDIA_ROOT](#) is set to `'/home/media'`, and [upload_to](#) is set to `'photos/%Y/%m/%d'`. The `'%Y/%m/%d'` part of [upload_to](#) is `strftime()` formatting; `'%Y'` is the four-digit year, `'%m'` is the two-digit month and `'%d'` is the two-digit day. If you upload a file on Jan. 15, 2007, it will be saved in the directory `/home/media/photos/2007/01/15`.

If you wanted to retrieve the uploaded file's on-disk filename, or the file's size, you could use the [name](#) and [size](#) attributes respectively; for more information on the available attributes and methods, see the [File](#) class reference and the [Managing files](#) topic guide.

Note: The file is saved as part of saving the model in the database, so the actual file name used on disk cannot be relied on until after the model has been saved.

The uploaded file's relative URL can be obtained using the [url](#) attribute. Internally, this calls the [url\(\)](#) method of the underlying [Storage](#) class.

Note that whenever you deal with uploaded files, you should pay close attention to where you're uploading them and what type of files they are, to avoid security holes. Validate all uploaded files so that you're sure the files are what you think they are. For example, if you blindly let somebody upload files, without validation, to a directory that's within your web server's document root, then somebody could upload a CGI or PHP script and execute that script by visiting its URL on your site. Don't allow that.

Also note that even an uploaded HTML file, since it can be executed by the browser (though not by the server), can pose security threats that are equivalent to XSS or CSRF attacks.

[FileField](#) instances are created in your database as `varchar` columns with a default max length of 100 characters. As with other fields, you can change the maximum length using the [max_length](#) argument.

FileField and FieldFile

class FieldFile

When you access a *FileField* on a model, you are given an instance of *FieldFile* as a proxy for accessing the underlying file.

The API of *FieldFile* mirrors that of *File*, with one key difference: The object wrapped by the class is not necessarily a wrapper around Python's built-in file object. Instead, it is a wrapper around the result of the *Storage.open()* method, which may be a *File* object, or it may be a custom storage's implementation of the *File* API.

In addition to the API inherited from *File* such as *read()* and *write()*, *FieldFile* includes several methods that can be used to interact with the underlying file:

Warning: Two methods of this class, *save()* and *delete()*, default to saving the model object of the associated *FieldFile* in the database.

FieldFile.name

The name of the file including the relative path from the root of the *Storage* of the associated *FileField*.

FieldFile.path

A read-only property to access the file's local filesystem path by calling the *path()* method of the underlying *Storage* class.

FieldFile.size

The result of the underlying *Storage.size()* method.

FieldFile.url

A read-only property to access the file's relative URL by calling the *url()* method of the underlying *Storage* class.

FieldFile.open(mode='rb')

Opens or reopens the file associated with this instance in the specified *mode*. Unlike the standard Python *open()* method, it doesn't return a file descriptor.

Since the underlying file is opened implicitly when accessing it, it may be unnecessary to call this method except to reset the pointer to the underlying file or to change the *mode*.

FieldFile.close()

Behaves like the standard Python *file.close()* method and closes the file associated with this instance.

`FieldFile.save(name, content, save=True)`

This method takes a filename and file contents and passes them to the storage class for the field, then associates the stored file with the model field. If you want to manually associate file data with *FileField* instances on your model, the `save()` method is used to persist that file data.

Takes two required arguments: `name` which is the name of the file, and `content` which is an object containing the file's contents. The optional `save` argument controls whether or not the model instance is saved after the file associated with this field has been altered. Defaults to `True`.

Note that the `content` argument should be an instance of *django.core.files.File*, not Python's built-in file object. You can construct a *File* from an existing Python file object like this:

```
from django.core.files import File

# Open an existing file using Python's built-in open()
f = open("/path/to/hello.world")
myfile = File(f)
```

Or you can construct one from a Python string like this:

```
from django.core.files.base import ContentFile

myfile = ContentFile("hello world")
```

For more information, see [Managing files](#).

`FieldFile.delete(save=True)`

Deletes the file associated with this instance and clears all attributes on the field. Note: This method will close the file if it happens to be open when `delete()` is called.

The optional `save` argument controls whether or not the model instance is saved after the file associated with this field has been deleted. Defaults to `True`.

Note that when a model is deleted, related files are not deleted. If you need to cleanup orphaned files, you'll need to handle it yourself (for instance, with a custom management command that can be run manually or scheduled to run periodically via e.g. cron).

FilePathField

```
class FilePathField(path="", match=None, recursive=False, allow_files=True, allow_folders=False,
                    max_length=100, **options)
```

A *CharField* whose choices are limited to the filenames in a certain directory on the filesystem. Has some special arguments, of which the first is required:

FilePathField.path

Required. The absolute filesystem path to a directory from which this *FilePathField* should get its choices. Example: `"/home/images"`.

`path` may also be a callable, such as a function to dynamically set the path at runtime. Example:

```
import os
from django.conf import settings
from django.db import models

def images_path():
    return os.path.join(settings.LOCAL_FILE_DIR, "images")

class MyModel(models.Model):
    file = models.FilePathField(path=images_path)
```

FilePathField.match

Optional. A regular expression, as a string, that *FilePathField* will use to filter filenames. Note that the regex will be applied to the base filename, not the full path. Example: `"foo.*\.txt$"`, which will match a file called `foo23.txt` but not `bar.txt` or `foo23.png`.

FilePathField.recursive

Optional. Either `True` or `False`. Default is `False`. Specifies whether all subdirectories of *path* should be included

FilePathField.allow_files

Optional. Either `True` or `False`. Default is `True`. Specifies whether files in the specified location should be included. Either this or *allow_folders* must be `True`.

FilePathField.allow_folders

Optional. Either `True` or `False`. Default is `False`. Specifies whether folders in the specified location should be included. Either this or *allow_files* must be `True`.

The one potential gotcha is that *match* applies to the base filename, not the full path. So, this example:

```
FilePathField(path="/home/images", match="foo.*", recursive=True)
```

...will match `/home/images/foo.png` but not `/home/images/foo/bar.png` because the *match* applies to the base filename (`foo.png` and `bar.png`).

FilePathField instances are created in your database as `varchar` columns with a default max length of 100 characters. As with other fields, you can change the maximum length using the *max_length* argument.

FloatField

```
class FloatField(**options)
```

A floating-point number represented in Python by a `float` instance.

The default form widget for this field is a *NumberInput* when *localize* is `False` or *TextInput* otherwise.

FloatField vs. DecimalField

The *FloatField* class is sometimes mixed up with the *DecimalField* class. Although they both represent real numbers, they represent those numbers differently. *FloatField* uses Python's `float` type internally, while *DecimalField* uses Python's `Decimal` type. For information on the difference between the two, see Python's documentation for the `decimal` module.

GenericIPAddressField

```
class GenericIPAddressField(protocol='both', unpack_ipv4=False, **options)
```

An IPv4 or IPv6 address, in string format (e.g. `192.0.2.30` or `2a02:42fe::4`). The default form widget for this field is a *TextInput*.

The IPv6 address normalization follows [RFC 4291#section-2.2](#) section 2.2, including using the IPv4 format suggested in paragraph 3 of that section, like `::ffff:192.0.2.0`. For example, `2001:0::0:01` would be normalized to `2001::1`, and `::ffff:0a0a:0a0a` to `::ffff:10.10.10.10`. All characters are converted to lowercase.

GenericIPAddressField.protocol

Limits valid inputs to the specified protocol. Accepted values are `'both'` (default), `'IPv4'` or `'IPv6'`. Matching is case insensitive.

GenericIPAddressField.unpack_ipv4

Unpacks IPv4 mapped addresses like `::ffff:192.0.2.1`. If this option is enabled that address would be unpacked to `192.0.2.1`. Default is disabled. Can only be used when `protocol` is set to `'both'`.

If you allow for blank values, you have to allow for null values since blank values are stored as null.

ImageField

```
class ImageField(upload_to=None, height_field=None, width_field=None, max_length=100, **options)
```

Inherits all attributes and methods from *FileField*, but also validates that the uploaded object is a valid image.

In addition to the special attributes that are available for *FileField*, an *ImageField* also has `height` and `width` attributes.

To facilitate querying on those attributes, *ImageField* has the following optional arguments:

`ImageField.height_field`

Name of a model field which will be auto-populated with the height of the image each time the model instance is saved.

`ImageField.width_field`

Name of a model field which will be auto-populated with the width of the image each time the model instance is saved.

Requires the *Pillow* library.

ImageField instances are created in your database as `varchar` columns with a default max length of 100 characters. As with other fields, you can change the maximum length using the `max_length` argument.

The default form widget for this field is a *ClearableFileInput*.

IntegerField

```
class IntegerField(**options)
```

An integer. Values from -2147483648 to 2147483647 are safe in all databases supported by Django.

It uses *MinValueValidator* and *MaxValueValidator* to validate the input based on the values that the default database supports.

The default form widget for this field is a *NumberInput* when `localize` is `False` or *TextInput* otherwise.

JSONField

```
class JSONField(encoder=None, decoder=None, **options)
```

A field for storing JSON encoded data. In Python the data is represented in its Python native format: dictionaries, lists, strings, numbers, booleans and `None`.

JSONField is supported on MariaDB, MySQL, Oracle, PostgreSQL, and SQLite (with the *JSON1 extension enabled*).

JSONField.encoder

An optional `json.JSONEncoder` subclass to serialize data types not supported by the standard JSON serializer (e.g. `datetime.datetime` or `UUID`). For example, you can use the *DjangoJSONEncoder* class.

Defaults to `json.JSONEncoder`.

JSONField.decoder

An optional `json.JSONDecoder` subclass to deserialize the value retrieved from the database. The value will be in the format chosen by the custom encoder (most often a string). Your deserialization may need to account for the fact that you can't be certain of the input type. For example, you run the risk of returning a `datetime` that was actually a string that just happened to be in the same format chosen for `datetimes`.

Defaults to `json.JSONDecoder`.

To query `JSONField` in the database, see [Querying JSONField](#).

Default value

If you give the field a *default*, ensure it's a callable such as the `dict` class or a function that returns a fresh object each time. Incorrectly using a mutable object like `default={}` or `default=[]` creates a mutable default that is shared between all instances.

Indexing

Index and *Field.db_index* both create a B-tree index, which isn't particularly helpful when querying `JSONField`. On PostgreSQL only, you can use *GinIndex* that is better suited.

PostgreSQL users

PostgreSQL has two native JSON based data types: `json` and `jsonb`. The main difference between them is how they are stored and how they can be queried. PostgreSQL's `json` field is stored as the original string representation of the JSON and must be decoded on the fly when queried based on keys. The `jsonb` field is stored based on the actual structure of the JSON which allows indexing. The trade-off is a small additional cost on writing to the `jsonb` field. `JSONField` uses `jsonb`.

Oracle users

Oracle Database does not support storing JSON scalar values. Only JSON objects and arrays (represented in Python using `dict` and `list`) are supported.

PositiveBigIntegerField

```
class PositiveBigIntegerField(**options)
```

Like a *PositiveIntegerField*, but only allows values under a certain (database-dependent) point. Values from 0 to 9223372036854775807 are safe in all databases supported by Django.

PositiveIntegerField

```
class PositiveIntegerField(**options)
```

Like an *IntegerField*, but must be either positive or zero (0). Values from 0 to 2147483647 are safe in all databases supported by Django. The value 0 is accepted for backward compatibility reasons.

PositiveSmallIntegerField

```
class PositiveSmallIntegerField(**options)
```

Like a *PositiveIntegerField*, but only allows values under a certain (database-dependent) point. Values from 0 to 32767 are safe in all databases supported by Django.

SlugField

```
class SlugField(max_length=50, **options)
```

Slug is a newspaper term. A slug is a short label for something, containing only letters, numbers, underscores or hyphens. They're generally used in URLs.

Like a *CharField*, you can specify *max_length* (read the note about database portability and *max_length* in that section, too). If *max_length* is not specified, Django will use a default length of 50.

Implies setting *Field.db_index* to True.

It is often useful to automatically prepopulate a *SlugField* based on the value of some other value. You can do this automatically in the admin using *prepopulated_fields*.

It uses *validate_slug* or *validate_unicode_slug* for validation.

SlugField.allow_unicode

If True, the field accepts Unicode letters in addition to ASCII letters. Defaults to False.

SmallAutoField

```
class SmallAutoField(**options)
```

Like an *AutoField*, but only allows values under a certain (database-dependent) limit. Values from 1 to 32767 are safe in all databases supported by Django.

SmallIntegerField

```
class SmallIntegerField(**options)
```

Like an *IntegerField*, but only allows values under a certain (database-dependent) point. Values from -32768 to 32767 are safe in all databases supported by Django.

TextField

```
class TextField(**options)
```

A large text field. The default form widget for this field is a *Textarea*.

If you specify a `max_length` attribute, it will be reflected in the *Textarea* widget of the auto-generated form field. However it is not enforced at the model or database level. Use a *CharField* for that.

TextField.db_collation

Optional. The database collation name of the field.

Note: Collation names are not standardized. As such, this will not be portable across multiple database backends.

Oracle

Oracle does not support collations for a *TextField*.

TimeField

```
class TimeField(auto_now=False, auto_now_add=False, **options)
```

A time, represented in Python by a `datetime.time` instance. Accepts the same auto-population options as *DateTimeField*.

The default form widget for this field is a *TimeInput*. The admin adds some JavaScript shortcuts.

URLField

```
class URLField(max_length=200, **options)
```

A *CharField* for a URL, validated by *URLValidator*.

The default form widget for this field is a *URLInput*.

Like all *CharField* subclasses, *URLField* takes the optional *max_length* argument. If you don't specify *max_length*, a default of 200 is used.

UUIDField

```
class UUIDField(**options)
```

A field for storing universally unique identifiers. Uses Python's *UUID* class. When used on PostgreSQL, this stores in a *uuid* datatype, otherwise in a *char(32)*.

Universally unique identifiers are a good alternative to *AutoField* for *primary_key*. The database will not generate the UUID for you, so it is recommended to use *default*:

```
import uuid
from django.db import models

class MyUUIDModel(models.Model):
    id = models.UUIDField(primary_key=True, default=uuid.uuid4, editable=False)
    # other fields
```

Note that a callable (with the parentheses omitted) is passed to *default*, not an instance of *UUID*.

Lookups on PostgreSQL

Using *exact*, *contains*, *icontains*, *startswith*, *istartswith*, *endswith*, or *iendswith* lookups on PostgreSQL don't work for values without hyphens, because PostgreSQL stores them in a hyphenated *uuid* datatype type.

Relationship fields

Django also defines a set of fields that represent relations.

ForeignKey

```
class ForeignKey(to, on_delete, **options)
```

A many-to-one relationship. Requires two positional arguments: the class to which the model is related and the `on_delete` option.

To create a recursive relationship –an object that has a many-to-one relationship with itself –use `models.ForeignKey('self', on_delete=models.CASCADE)`.

If you need to create a relationship on a model that has not yet been defined, you can use the name of the model, rather than the model object itself:

```
from django.db import models

class Car(models.Model):
    manufacturer = models.ForeignKey(
        "Manufacturer",
        on_delete=models.CASCADE,
    )
    # ...

class Manufacturer(models.Model):
    # ...
    pass
```

Relationships defined this way on [abstract models](#) are resolved when the model is subclassed as a concrete model and are not relative to the abstract model's `app_label`:

Listing 11: `products/models.py`

```
from django.db import models

class AbstractCar(models.Model):
    manufacturer = models.ForeignKey("Manufacturer", on_delete=models.CASCADE)

    class Meta:
        abstract = True
```

Listing 12: production/models.py

```
from django.db import models
from products.models import AbstractCar

class Manufacturer(models.Model):
    pass

class Car(AbstractCar):
    pass

# Car.manufacturer will point to `production.Manufacturer` here.
```

To refer to models defined in another application, you can explicitly specify a model with the full application label. For example, if the `Manufacturer` model above is defined in another application called `production`, you'd need to use:

```
class Car(models.Model):
    manufacturer = models.ForeignKey(
        "production.Manufacturer",
        on_delete=models.CASCADE,
    )
```

This sort of reference, called a lazy relationship, can be useful when resolving circular import dependencies between two applications.

A database index is automatically created on the `ForeignKey`. You can disable this by setting `db_index` to `False`. You may want to avoid the overhead of an index if you are creating a foreign key for consistency rather than joins, or if you will be creating an alternative index like a partial or multiple column index.

Database Representation

Behind the scenes, Django appends "_id" to the field name to create its database column name. In the above example, the database table for the `Car` model will have a `manufacturer_id` column. (You can change this explicitly by specifying `db_column`) However, your code should never have to deal with the database column name, unless you write custom SQL. You'll always deal with the field names of your model object.

Arguments

`ForeignKey` accepts other arguments that define the details of how the relation works.

`ForeignKey.on_delete`

When an object referenced by a `ForeignKey` is deleted, Django will emulate the behavior of the SQL constraint specified by the `on_delete` argument. For example, if you have a nullable `ForeignKey` and you want it to be set null when the referenced object is deleted:

```
user = models.ForeignKey(
    User,
    models.SET_NULL,
    blank=True,
    null=True,
)
```

`on_delete` doesn't create an SQL constraint in the database. Support for database-level cascade options may be implemented later.

The possible values for `on_delete` are found in `django.db.models`:

- **CASCADE**

Cascade deletes. Django emulates the behavior of the SQL constraint ON DELETE CASCADE and also deletes the object containing the `ForeignKey`.

`Model.delete()` isn't called on related models, but the `pre_delete` and `post_delete` signals are sent for all deleted objects.

- **PROTECT**

Prevent deletion of the referenced object by raising `ProtectedError`, a subclass of `django.db.IntegrityError`.

- **RESTRICT**

Prevent deletion of the referenced object by raising `RestrictedError` (a subclass of `django.db.IntegrityError`). Unlike `PROTECT`, deletion of the referenced object is allowed if it also references a different object that is being deleted in the same operation, but via a `CASCADE` relationship.

Consider this set of models:

```
class Artist(models.Model):
    name = models.CharField(max_length=10)

class Album(models.Model):
    artist = models.ForeignKey(Artist, on_delete=models.CASCADE)

class Song(models.Model):
    artist = models.ForeignKey(Artist, on_delete=models.CASCADE)
    album = models.ForeignKey(Album, on_delete=models.RESTRICT)
```

Artist can be deleted even if that implies deleting an Album which is referenced by a Song, because Song also references Artist itself through a cascading relationship. For example:

```
>>> artist_one = Artist.objects.create(name="artist one")
>>> artist_two = Artist.objects.create(name="artist two")
>>> album_one = Album.objects.create(artist=artist_one)
>>> album_two = Album.objects.create(artist=artist_two)
>>> song_one = Song.objects.create(artist=artist_one, album=album_one)
>>> song_two = Song.objects.create(artist=artist_one, album=album_two)
>>> album_one.delete()
# Raises RestrictedError.
>>> artist_two.delete()
# Raises RestrictedError.
>>> artist_one.delete()
(4, {'Song': 2, 'Album': 1, 'Artist': 1})
```

- **SET_NULL**

Set the *ForeignKey* null; this is only possible if *null* is True.

- **SET_DEFAULT**

Set the *ForeignKey* to its default value; a default for the *ForeignKey* must be set.

- **SET()**

Set the *ForeignKey* to the value passed to *SET()*, or if a callable is passed in, the result of calling it. In most cases, passing a callable will be necessary to avoid executing queries at the time your `models.py` is imported:

```
from django.conf import settings
from django.contrib.auth import get_user_model
from django.db import models
```

(continues on next page)

(continued from previous page)

```
def get_sentinel_user():
    return get_user_model().objects.get_or_create(username="deleted")[0]

class MyModel(models.Model):
    user = models.ForeignKey(
        settings.AUTH_USER_MODEL,
        on_delete=models.SET(get_sentinel_user),
    )
```

- **DO_NOTHING**

Take no action. If your database backend enforces referential integrity, this will cause an *IntegrityError* unless you manually add an SQL `ON DELETE` constraint to the database field.

`ForeignKey.limit_choices_to`

Sets a limit to the available choices for this field when this field is rendered using a `ModelForm` or the admin (by default, all objects in the queryset are available to choose). Either a dictionary, a *Q* object, or a callable returning a dictionary or *Q* object can be used.

For example:

```
staff_member = models.ForeignKey(
    User,
    on_delete=models.CASCADE,
    limit_choices_to={"is_staff": True},
)
```

causes the corresponding field on the `ModelForm` to list only `Users` that have `is_staff=True`. This may be helpful in the Django admin.

The callable form can be helpful, for instance, when used in conjunction with the Python `datetime` module to limit selections by date range. For example:

```
def limit_pub_date_choices():
    return {"pub_date__lte": datetime.date.today()}

limit_choices_to = limit_pub_date_choices
```

If `limit_choices_to` is or returns a *Q object*, which is useful for *complex queries*, then it will only have an effect on the choices available in the admin when the field is not listed in *raw_id_fields* in the `ModelAdmin` for the model.

Note: If a callable is used for `limit_choices_to`, it will be invoked every time a new form is instan-

tiated. It may also be invoked when a model is validated, for example by management commands or the admin. The admin constructs querysets to validate its form inputs in various edge cases multiple times, so there is a possibility your callable may be invoked several times.

`ForeignKey.related_name`

The name to use for the relation from the related object back to this one. It's also the default value for `related_query_name` (the name to use for the reverse filter name from the target model). See the [related objects documentation](#) for a full explanation and example. Note that you must set this value when defining relations on [abstract models](#); and when you do so [some special syntax](#) is available.

If you'd prefer Django not to create a backwards relation, set `related_name` to '+' or end it with '+'. For example, this will ensure that the `User` model won't have a backwards relation to this model:

```
user = models.ForeignKey(
    User,
    on_delete=models.CASCADE,
    related_name="+",
)
```

`ForeignKey.related_query_name`

The name to use for the reverse filter name from the target model. It defaults to the value of `related_name` or `default_related_name` if set, otherwise it defaults to the name of the model:

```
# Declare the ForeignKey with related_query_name
class Tag(models.Model):
    article = models.ForeignKey(
        Article,
        on_delete=models.CASCADE,
        related_name="tags",
        related_query_name="tag",
    )
    name = models.CharField(max_length=255)

# That's now the name of the reverse filter
Article.objects.filter(tag__name="important")
```

Like `related_name`, `related_query_name` supports app label and class interpolation via [some special syntax](#).

`ForeignKey.to_field`

The field on the related object that the relation is to. By default, Django uses the primary key of the related object. If you reference a different field, that field must have `unique=True`.

`ForeignKey.db_constraint`

Controls whether or not a constraint should be created in the database for this foreign key. The default is `True`, and that's almost certainly what you want; setting this to `False` can be very bad for data integrity. That said, here are some scenarios where you might want to do this:

- You have legacy data that is not valid.
- You're sharding your database.

If this is set to `False`, accessing a related object that doesn't exist will raise its `DoesNotExist` exception.

`ForeignKey.swappable`

Controls the migration framework's reaction if this *ForeignKey* is pointing at a swappable model. If it is `True` - the default - then if the *ForeignKey* is pointing at a model which matches the current value of `settings.AUTH_USER_MODEL` (or another swappable model setting) the relationship will be stored in the migration using a reference to the setting, not to the model directly.

You only want to override this to be `False` if you are sure your model should always point toward the swapped-in model - for example, if it is a profile model designed specifically for your custom user model.

Setting it to `False` does not mean you can reference a swappable model even if it is swapped out - `False` means that the migrations made with this *ForeignKey* will always reference the exact model you specify (so it will fail hard if the user tries to run with a *User* model you don't support, for example).

If in doubt, leave it to its default of `True`.

ManyToManyField

```
class ManyToManyField(to, **options)
```

A many-to-many relationship. Requires a positional argument: the class to which the model is related, which works exactly the same as it does for *ForeignKey*, including *recursive* and *lazy* relationships.

Related objects can be added, removed, or created with the field's *RelatedManager*.

Database Representation

Behind the scenes, Django creates an intermediary join table to represent the many-to-many relationship. By default, this table name is generated using the name of the many-to-many field and the name of the table for the model that contains it. Since some databases don't support table names above a certain length, these table names will be automatically truncated and a uniqueness hash will be used, e.g. `author_books_9cdf`. You can manually provide the name of the join table using the *db_table* option.

Arguments

ManyToManyField accepts an extra set of arguments –all optional –that control how the relationship functions.

`ManyToManyField.related_name`

Same as *ForeignKey.related_name*.

`ManyToManyField.related_query_name`

Same as *ForeignKey.related_query_name*.

`ManyToManyField.limit_choices_to`

Same as *ForeignKey.limit_choices_to*.

`ManyToManyField.symmetrical`

Only used in the definition of `ManyToManyFields` on self. Consider the following model:

```
from django.db import models

class Person(models.Model):
    friends = models.ManyToManyField("self")
```

When Django processes this model, it identifies that it has a *ManyToManyField* on itself, and as a result, it doesn't add a `person_set` attribute to the `Person` class. Instead, the *ManyToManyField* is assumed to be symmetrical –that is, if I am your friend, then you are my friend.

If you do not want symmetry in many-to-many relationships with `self`, set *symmetrical* to `False`. This will force Django to add the descriptor for the reverse relationship, allowing *ManyToManyField* relationships to be non-symmetrical.

`ManyToManyField.through`

Django will automatically generate a table to manage many-to-many relationships. However, if you want to manually specify the intermediary table, you can use the *through* option to specify the Django model that represents the intermediate table that you want to use.

The most common use for this option is when you want to associate *extra data with a many-to-many relationship*.

Note: If you don't want multiple associations between the same instances, add a *UniqueConstraint* including the from and to fields. Django's automatically generated many-to-many tables include such a constraint.

Note: Recursive relationships using an intermediary model can't determine the reverse accessors

names, as they would be the same. You need to set a *related_name* to at least one of them. If you'd prefer Django not to create a backwards relation, set *related_name* to '+'.

If you don't specify an explicit *through* model, there is still an implicit *through* model class you can use to directly access the table created to hold the association. It has three fields to link the models.

If the source and target models differ, the following fields are generated:

- *id*: the primary key of the relation.
- *<containing_model>_id*: the id of the model that declares the *ManyToManyField*.
- *<other_model>_id*: the id of the model that the *ManyToManyField* points to.

If the *ManyToManyField* points from and to the same model, the following fields are generated:

- *id*: the primary key of the relation.
- *from_<model>_id*: the id of the instance which points at the model (i.e. the source instance).
- *to_<model>_id*: the id of the instance to which the relationship points (i.e. the target model instance).

This class can be used to query associated records for a given model instance like a normal model:

```
Model.m2mfield.through.objects.all()
```

ManyToManyField.through_fields

Only used when a custom intermediary model is specified. Django will normally determine which fields of the intermediary model to use in order to establish a many-to-many relationship automatically. However, consider the following models:

```
from django.db import models

class Person(models.Model):
    name = models.CharField(max_length=50)

class Group(models.Model):
    name = models.CharField(max_length=128)
    members = models.ManyToManyField(
        Person,
        through="Membership",
        through_fields=("group", "person"),
    )
```

(continues on next page)

(continued from previous page)

```
class Membership(models.Model):
    group = models.ForeignKey(Group, on_delete=models.CASCADE)
    person = models.ForeignKey(Person, on_delete=models.CASCADE)
    inviter = models.ForeignKey(
        Person,
        on_delete=models.CASCADE,
        related_name="membership_invites",
    )
    invite_reason = models.CharField(max_length=64)
```

Membership has two foreign keys to Person (person and inviter), which makes the relationship ambiguous and Django can't know which one to use. In this case, you must explicitly specify which foreign keys Django should use using `through_fields`, as in the example above.

`through_fields` accepts a 2-tuple ('field1', 'field2'), where `field1` is the name of the foreign key to the model the *ManyToManyField* is defined on (group in this case), and `field2` the name of the foreign key to the target model (person in this case).

When you have more than one foreign key on an intermediary model to any (or even both) of the models participating in a many-to-many relationship, you must specify `through_fields`. This also applies to *recursive relationships* when an intermediary model is used and there are more than two foreign keys to the model, or you want to explicitly specify which two Django should use.

ManyToManyField.db_table

The name of the table to create for storing the many-to-many data. If this is not provided, Django will assume a default name based upon the names of: the table for the model defining the relationship and the name of the field itself.

ManyToManyField.db_constraint

Controls whether or not constraints should be created in the database for the foreign keys in the intermediary table. The default is `True`, and that's almost certainly what you want; setting this to `False` can be very bad for data integrity. That said, here are some scenarios where you might want to do this:

- You have legacy data that is not valid.
- You're sharding your database.

It is an error to pass both `db_constraint` and `through`.

ManyToManyField.swappable

Controls the migration framework's reaction if this *ManyToManyField* is pointing at a swappable model. If it is `True` - the default - then if the *ManyToManyField* is pointing at a model which matches the current value of `settings.AUTH_USER_MODEL` (or another swappable model setting) the relationship will be stored in the migration using a reference to the setting, not to the model directly.

You only want to override this to be `False` if you are sure your model should always point toward

the swapped-in model - for example, if it is a profile model designed specifically for your custom user model.

If in doubt, leave it to its default of `True`.

ManyToManyField does not support *validators*.

null has no effect since there is no way to require a relationship at the database level.

OneToOneField

```
class OneToOneField(to, on_delete, parent_link=False, **options)
```

A one-to-one relationship. Conceptually, this is similar to a *ForeignKey* with *unique=True*, but the “reverse” side of the relation will directly return a single object.

This is most useful as the primary key of a model which “extends” another model in some way; *Multi-table inheritance* is implemented by adding an implicit one-to-one relation from the child model to the parent model, for example.

One positional argument is required: the class to which the model will be related. This works exactly the same as it does for *ForeignKey*, including all the options regarding *recursive* and *lazy* relationships.

If you do not specify the *related_name* argument for the *OneToOneField*, Django will use the lowercase name of the current model as default value.

With the following example:

```
from django.conf import settings
from django.db import models

class MySpecialUser(models.Model):
    user = models.OneToOneField(
        settings.AUTH_USER_MODEL,
        on_delete=models.CASCADE,
    )
    supervisor = models.OneToOneField(
        settings.AUTH_USER_MODEL,
        on_delete=models.CASCADE,
        related_name="supervisor_of",
    )
```

your resulting *User* model will have the following attributes:

```
>>> user = User.objects.get(pk=1)
>>> hasattr(user, "myspecialuser")
```

(continues on next page)

(continued from previous page)

```
True
>>> hasattr(user, "supervisor_of")
True
```

A `RelatedObjectDoesNotExist` exception is raised when accessing the reverse relationship if an entry in the related table doesn't exist. This is a subclass of the target model's `Model.DoesNotExist` exception and can be accessed as an attribute of the reverse accessor. For example, if a user doesn't have a supervisor designated by `MySpecialUser`:

```
try:
    user.supervisor_of
except User.supervisor_of.RelatedObjectDoesNotExist:
    pass
```

Additionally, `OneToOneField` accepts all of the extra arguments accepted by `ForeignKey`, plus one extra argument:

`OneToOneField.parent_link`

When `True` and used in a model which inherits from another [concrete model](#), indicates that this field should be used as the link back to the parent class, rather than the extra `OneToOneField` which would normally be implicitly created by subclassing.

See [One-to-one relationships](#) for usage examples of `OneToOneField`.

Field API reference

class `Field`

`Field` is an abstract class that represents a database table column. Django uses fields to create the database table (`db_type()`), to map Python types to database (`get_prep_value()`) and vice-versa (`from_db_value()`).

A field is thus a fundamental piece in different Django APIs, notably, [models](#) and [querysets](#).

In models, a field is instantiated as a class attribute and represents a particular table column, see [Models](#). It has attributes such as `null` and `unique`, and methods that Django uses to map the field value to database-specific values.

A `Field` is a subclass of `RegisterLookupMixin` and thus both `Transform` and `Lookup` can be registered on it to be used in QuerySets (e.g. `field_name__exact="foo"`). All [built-in lookups](#) are registered by default.

All of Django's built-in fields, such as `CharField`, are particular implementations of `Field`. If you need a custom field, you can either subclass any of the built-in fields or write a `Field` from scratch. In either case, see [How to create custom model fields](#).

description

A verbose description of the field, e.g. for the *django.contrib.admindocs* application.

The description can be of the form:

```
description = _("String (up to %(max_length)s)")
```

where the arguments are interpolated from the field's `s__dict__`.

descriptor_class

A class implementing the [descriptor protocol](#) that is instantiated and assigned to the model instance attribute. The constructor must accept a single argument, the `Field` instance. Overriding this class attribute allows for customizing the get and set behavior.

To map a `Field` to a database-specific type, Django exposes several methods:

get_internal_type()

Returns a string naming this field for backend specific purposes. By default, it returns the class name.

See [Emulating built-in field types](#) for usage in custom fields.

db_type(connection)

Returns the database column data type for the *Field*, taking into account the `connection`.

See [Custom database types](#) for usage in custom fields.

rel_db_type(connection)

Returns the database column data type for fields such as `ForeignKey` and `OneToOneField` that point to the *Field*, taking into account the `connection`.

See [Custom database types](#) for usage in custom fields.

There are three main situations where Django needs to interact with the database backend and fields:

- when it queries the database (Python value -> database backend value)
- when it loads data from the database (database backend value -> Python value)
- when it saves to the database (Python value -> database backend value)

When querying, *get_db_prep_value()* and *get_prep_value()* are used:

get_prep_value(value)

`value` is the current value of the model's attribute, and the method should return data in a format that has been prepared for use as a parameter in a query.

See [Converting Python objects to query values](#) for usage.

get_db_prep_value(value, connection, prepared=False)

Converts *value* to a backend-specific value. By default it returns *value* if *prepared=True* and *get_prep_value()* if is *False*.

See [Converting query values to database values](#) for usage.

When loading data, *from_db_value()* is used:

from_db_value(value, expression, connection)

Converts a value as returned by the database to a Python object. It is the reverse of *get_prep_value()*.

This method is not used for most built-in fields as the database backend already returns the correct Python type, or the backend itself does the conversion.

expression is the same as *self*.

See [Converting values to Python objects](#) for usage.

Note: For performance reasons, *from_db_value* is not implemented as a no-op on fields which do not require it (all Django fields). Consequently you may not call *super* in your definition.

When saving, *pre_save()* and *get_db_prep_save()* are used:

get_db_prep_save(value, connection)

Same as the *get_db_prep_value()*, but called when the field value must be saved to the database. By default returns *get_db_prep_value()*.

pre_save(model_instance, add)

Method called prior to *get_db_prep_save()* to prepare the value before being saved (e.g. for *DateField.auto_now*).

model_instance is the instance this field belongs to and *add* is whether the instance is being saved to the database for the first time.

It should return the value of the appropriate attribute from *model_instance* for this field. The attribute name is in *self.attname* (this is set up by *Field*).

See [Preprocessing values before saving](#) for usage.

Fields often receive their values as a different type, either from serialization or from forms.

to_python(value)

Converts the value into the correct Python object. It acts as the reverse of *value_to_string()*, and is also called in *clean()*.

See [Converting values to Python objects](#) for usage.

Besides saving to the database, the field also needs to know how to serialize its value:

`value_from_object(obj)`

Returns the field's value for the given model instance.

This method is often used by `value_to_string()`.

`value_to_string(obj)`

Converts `obj` to a string. Used to serialize the value of the field.

See [Converting field data for serialization](#) for usage.

When using *model forms*, the `Field` needs to know which form field it should be represented by:

`formfield(form_class=None, choices_form_class=None, **kwargs)`

Returns the default `django.forms.Field` of this field for *ModelForm*.

By default, if both `form_class` and `choices_form_class` are `None`, it uses `CharField`. If the field has `choices` and `choices_form_class` isn't specified, it uses `TypedChoiceField`.

See [Specifying the form field for a model field](#) for usage.

`deconstruct()`

Returns a 4-tuple with enough information to recreate the field:

1. The name of the field on the model.
2. The import path of the field (e.g. `"django.db.models.IntegerField"`). This should be the most portable version, so less specific may be better.
3. A list of positional arguments.
4. A dict of keyword arguments.

This method must be added to fields prior to 1.7 to migrate its data using [Migrations](#).

Registering and fetching lookups

`Field` implements the [lookup registration API](#). The API can be used to customize which lookups are available for a field class and its instances, and how lookups are fetched from a field.

Support for registering lookups on *Field* instances was added.

6.16.2 Field attribute reference

Every `Field` instance contains several attributes that allow introspecting its behavior. Use these attributes instead of `isinstance` checks when you need to write code that depends on a field's functionality. These attributes can be used together with the `Model._meta` API to narrow down a search for specific field types. Custom model fields should implement these flags.

Attributes for fields

`Field.auto_created`

Boolean flag that indicates if the field was automatically created, such as the `OneToOneField` used by model inheritance.

`Field.concrete`

Boolean flag that indicates if the field has a database column associated with it.

`Field.hidden`

Boolean flag that indicates if a field is used to back another non-hidden field's functionality (e.g. the `content_type` and `object_id` fields that make up a `GenericForeignKey`). The `hidden` flag is used to distinguish what constitutes the public subset of fields on the model from all the fields on the model.

Note: `Options.get_fields()` excludes hidden fields by default. Pass in `include_hidden=True` to return hidden fields in the results.

`Field.is_relation`

Boolean flag that indicates if a field contains references to one or more other models for its functionality (e.g. `ForeignKey`, `ManyToManyField`, `OneToOneField`, etc.).

`Field.model`

Returns the model on which the field is defined. If a field is defined on a superclass of a model, `model` will refer to the superclass, not the class of the instance.

Attributes for fields with relations

These attributes are used to query for the cardinality and other details of a relation. These attribute are present on all fields; however, they will only have boolean values (rather than `None`) if the field is a relation type (`Field.is_relation=True`).

`Field.many_to_many`

Boolean flag that is `True` if the field has a many-to-many relation; `False` otherwise. The only field included with Django where this is `True` is `ManyToManyField`.

`Field.many_to_one`

Boolean flag that is `True` if the field has a many-to-one relation, such as a `ForeignKey`; `False` otherwise.

`Field.one_to_many`

Boolean flag that is `True` if the field has a one-to-many relation, such as a `GenericRelation` or the reverse of a `ForeignKey`; `False` otherwise.

`Field.one_to_one`

Boolean flag that is `True` if the field has a one-to-one relation, such as a `OneToOneField`; `False` otherwise.

`Field.related_model`

Points to the model the field relates to. For example, `Author` in `ForeignKey(Author, on_delete=models.CASCADE)`. The `related_model` for a `GenericForeignKey` is always `None`.

6.16.3 Model index reference

Index classes ease creating database indexes. They can be added using the *`Meta.indexes`* option. This document explains the API references of *`Index`* which includes the *index options*.

Referencing built-in indexes

Indexes are defined in `django.db.models.indexes`, but for convenience they're imported into *`django.db.models`*. The standard convention is to use `from django.db import models` and refer to the indexes as `models.<IndexClass>`.

Index options

```
class Index(*expressions, fields=(), name=None, db_tablespace=None, opclasses=(), condition=None,
            include=None)
```

Creates an index (B-Tree) in the database.

expressions

`Index.expressions`

Positional argument *`*expressions`* allows creating functional indexes on expressions and database functions.

For example:

```
Index(Lower("title").desc(), "pub_date", name="lower_title_date_idx")
```

creates an index on the lowercased value of the `title` field in descending order and the `pub_date` field in the default ascending order.

Another example:

```
Index(F("height") * F("weight"), Round("weight"), name="calc_idx")
```

creates an index on the result of multiplying fields `height` and `weight` and the `weight` rounded to the nearest integer.

`Index.name` is required when using `*expressions`.

Restrictions on Oracle

Oracle requires functions referenced in an index to be marked as DETERMINISTIC. Django doesn't validate this but Oracle will error. This means that functions such as `Random()` aren't accepted.

Restrictions on PostgreSQL

PostgreSQL requires functions and operators referenced in an index to be marked as IMMUTABLE. Django doesn't validate this but PostgreSQL will error. This means that functions such as `Concat()` aren't accepted.

MySQL and MariaDB

Functional indexes are ignored with MySQL < 8.0.13 and MariaDB as neither supports them.

fields

`Index.fields`

A list or tuple of the name of the fields on which the index is desired.

By default, indexes are created with an ascending order for each column. To define an index with a descending order for a column, add a hyphen before the field's name.

For example `Index(fields=['headline', '-pub_date'])` would create SQL with `(headline, pub_date DESC)`.

MySQL and MariaDB

Index ordering isn't supported on MySQL < 8.0.1 and MariaDB < 10.8. In that case, a descending index is created as a normal index.

`name`

`Index.name`

The name of the index. If `name` isn't provided Django will auto-generate a name. For compatibility with different databases, index names cannot be longer than 30 characters and shouldn't start with a number (0-9) or underscore (`_`).

Partial indexes in abstract base classes

You must always specify a unique name for an index. As such, you cannot normally specify a partial index on an abstract base class, since the `Meta.indexes` option is inherited by subclasses, with exactly the same values for the attributes (including `name`) each time. To work around name collisions, part of the name may contain `'%(app_label)s'` and `'%(class)s'`, which are replaced, respectively, by the lowercased app label and class name of the concrete model. For example `Index(fields=['title'], name='%(app_label)s_%(class)s_title_index')`.

`db_tablespace`

`Index.db_tablespace`

The name of the [database tablespace](#) to use for this index. For single field indexes, if `db_tablespace` isn't provided, the index is created in the `db_tablespace` of the field.

If `Field.db_tablespace` isn't specified (or if the index uses multiple fields), the index is created in tablespace specified in the `db_tablespace` option inside the model's class `Meta`. If neither of those tablespaces are set, the index is created in the same tablespace as the table.

See also:

For a list of PostgreSQL-specific indexes, see [django.contrib.postgres.indexes](#).

`opclasses`

`Index.opclasses`

The names of the [PostgreSQL operator classes](#) to use for this index. If you require a custom operator class, you must provide one for each field in the index.

For example, `GinIndex(name='json_index', fields=['jsonfield'], opclasses=['jsonb_path_ops'])` creates a gin index on `jsonfield` using `jsonb_path_ops`.

`opclasses` are ignored for databases besides PostgreSQL.

[Index.name](#) is required when using `opclasses`.

`condition`

`Index.condition`

If the table is very large and your queries mostly target a subset of rows, it may be useful to restrict an index to that subset. Specify a condition as a *Q*. For example, `condition=Q(pages__gt=400)` indexes records with more than 400 pages.

Index.name is required when using `condition`.

Restrictions on PostgreSQL

PostgreSQL requires functions referenced in the condition to be marked as IMMUTABLE. Django doesn't validate this but PostgreSQL will error. This means that functions such as *Date functions* and *Concat* aren't accepted. If you store dates in *DateTimeField*, comparison to *datetime* objects may require the *tzinfo* argument to be provided because otherwise the comparison could result in a mutable function due to the casting Django does for *lookups*.

Restrictions on SQLite

SQLite *imposes restrictions* on how a partial index can be constructed.

Oracle

Oracle does not support partial indexes. Instead, partial indexes can be emulated by using functional indexes together with *Case* expressions.

MySQL and MariaDB

The `condition` argument is ignored with MySQL and MariaDB as neither supports conditional indexes.

`include`

`Index.include`

A list or tuple of the names of the fields to be included in the covering index as non-key columns. This allows index-only scans to be used for queries that select only included fields (*include*) and filter only by indexed fields (*fields*).

For example:

```
Index(name="covering_index", fields=["headline"], include=["pub_date"])
```

will allow filtering on `headline`, also selecting `pub_date`, while fetching data only from the index.

Using `include` will produce a smaller index than using a multiple column index but with the drawback that non-key columns can not be used for sorting or filtering.

`include` is ignored for databases besides PostgreSQL.

Index.name is required when using `include`.

See the PostgreSQL documentation for more details about [covering indexes](#).

Restrictions on PostgreSQL

PostgreSQL supports covering B-Tree and *GiST indexes*. PostgreSQL 14+ also supports covering *SP-GiST indexes*.

Support for covering SP-GiST indexes with PostgreSQL 14+ was added.

6.16.4 Constraints reference

The classes defined in this module create database constraints. They are added in the model *Meta.constraints* option.

Referencing built-in constraints

Constraints are defined in `django.db.models.constraints`, but for convenience they're imported into `django.db.models`. The standard convention is to use `from django.db import models` and refer to the constraints as `models.<Foo>Constraint`.

Constraints in abstract base classes

You must always specify a unique name for the constraint. As such, you cannot normally specify a constraint on an abstract base class, since the *Meta.constraints* option is inherited by subclasses, with exactly the same values for the attributes (including `name`) each time. To work around name collisions, part of the name may contain `'%(app_label)s'` and `'%(class)s'`, which are replaced, respectively, by the lowercased app label and class name of the concrete model. For example `CheckConstraint(check=Q(age__gte=18), name='%(app_label)s_%(class)s_is_adult')`.

Validation of Constraints

Constraints are checked during the [model validation](#).

Validation of Constraints with `JSONField`

Constraints containing `JSONField` may not raise validation errors as key, index, and path transforms have many database-specific caveats. This [may be fully supported later](#).

You should always check that there are no log messages, in the `django.db.models` logger, like “Got a database error calling `check()` on ...” to confirm it’s validated properly.

In older versions, constraints were not checked during model validation.

`BaseConstraint`

```
class BaseConstraint(name, violation_error_message=None)
```

Base class for all constraints. Subclasses must implement `constraint_sql()`, `create_sql()`, `remove_sql()` and `validate()` methods.

All constraints have the following parameters in common:

`name`

`BaseConstraint.name`

The name of the constraint. You must always specify a unique name for the constraint.

`violation_error_message`

`BaseConstraint.violation_error_message`

The error message used when `ValidationError` is raised during [model validation](#). Defaults to “Constraint “%(name)s” is violated.”.

`validate()`

`BaseConstraint.validate(model, instance, exclude=None, using=DEFAULT_DB_ALIAS)`

Validates that the constraint, defined on `model`, is respected on the `instance`. This will do a query on the database to ensure that the constraint is respected. If fields in the `exclude` list are needed to validate the constraint, the constraint is ignored.

Raise a `ValidationError` if the constraint is violated.

This method must be implemented by a subclass.

`CheckConstraint`

```
class CheckConstraint(*, check, name, violation_error_message=None)
```

Creates a check constraint in the database.

`check`

`CheckConstraint.check`

A `Q` object or boolean *Expression* that specifies the check you want the constraint to enforce.

For example, `CheckConstraint(check=Q(age__gte=18), name='age_gte_18')` ensures the `age` field is never less than 18.

Oracle

Checks with nullable fields on Oracle must include a condition allowing for `NULL` values in order for *validate()* to behave the same as check constraints validation. For example, if `age` is a nullable field:

```
CheckConstraint(check=Q(age__gte=18) | Q(age__isnull=True), name="age_gte_18")
```

The `violation_error_message` argument was added.

`UniqueConstraint`

```
class UniqueConstraint(*expressions, fields=(), name=None, condition=None, deferrable=None,
                      include=None, opclasses=(), violation_error_message=None)
```

Creates a unique constraint in the database.

`expressions`

`UniqueConstraint.expressions`

Positional argument `*expressions` allows creating functional unique constraints on expressions and database functions.

For example:

```
UniqueConstraint(Lower("name").desc(), "category", name="unique_lower_name_category")
```

creates a unique constraint on the lowercased value of the `name` field in descending order and the `category` field in the default ascending order.

Functional unique constraints have the same database restrictions as *[Index.expressions](#)*.

`fields`

`UniqueConstraint.fields`

A list of field names that specifies the unique set of columns you want the constraint to enforce.

For example, `UniqueConstraint(fields=['room', 'date'], name='unique_booking')` ensures each room can only be booked once for each date.

`condition`

`UniqueConstraint.condition`

A *[Q](#)* object that specifies the condition you want the constraint to enforce.

For example:

```
UniqueConstraint(fields=["user"], condition=Q(status="DRAFT"), name="unique_draft_user")
```

ensures that each user only has one draft.

These conditions have the same database restrictions as *[Index.condition](#)*.

`deferrable`

`UniqueConstraint.deferrable`

Set this parameter to create a deferrable unique constraint. Accepted values are `Deferrable.DEFERRED` or `Deferrable.IMMEDIATE`. For example:

```
from django.db.models import Deferrable, UniqueConstraint

UniqueConstraint(
    name="unique_order",
    fields=["order"],
    deferrable=Deferrable.DEFERRED,
)
```

By default constraints are not deferred. A deferred constraint will not be enforced until the end of the transaction. An immediate constraint will be enforced immediately after every command.

MySQL, MariaDB, and SQLite.

Deferrable unique constraints are ignored on MySQL, MariaDB, and SQLite as neither supports them.

Warning: Deferred unique constraints may lead to a [performance penalty](#).

`include`

`UniqueConstraint.include`

A list or tuple of the names of the fields to be included in the covering unique index as non-key columns. This allows index-only scans to be used for queries that select only included fields (*include*) and filter only by unique fields (*fields*).

For example:

```
UniqueConstraint(name="unique_booking", fields=["room", "date"], include=["full_name"])
```

will allow filtering on `room` and `date`, also selecting `full_name`, while fetching data only from the index.

`include` is supported only on PostgreSQL.

Non-key columns have the same database restrictions as *Index.include*.

`opclasses`

`UniqueConstraint.opclasses`

The names of the PostgreSQL operator classes to use for this unique index. If you require a custom operator class, you must provide one for each field in the index.

For example:

```
UniqueConstraint(  
    name="unique_username", fields=["username"], opclasses=["varchar_pattern_ops"]  
)
```

creates a unique index on `username` using `varchar_pattern_ops`.

`opclasses` are ignored for databases besides PostgreSQL.

`violation_error_message`

`UniqueConstraint.violation_error_message`

The error message used when `ValidationError` is raised during `model validation`. Defaults to `BaseConstraint.violation_error_message`.

This message is not used for `UniqueConstraints` with `fields` and without a `condition`. Such `UniqueConstraints` show the same message as constraints defined with `Field.unique` or in `Meta.unique_together`.

6.16.5 Model `_meta` API

`class Options`

The `model _meta` API is at the core of the Django ORM. It enables other parts of the system such as lookups, queries, forms, and the admin to understand the capabilities of each model. The API is accessible through the `_meta` attribute of each model class, which is an instance of an `django.db.models.options.Options` object.

Methods that it provides can be used to:

- Retrieve all field instances of a model
- Retrieve a single field instance of a model by name

Field access API

Retrieving a single field instance of a model by name

`Options.get_field(field_name)`

Returns the field instance given a name of a field.

`field_name` can be the name of a field on the model, a field on an abstract or inherited model, or a field defined on another model that points to the model. In the latter case, the `field_name` will be (in order of preference) the `related_query_name` set by the user, the `related_name` set by the user, or the name automatically generated by Django.

Hidden fields cannot be retrieved by name.

If a field with the given name is not found a `FieldDoesNotExist` exception will be raised.

```
>>> from django.contrib.auth.models import User

# A field on the model
>>> User._meta.get_field("username")
```

(continues on next page)

(continued from previous page)

```

<django.db.models.fields.CharField: username>

# A field from another model that has a relation with the current model
>>> User._meta.get_field("logentry")
<ManyToOneRel: admin.logentry>

# A non existent field
>>> User._meta.get_field("does_not_exist")
Traceback (most recent call last):
...
FieldDoesNotExist: User has no field named 'does_not_exist'

```

Retrieving all field instances of a model

`Options.get_fields(include_parents=True, include_hidden=False)`

Returns a tuple of fields associated with a model. `get_fields()` accepts two parameters that can be used to control which fields are returned:

`include_parents`

True by default. Recursively includes fields defined on parent classes. If set to `False`, `get_fields()` will only search for fields declared directly on the current model. Fields from models that directly inherit from abstract models or proxy classes are considered to be local, not on the parent.

`include_hidden`

False by default. If set to `True`, `get_fields()` will include fields that are used to back other field's functionality. This will also include any fields that have a `related_name` (such as *ManyToManyField*, or *ForeignKey*) that start with a "+" .

```

>>> from django.contrib.auth.models import User
>>> User._meta.get_fields()
(<ManyToOneRel: admin.logentry>,
 <django.db.models.fields.AutoField: id>,
 <django.db.models.fields.CharField: password>,
 <django.db.models.fields.DateTimeField: last_login>,
 <django.db.models.fields.BooleanField: is_superuser>,
 <django.db.models.fields.CharField: username>,
 <django.db.models.fields.CharField: first_name>,
 <django.db.models.fields.CharField: last_name>,
 <django.db.models.fields.EmailField: email>,
 <django.db.models.fields.BooleanField: is_staff>,
 <django.db.models.fields.BooleanField: is_active>,

```

(continues on next page)

(continued from previous page)

```

<django.db.models.fields.DateTimeField: date_joined>,
<django.db.models.fields.related.ManyToManyField: groups>,
<django.db.models.fields.related.ManyToManyField: user_permissions>)

# Also include hidden fields.
>>> User._meta.get_fields(include_hidden=True)
(<ManyToOneRel: auth.user_groups>,
 <ManyToOneRel: auth.user_user_permissions>,
 <ManyToOneRel: admin.logentry>,
 <django.db.models.fields.AutoField: id>,
 <django.db.models.fields.CharField: password>,
 <django.db.models.fields.DateTimeField: last_login>,
 <django.db.models.fields.BooleanField: is_superuser>,
 <django.db.models.fields.CharField: username>,
 <django.db.models.fields.CharField: first_name>,
 <django.db.models.fields.CharField: last_name>,
 <django.db.models.fields.EmailField: email>,
 <django.db.models.fields.BooleanField: is_staff>,
 <django.db.models.fields.BooleanField: is_active>,
 <django.db.models.fields.DateTimeField: date_joined>,
 <django.db.models.fields.related.ManyToManyField: groups>,
 <django.db.models.fields.related.ManyToManyField: user_permissions>)

```

6.16.6 Related objects reference

class RelatedManager

A “related manager” is a manager used in a one-to-many or many-to-many related context. This happens in two cases:

- The “other side” of a *ForeignKey* relation. That is:

```

from django.db import models

class Blog(models.Model):
    # ...
    pass

class Entry(models.Model):
    blog = models.ForeignKey(Blog, on_delete=models.CASCADE, null=True)

```

In the above example, the methods below will be available on the manager `blog.entry_set`.

- Both sides of a *ManyToManyField* relation

```
class Topping(models.Model):
    # ...
    pass

class Pizza(models.Model):
    toppings = models.ManyToManyField(Topping)
```

In this example, the methods below will be available both on `topping.pizza_set` and on `pizza.toppings`.

`add(*objs, bulk=True, through_defaults=None)`

`aadd(*objs, bulk=True, through_defaults=None)`

Asynchronous version: `aadd`

Adds the specified model objects to the related object set.

Example:

```
>>> b = Blog.objects.get(id=1)
>>> e = Entry.objects.get(id=234)
>>> b.entry_set.add(e) # Associates Entry e with Blog b.
```

In the example above, in the case of a *ForeignKey* relationship, `QuerySet.update()` is used to perform the update. This requires the objects to already be saved.

You can use the `bulk=False` argument to instead have the related manager perform the update by calling `e.save()`.

Using `add()` with a many-to-many relationship, however, will not call any `save()` methods (the `bulk` argument doesn't exist), but rather create the relationships using `QuerySet.bulk_create()`. If you need to execute some custom logic when a relationship is created, listen to the `m2m_changed` signal, which will trigger `pre_add` and `post_add` actions.

Using `add()` on a relation that already exists won't duplicate the relation, but it will still trigger signals.

For many-to-many relationships `add()` accepts either model instances or field values, normally primary keys, as the `*objs` argument.

Use the `through_defaults` argument to specify values for the new *intermediate model* instance(s), if needed. You can use callables as values in the `through_defaults` dictionary and they will be evaluated once before creating any intermediate instance(s).

`aadd()` method was added.

`create(through_defaults=None, **kwargs)`

`acreate(through_defaults=None, **kwargs)`

Asynchronous version: `acreate`

Creates a new object, saves it and puts it in the related object set. Returns the newly created object:

```
>>> b = Blog.objects.get(id=1)
>>> e = b.entry_set.create(
...     headline="Hello", body_text="Hi", pub_date=datetime.date(2005, 1, 1)
... )

# No need to call e.save() at this point -- it's already been saved.
```

This is equivalent to (but simpler than):

```
>>> b = Blog.objects.get(id=1)
>>> e = Entry(blog=b, headline="Hello", body_text="Hi", pub_date=datetime.date(2005, 1, 1))
>>> e.save(force_insert=True)
```

Note that there's no need to specify the keyword argument of the model that defines the relationship. In the above example, we don't pass the parameter `blog` to `create()`. Django figures out that the new `Entry` object's `blog` field should be set to `b`.

Use the `through_defaults` argument to specify values for the new [intermediate model](#) instance, if needed. You can use callables as values in the `through_defaults` dictionary.

`acreate()` method was added.

`remove(*objs, bulk=True)`

`aremove(*objs, bulk=True)`

Asynchronous version: `aremove`

Removes the specified model objects from the related object set:

```
>>> b = Blog.objects.get(id=1)
>>> e = Entry.objects.get(id=234)
>>> b.entry_set.remove(e) # Disassociates Entry e from Blog b.
```

Similar to `add()`, `e.save()` is called in the example above to perform the update. Using `remove()` with a many-to-many relationship, however, will delete the relationships using `QuerySet.delete()` which means no model `save()` methods are called; listen to the `m2m_changed` signal if you wish to execute custom code when a relationship is deleted.

For many-to-many relationships `remove()` accepts either model instances or field values, normally primary keys, as the `*objs` argument.

For *ForeignKey* objects, this method only exists if `null=True`. If the related field can't be set to `None` (`NULL`), then an object can't be removed from a relation without being added to another. In the above example, removing `e` from `b.entry_set()` is equivalent to doing `e.blog = None`, and because the `blog ForeignKey` doesn't have `null=True`, this is invalid.

For *ForeignKey* objects, this method accepts a `bulk` argument to control how to perform the operation. If `True` (the default), `QuerySet.update()` is used. If `bulk=False`, the `save()` method of each individual model instance is called instead. This triggers the `pre_save` and `post_save` signals and comes at the expense of performance.

For many-to-many relationships, the `bulk` keyword argument doesn't exist.

`aremove()` method was added.

`clear(bulk=True)`

`aclear(bulk=True)`

Asynchronous version: `aclear`

Removes all objects from the related object set:

```
>>> b = Blog.objects.get(id=1)
>>> b.entry_set.clear()
```

Note this doesn't delete the related objects—it just disassociates them.

Just like `remove()`, `clear()` is only available on *ForeignKeys* where `null=True` and it also accepts the `bulk` keyword argument.

For many-to-many relationships, the `bulk` keyword argument doesn't exist.

`aclear()` method was added.

`set(objs, bulk=True, clear=False, through_defaults=None)`

`aset(objs, bulk=True, clear=False, through_defaults=None)`

Asynchronous version: `aset`

Replace the set of related objects:

```
>>> new_list = [obj1, obj2, obj3]
>>> e.related_set.set(new_list)
```

This method accepts a `clear` argument to control how to perform the operation. If `False` (the default), the elements missing from the new set are removed using `remove()` and only the new ones are added. If `clear=True`, the `clear()` method is called instead and the whole set is added at once.

For *ForeignKey* objects, the `bulk` argument is passed on to `add()` and `remove()`.

For many-to-many relationships, the `bulk` keyword argument doesn't exist.

Note that since `set()` is a compound operation, it is subject to race conditions. For instance, new objects may be added to the database in between the call to `clear()` and the call to `add()`.

For many-to-many relationships `set()` accepts a list of either model instances or field values, normally primary keys, as the `objs` argument.

Use the `through_defaults` argument to specify values for the new [intermediate model](#) instance(s), if needed. You can use callables as values in the `through_defaults` dictionary and they will be evaluated once before creating any intermediate instance(s).

`aset()` method was added.

Note: Note that `add()`, `aadd()`, `create()`, `acreate()`, `remove()`, `aremove()`, `clear()`, `aclear()`, `set()`, and `aset()` all apply database changes immediately for all types of related fields. In other words, there is no need to call `save()/asave()` on either end of the relationship.

If you use `prefetch_related()`, the `add()`, `aadd()`, `remove()`, `aremove()`, `clear()`, `aclear()`, `set()`, and `aset()` methods clear the prefetched cache.

6.16.7 Model class reference

This document covers features of the [Model](#) class. For more information about models, see [the complete list of Model reference guides](#).

Attributes

`DoesNotExist`

exception `Model.DoesNotExist`

This exception is raised by the ORM when an expected object is not found. For example, `QuerySet.get()` will raise it when no object is found for the given lookups.

Django provides a `DoesNotExist` exception as an attribute of each model class to identify the class of object that could not be found, allowing you to catch exceptions for a particular model class. The exception is a subclass of `django.core.exceptions.ObjectDoesNotExist`.

MultipleObjectsReturned

exception `Model.MultipleObjectsReturned`

This exception is raised by `QuerySet.get()` when multiple objects are found for the given lookups.

Django provides a `MultipleObjectsReturned` exception as an attribute of each model class to identify the class of object for which multiple objects were found, allowing you to catch exceptions for a particular model class. The exception is a subclass of `django.core.exceptions.MultipleObjectsReturned`.

objects

`Model.objects`

Each non-abstract *Model* class must have a *Manager* instance added to it. Django ensures that in your model class you have at least a default *Manager* specified. If you don't add your own *Manager*, Django will add an attribute `objects` containing default *Manager* instance. If you add your own *Manager* instance attribute, the default one does not appear. Consider the following example:

```
from django.db import models

class Person(models.Model):
    # Add manager with another name
    people = models.Manager()
```

For more details on model managers see [Managers](#) and [Retrieving objects](#).

6.16.8 Model Meta options

This document explains all the possible [metadata options](#) that you can give your model in its internal `class Meta`.

Available Meta options

`abstract`

`Options.abstract`

If `abstract = True`, this model will be an [abstract base class](#).

`app_label`

`Options.app_label`

If a model is defined outside of an application in *INSTALLED_APPS*, it must declare which app it belongs to:

```
app_label = "myapp"
```

If you want to represent a model with the format `app_label.object_name` or `app_label.model_name` you can use `model._meta.label` or `model._meta.label_lower` respectively.

`base_manager_name`

`Options.base_manager_name`

The attribute name of the manager, for example, 'objects', to use for the model's *base_manager*.

`db_table`

`Options.db_table`

The name of the database table to use for the model:

```
db_table = "music_album"
```

Table names

To save you time, Django automatically derives the name of the database table from the name of your model class and the app that contains it. A model's database table name is constructed by joining the model's "app label"—the name you used in *manage.py startapp*—to the model's class name, with an underscore between them.

For example, if you have an app `bookstore` (as created by *manage.py startapp bookstore*), a model defined as `class Book` will have a database table named `bookstore_book`.

To override the database table name, use the `db_table` parameter in `class Meta`.

If your database table name is an SQL reserved word, or contains characters that aren't allowed in Python variable names—notably, the hyphen—that's OK. Django quotes column and table names behind the scenes.

Use lowercase table names for MariaDB and MySQL

It is strongly advised that you use lowercase table names when you override the table name via `db_table`, particularly if you are using the MySQL backend. See the [MySQL notes](#) for more details.

Table name quoting for Oracle

In order to meet the 30-char limitation Oracle has on table names, and match the usual conventions for Oracle databases, Django may shorten table names and turn them all-uppercase. To prevent such transformations, use a quoted name as the value for `db_table`:

```
db_table = "name_left_in_lowercase"
```

Such quoted names can also be used with Django's other supported database backends; except for Oracle, however, the quotes have no effect. See the [Oracle notes](#) for more details.

`db_table_comment`

`Options.db_table_comment`

The comment on the database table to use for this model. It is useful for documenting database tables for individuals with direct database access who may not be looking at your Django code. For example:

```
class Answer(models.Model):
    question = models.ForeignKey(Question, on_delete=models.CASCADE)
    answer = models.TextField()

    class Meta:
        db_table_comment = "Question answers"
```

`db_tablespace`

`Options.db_tablespace`

The name of the [database tablespace](#) to use for this model. The default is the project's [DEFAULT_TABLESPACE](#) setting, if set. If the backend doesn't support tablespaces, this option is ignored.

`default_manager_name`

`Options.default_manager_name`

The name of the manager to use for the model's `_default_manager`.

`default_related_name`

`Options.default_related_name`

The name that will be used by default for the relation from a related object back to this one. The default is `<model_name>_set`.

This option also sets *related_query_name*.

As the reverse name for a field should be unique, be careful if you intend to subclass your model. To work around name collisions, part of the name should contain `'%(app_label)s'` and `'%(model_name)s'`, which are replaced respectively by the name of the application the model is in, and the name of the model, both lowercased. See the paragraph on [related names for abstract models](#).

`get_latest_by`

`Options.get_latest_by`

The name of a field or a list of field names in the model, typically *DateTimeField*, *IntegerField*, or *IntegerField*. This specifies the default field(s) to use in your model *Manager*'s *latest()* and *earliest()* methods.

Example:

```
# Latest by ascending order_date.
get_latest_by = "order_date"

# Latest by priority descending, order_date ascending.
get_latest_by = ["-priority", "order_date"]
```

See the *latest()* docs for more.

`managed`

`Options.managed`

Defaults to `True`, meaning Django will create the appropriate database tables in *migrate* or as part of migrations and remove them as part of a *flush* management command. That is, Django manages the database tables' lifecycles.

If `False`, no database table creation, modification, or deletion operations will be performed for this model. This is useful if the model represents an existing table or a database view that has been created by some other means. This is the only difference when `managed=False`. All other aspects of model handling are exactly the same as normal. This includes

1. Adding an automatic primary key field to the model if you don't declare it. To avoid confusion for later code readers, it's recommended to specify all the columns from the database table you

are modeling when using unmanaged models.

2. If a model with `managed=False` contains a *ManyToManyField* that points to another unmanaged model, then the intermediate table for the many-to-many join will also not be created. However, the intermediary table between one managed and one unmanaged model will be created.

If you need to change this default behavior, create the intermediary table as an explicit model (with `managed` set as needed) and use the *ManyToManyField.through* attribute to make the relation use your custom model.

For tests involving models with `managed=False`, it's up to you to ensure the correct tables are created as part of the test setup.

If you're interested in changing the Python-level behavior of a model class, you could use `managed=False` and create a copy of an existing model. However, there's a better approach for that situation: [Proxy models](#).

`order_with_respect_to`

`Options.order_with_respect_to`

Makes this object orderable with respect to the given field, usually a `ForeignKey`. This can be used to make related objects orderable with respect to a parent object. For example, if an `Answer` relates to a `Question` object, and a question has more than one answer, and the order of answers matters, you'd do this:

```
from django.db import models

class Question(models.Model):
    text = models.TextField()
    # ...

class Answer(models.Model):
    question = models.ForeignKey(Question, on_delete=models.CASCADE)
    # ...

    class Meta:
        order_with_respect_to = "question"
```

When `order_with_respect_to` is set, two additional methods are provided to retrieve and to set the order of the related objects: `get_RELATED_order()` and `set_RELATED_order()`, where `RELATED` is the lowercased model name. For example, assuming that a `Question` object has multiple related `Answer` objects, the list returned contains the primary keys of the related `Answer` objects:

```
>>> question = Question.objects.get(id=1)
>>> question.get_answer_order()
[1, 2, 3]
```

The order of a `Question` object's related `Answer` objects can be set by passing in a list of `Answer` primary keys:

```
>>> question.set_answer_order([3, 1, 2])
```

The related objects also get two methods, `get_next_in_order()` and `get_previous_in_order()`, which can be used to access those objects in their proper order. Assuming the `Answer` objects are ordered by id:

```
>>> answer = Answer.objects.get(id=2)
>>> answer.get_next_in_order()
<Answer: 3>
>>> answer.get_previous_in_order()
<Answer: 1>
```

`order_with_respect_to` implicitly sets the `ordering` option

Internally, `order_with_respect_to` adds an additional field/database column named `_order` and sets the model's `ordering` option to this field. Consequently, `order_with_respect_to` and `ordering` cannot be used together, and the ordering added by `order_with_respect_to` will apply whenever you obtain a list of objects of this model.

Changing `order_with_respect_to`

Because `order_with_respect_to` adds a new database column, be sure to make and apply the appropriate migrations if you add or change `order_with_respect_to` after your initial *migrate*.

`ordering`

`Options.ordering`

The default ordering for the object, for use when obtaining lists of objects:

```
ordering = ["-order_date"]
```

This is a tuple or list of strings and/or query expressions. Each string is a field name with an optional “-” prefix, which indicates descending order. Fields without a leading “-” will be ordered ascending. Use the string “?” to order randomly.

For example, to order by a `pub_date` field ascending, use this:

```
ordering = ["pub_date"]
```

To order by `pub_date` descending, use this:

```
ordering = ["-pub_date"]
```

To order by `pub_date` descending, then by `author` ascending, use this:

```
ordering = ["-pub_date", "author"]
```

You can also use [query expressions](#). To order by `author` ascending and make null values sort last, use this:

```
from django.db.models import F

ordering = [F("author").asc(nulls_last=True)]
```

Warning: Ordering is not a free operation. Each field you add to the ordering incurs a cost to your database. Each foreign key you add will implicitly include all of its default orderings as well.

If a query doesn't have an ordering specified, results are returned from the database in an unspecified order. A particular ordering is guaranteed only when ordering by a set of fields that uniquely identify each object in the results. For example, if a `name` field isn't unique, ordering by it won't guarantee objects with the same name always appear in the same order.

permissions

`Options.permissions`

Extra permissions to enter into the permissions table when creating this object. Add, change, delete, and view permissions are automatically created for each model. This example specifies an extra permission, `can_deliver_pizzas`:

```
permissions = [("can_deliver_pizzas", "Can deliver pizzas")]
```

This is a list or tuple of 2-tuples in the format `(permission_code, human_readable_permission_name)`.

`default_permissions`

`Options.default_permissions`

Defaults to `('add', 'change', 'delete', 'view')`. You may customize this list, for example, by setting this to an empty list if your app doesn't require any of the default permissions. It must be specified on the model before the model is created by *migrate* in order to prevent any omitted permissions from being created.

`proxy`

`Options.proxy`

If `proxy = True`, a model which subclasses another model will be treated as a [proxy model](#).

`required_db_features`

`Options.required_db_features`

List of database features that the current connection should have so that the model is considered during the migration phase. For example, if you set this list to `['gis_enabled']`, the model will only be synchronized on GIS-enabled databases. It's also useful to skip some models when testing with several database backends. Avoid relations between models that may or may not be created as the ORM doesn't handle this.

`required_db_vendor`

`Options.required_db_vendor`

Name of a supported database vendor that this model is specific to. Current built-in vendor names are: `sqlite`, `postgresql`, `mysql`, `oracle`. If this attribute is not empty and the current connection vendor doesn't match it, the model will not be synchronized.

`select_on_save`

`Options.select_on_save`

Determines if Django will use the pre-1.6 *`django.db.models.Model.save()`* algorithm. The old algorithm uses `SELECT` to determine if there is an existing row to be updated. The new algorithm tries an `UPDATE` directly. In some rare cases the `UPDATE` of an existing row isn't visible to Django. An example is the PostgreSQL `ON UPDATE` trigger which returns `NULL`. In such cases the new algorithm will end up doing an `INSERT` even when a row exists in the database.

Usually there is no need to set this attribute. The default is `False`.

See *`django.db.models.Model.save()`* for more about the old and new saving algorithm.

indexes

Options.indexes

A list of [indexes](#) that you want to define on the model:

```
from django.db import models

class Customer(models.Model):
    first_name = models.CharField(max_length=100)
    last_name = models.CharField(max_length=100)

    class Meta:
        indexes = [
            models.Index(fields=["last_name", "first_name"]),
            models.Index(fields=["first_name"], name="first_name_idx"),
        ]
```

unique_together

Options.unique_together

Use `UniqueConstraint` with the `constraints` option instead.

UniqueConstraint provides more functionality than `unique_together`. `unique_together` may be deprecated in the future.

Sets of field names that, taken together, must be unique:

```
unique_together = [["driver", "restaurant"]]
```

This is a list of lists that must be unique when considered together. It's used in the Django admin and is enforced at the database level (i.e., the appropriate `UNIQUE` statements are included in the `CREATE TABLE` statement).

For convenience, `unique_together` can be a single list when dealing with a single set of fields:

```
unique_together = ["driver", "restaurant"]
```

A *ManyToManyField* cannot be included in `unique_together`. (It's not clear what that would even mean!) If you need to validate uniqueness related to a *ManyToManyField*, try using a signal or an explicit *through* model.

The `ValidationError` raised during model validation when the constraint is violated has the `unique_together` error code.

`index_together`

`Options.index_together`

Sets of field names that, taken together, are indexed:

```
index_together = [
    ["pub_date", "deadline"],
]
```

This list of fields will be indexed together (i.e. the appropriate `CREATE INDEX` statement will be issued.)

For convenience, `index_together` can be a single list when dealing with a single set of fields:

```
index_together = ["pub_date", "deadline"]
```

Deprecated since version 4.2: Use the `indexes` option instead.

`constraints`

`Options.constraints`

A list of `constraints` that you want to define on the model:

```
from django.db import models

class Customer(models.Model):
    age = models.IntegerField()

    class Meta:
        constraints = [
            models.CheckConstraint(check=models.Q(age__gte=18), name="age_gte_18"),
        ]
```

`verbose_name`

`Options.verbose_name`

A human-readable name for the object, singular:

```
verbose_name = "pizza"
```

If this isn't given, Django will use a munged version of the class name: `CamelCase` becomes `camel case`.

`verbose_name_plural`

`Options.verbose_name_plural`

The plural name for the object:

```
verbose_name_plural = "stories"
```

If this isn't given, Django will use `verbose_name + "s"`.

Read-only Meta attributes

`label`

`Options.label`

Representation of the object, returns `app_label.object_name`, e.g. `'polls.Question'`.

`label_lower`

`Options.label_lower`

Representation of the model, returns `app_label.model_name`, e.g. `'polls.question'`.

6.16.9 Model instance reference

This document describes the details of the `Model` API. It builds on the material presented in the [model](#) and [database query](#) guides, so you'll probably want to read and understand those documents before reading this one.

Throughout this reference we'll use the [example blog models](#) presented in the [database query guide](#).

Creating objects

To create a new instance of a model, instantiate it like any other Python class:

```
class Model(**kwargs)
```

The keyword arguments are the names of the fields you've defined on your model. Note that instantiating a model in no way touches your database; for that, you need to *save()*.

Note: You may be tempted to customize the model by overriding the `__init__` method. If you do so, however, take care not to change the calling signature as any change may prevent the model instance from being saved. Rather than overriding `__init__`, try using one of these approaches:

1. Add a classmethod on the model class:

```
from django.db import models

class Book(models.Model):
    title = models.CharField(max_length=100)

    @classmethod
    def create(cls, title):
        book = cls(title=title)
        # do something with the book
        return book

book = Book.create("Pride and Prejudice")
```

2. Add a method on a custom manager (usually preferred):

```
class BookManager(models.Manager):
    def create_book(self, title):
        book = self.create(title=title)
        # do something with the book
        return book

class Book(models.Model):
    title = models.CharField(max_length=100)

    objects = BookManager()

book = Book.objects.create_book("Pride and Prejudice")
```

Customizing model loading

```
classmethod Model.from_db(db, field_names, values)
```

The `from_db()` method can be used to customize model instance creation when loading from the database.

The `db` argument contains the database alias for the database the model is loaded from, `field_names` contains the names of all loaded fields, and `values` contains the loaded values for each field in `field_names`. The `field_names` are in the same order as the `values`. If all of the model's fields are present, then `values` are guaranteed to be in the order `__init__()` expects them. That is, the instance can be created by `cls(*values)`. If any fields are deferred, they won't appear in `field_names`. In that case, assign a value of `django.db.models.DEFERRED` to each of the missing fields.

In addition to creating the new model, the `from_db()` method must set the `adding` and `db` flags in the new instance's `_state` attribute.

Below is an example showing how to record the initial values of fields that are loaded from the database:

```
from django.db.models import DEFERRED

@classmethod
def from_db(cls, db, field_names, values):
    # Default implementation of from_db() (subject to change and could
    # be replaced with super()).
    if len(values) != len(cls._meta.concrete_fields):
        values = list(values)
        values.reverse()
        values = [
            values.pop() if f.attname in field_names else DEFERRED
            for f in cls._meta.concrete_fields
        ]
    instance = cls(*values)
    instance._state.adding = False
    instance._state.db = db
    # customization to store the original field values on the instance
    instance._loaded_values = dict(
        zip(field_names, (value for value in values if value is not DEFERRED))
    )
    return instance

def save(self, *args, **kwargs):
```

(continues on next page)

(continued from previous page)

```

# Check how the current values differ from ._loaded_values. For example,
# prevent changing the creator_id of the model. (This example doesn't
# support cases where 'creator_id' is deferred).
if not self._state.adding and (
    self.creator_id != self._loaded_values["creator_id"]
):
    raise ValueError("Updating the value of creator isn't allowed")
super().save(*args, **kwargs)

```

The example above shows a full `from_db()` implementation to clarify how that is done. In this case it would be possible to use a `super()` call in the `from_db()` method.

Refreshing objects from database

If you delete a field from a model instance, accessing it again reloads the value from the database:

```

>>> obj = MyModel.objects.first()
>>> del obj.field
>>> obj.field  # Loads the field from the database

```

`Model.refresh_from_db(using=None, fields=None)`

`Model.arefresh_from_db(using=None, fields=None)`

Asynchronous version: `arefresh_from_db()`

If you need to reload a model's values from the database, you can use the `refresh_from_db()` method. When this method is called without arguments the following is done:

1. All non-deferred fields of the model are updated to the values currently present in the database.
2. Any cached relations are cleared from the reloaded instance.

Only fields of the model are reloaded from the database. Other database-dependent values such as annotations aren't reloaded. Any `@cached_property` attributes aren't cleared either.

The reloading happens from the database the instance was loaded from, or from the default database if the instance wasn't loaded from the database. The `using` argument can be used to force the database used for reloading.

It is possible to force the set of fields to be loaded by using the `fields` argument.

For example, to test that an `update()` call resulted in the expected update, you could write a test similar to this:

```

def test_update_result(self):
    obj = MyModel.objects.create(val=1)

```

(continues on next page)

(continued from previous page)

```
MyModel.objects.filter(pk=obj.pk).update(val=F("val") + 1)
# At this point obj.val is still 1, but the value in the database
# was updated to 2. The object's updated value needs to be reloaded
# from the database.
obj.refresh_from_db()
self.assertEqual(obj.val, 2)
```

Note that when deferred fields are accessed, the loading of the deferred field's value happens through this method. Thus it is possible to customize the way deferred loading happens. The example below shows how one can reload all of the instance's fields when a deferred field is reloaded:

```
class ExampleModel(models.Model):
    def refresh_from_db(self, using=None, fields=None, **kwargs):
        # fields contains the name of the deferred field to be
        # loaded.
        if fields is not None:
            fields = set(fields)
            deferred_fields = self.get_deferred_fields()
            # If any deferred field is going to be loaded
            if fields.intersection(deferred_fields):
                # then load all of them
                fields = fields.union(deferred_fields)
        super().refresh_from_db(using, fields, **kwargs)
```

`Model.get_deferred_fields()`

A helper method that returns a set containing the attribute names of all those fields that are currently deferred for this model.

`arefresh_from_db()` method was added.

Validating objects

There are four steps involved in validating a model:

1. Validate the model fields - `Model.clean_fields()`
2. Validate the model as a whole - `Model.clean()`
3. Validate the field uniqueness - `Model.validate_unique()`
4. Validate the constraints - `Model.validate_constraints()`

All four steps are performed when you call a model's `full_clean()` method.

When you use a `ModelForm`, the call to `is_valid()` will perform these validation steps for all the fields that are included on the form. See the [ModelForm documentation](#) for more information. You should only need to

call a model's `full_clean()` method if you plan to handle validation errors yourself, or if you have excluded fields from the `ModelForm` that require validation.

Warning: Constraints containing `JSONField` may not raise validation errors as key, index, and path transforms have many database-specific caveats. This may be fully supported later.

You should always check that there are no log messages, in the `django.db.models` logger, like “Got a database error calling `check()` on ...” to confirm it's validated properly.

In older versions, constraints were not checked during the model validation.

```
Model.full_clean(exclude=None, validate_unique=True, validate_constraints=True)
```

This method calls `Model.clean_fields()`, `Model.clean()`, `Model.validate_unique()` (if `validate_unique` is `True`), and `Model.validate_constraints()` (if `validate_constraints` is `True`) in that order and raises a `ValidationError` that has a `message_dict` attribute containing errors from all four stages.

The optional `exclude` argument can be used to provide a set of field names that can be excluded from validation and cleaning. `ModelForm` uses this argument to exclude fields that aren't present on your form from being validated since any errors raised could not be corrected by the user.

Note that `full_clean()` will not be called automatically when you call your model's `save()` method. You'll need to call it manually when you want to run one-step model validation for your own manually created models. For example:

```
from django.core.exceptions import ValidationError

try:
    article.full_clean()
except ValidationError as e:
    # Do something based on the errors contained in e.message_dict.
    # Display them to a user, or handle them programmatically.
    pass
```

The first step `full_clean()` performs is to clean each individual field.

The `validate_constraints` argument was added.

An `exclude` value is now converted to a set rather than a list.

```
Model.clean_fields(exclude=None)
```

This method will validate all fields on your model. The optional `exclude` argument lets you provide a set of field names to exclude from validation. It will raise a `ValidationError` if any fields fail validation.

The second step `full_clean()` performs is to call `Model.clean()`. This method should be overridden to perform custom validation on your model.

`Model.clean()`

This method should be used to provide custom model validation, and to modify attributes on your model if desired. For instance, you could use it to automatically provide a value for a field, or to do validation that requires access to more than a single field:

```
import datetime
from django.core.exceptions import ValidationError
from django.db import models
from django.utils.translation import gettext_lazy as _

class Article(models.Model):
    ...

    def clean(self):
        # Don't allow draft entries to have a pub_date.
        if self.status == "draft" and self.pub_date is not None:
            raise ValidationError(_("Draft entries may not have a publication date."))
        # Set the pub_date for published items if it hasn't been set already.
        if self.status == "published" and self.pub_date is None:
            self.pub_date = datetime.date.today()
```

Note, however, that like `Model.full_clean()`, a model's `clean()` method is not invoked when you call your model's `save()` method.

In the above example, the `ValidationError` exception raised by `Model.clean()` was instantiated with a string, so it will be stored in a special error dictionary key, `NON_FIELD_ERRORS`. This key is used for errors that are tied to the entire model instead of to a specific field:

```
from django.core.exceptions import NON_FIELD_ERRORS, ValidationError

try:
    article.full_clean()
except ValidationError as e:
    non_field_errors = e.message_dict[NON_FIELD_ERRORS]
```

To assign exceptions to a specific field, instantiate the `ValidationError` with a dictionary, where the keys are the field names. We could update the previous example to assign the error to the `pub_date` field:

```
class Article(models.Model):
    ...

    def clean(self):
        # Don't allow draft entries to have a pub_date.
```

(continues on next page)

(continued from previous page)

```

if self.status == "draft" and self.pub_date is not None:
    raise ValidationError(
        {"pub_date": _("Draft entries may not have a publication date.")}
    )
...

```

If you detect errors in multiple fields during `Model.clean()`, you can also pass a dictionary mapping field names to errors:

```

raise ValidationError(
    {
        "title": ValidationError(_("Missing title."), code="required"),
        "pub_date": ValidationError(_("Invalid date."), code="invalid"),
    }
)

```

Then, `full_clean()` will check unique constraints on your model.

How to raise field-specific validation errors if those fields don't appear in a `ModelForm`

You can't raise validation errors in `Model.clean()` for fields that don't appear in a model form (a form may limit its fields using `Meta.fields` or `Meta.exclude`). Doing so will raise a `ValueError` because the validation error won't be able to be associated with the excluded field.

To work around this dilemma, instead override `Model.clean_fields()` as it receives the list of fields that are excluded from validation. For example:

```

class Article(models.Model):
    ...

    def clean_fields(self, exclude=None):
        super().clean_fields(exclude=exclude)
        if self.status == "draft" and self.pub_date is not None:
            if exclude and "status" in exclude:
                raise ValidationError(
                    _("Draft entries may not have a publication date.")
                )
            else:
                raise ValidationError(
                    {
                        "status": _(
                            "Set status to draft if there is not a " "publication date."
                        ),
                    }
                )

```

(continues on next page)

)

`Model.validate_unique(exclude=None)`

This method is similar to `clean_fields()`, but validates uniqueness constraints defined via `Field.unique`, `Field.unique_for_date`, `Field.unique_for_month`, `Field.unique_for_year`, or `Meta.unique_together` on your model instead of individual field values. The optional `exclude` argument allows you to provide a set of field names to exclude from validation. It will raise a `ValidationError` if any fields fail validation.

`UniqueConstraints` defined in the `Meta.constraints` are validated by `Model.validate_constraints()`.

Note that if you provide an `exclude` argument to `validate_unique()`, any `unique_together` constraint involving one of the fields you provided will not be checked.

Finally, `full_clean()` will check any other constraints on your model.

In older versions, `UniqueConstraints` were validated by `validate_unique()`.

`Model.validate_constraints(exclude=None)`

This method validates all constraints defined in `Meta.constraints`. The optional `exclude` argument allows you to provide a set of field names to exclude from validation. It will raise a `ValidationError` if any constraints fail validation.

Saving objects

To save an object back to the database, call `save()`:

`Model.save(force_insert=False, force_update=False, using=DEFAULT_DB_ALIAS, update_fields=None)`

`Model.asave(force_insert=False, force_update=False, using=DEFAULT_DB_ALIAS,
update_fields=None)`

Asynchronous version: `asave()`

For details on using the `force_insert` and `force_update` arguments, see [Forcing an INSERT or UPDATE](#). Details about the `update_fields` argument can be found in the [Specifying which fields to save](#) section.

If you want customized saving behavior, you can override this `save()` method. See [Overriding predefined model methods](#) for more details.

The model save process also has some subtleties; see the sections below.

`asave()` method was added.

Auto-incrementing primary keys

If a model has an *AutoField*—an auto-incrementing primary key—then that auto-incremented value will be calculated and saved as an attribute on your object the first time you call `save()`:

```
>>> b2 = Blog(name="Cheddar Talk", tagline="Thoughts on cheese.")
>>> b2.id # Returns None, because b2 doesn't have an ID yet.
>>> b2.save()
>>> b2.id # Returns the ID of your new object.
```

There's no way to tell what the value of an ID will be before you call `save()`, because that value is calculated by your database, not by Django.

For convenience, each model has an *AutoField* named `id` by default unless you explicitly specify `primary_key=True` on a field in your model. See the documentation for *AutoField* for more details.

The `pk` property

`Model.pk`

Regardless of whether you define a primary key field yourself, or let Django supply one for you, each model will have a property called `pk`. It behaves like a normal attribute on the model, but is actually an alias for whichever attribute is the primary key field for the model. You can read and set this value, just as you would for any other attribute, and it will update the correct field in the model.

Explicitly specifying auto-primary-key values

If a model has an *AutoField* but you want to define a new object's ID explicitly when saving, define it explicitly before saving, rather than relying on the auto-assignment of the ID:

```
>>> b3 = Blog(id=3, name="Cheddar Talk", tagline="Thoughts on cheese.")
>>> b3.id # Returns 3.
>>> b3.save()
>>> b3.id # Returns 3.
```

If you assign auto-primary-key values manually, make sure not to use an already-existing primary-key value! If you create a new object with an explicit primary-key value that already exists in the database, Django will assume you're changing the existing record rather than creating a new one.

Given the above 'Cheddar Talk' blog example, this example would override the previous record in the database:

```
b4 = Blog(id=3, name="Not Cheddar", tagline="Anything but cheese.")
b4.save() # Overrides the previous blog with ID=3!
```

See [How Django knows to UPDATE vs. INSERT](#), below, for the reason this happens.

Explicitly specifying auto-primary-key values is mostly useful for bulk-saving objects, when you're confident you won't have primary-key collision.

If you're using PostgreSQL, the sequence associated with the primary key might need to be updated; see [Manually-specifying values of auto-incrementing primary keys](#).

What happens when you save?

When you save an object, Django performs the following steps:

1. Emit a pre-save signal. The `pre_save` signal is sent, allowing any functions listening for that signal to do something.
2. Preprocess the data. Each field's `pre_save()` method is called to perform any automated data modification that's needed. For example, the date/time fields override `pre_save()` to implement `auto_now_add` and `auto_now`.
3. Prepare the data for the database. Each field's `get_db_prep_save()` method is asked to provide its current value in a data type that can be written to the database.

Most fields don't require data preparation. Simple data types, such as integers and strings, are 'ready to write' as a Python object. However, more complex data types often require some modification.

For example, `DateField` fields use a Python `datetime` object to store data. Databases don't store `datetime` objects, so the field value must be converted into an ISO-compliant date string for insertion into the database.

4. Insert the data into the database. The preprocessed, prepared data is composed into an SQL statement for insertion into the database.
5. Emit a post-save signal. The `post_save` signal is sent, allowing any functions listening for that signal to do something.

How Django knows to UPDATE vs. INSERT

You may have noticed Django database objects use the same `save()` method for creating and changing objects. Django abstracts the need to use `INSERT` or `UPDATE` SQL statements. Specifically, when you call `save()` and the object's primary key attribute does not define a `default`, Django follows this algorithm:

- If the object's primary key attribute is set to a value that evaluates to `True` (i.e., a value other than `None` or the empty string), Django executes an `UPDATE`.
- If the object's primary key attribute is not set or if the `UPDATE` didn't update anything (e.g. if primary key is set to a value that doesn't exist in the database), Django executes an `INSERT`.

If the object's primary key attribute defines a *default* then Django executes an `UPDATE` if it is an existing model instance and primary key is set to a value that exists in the database. Otherwise, Django executes an `INSERT`.

The one gotcha here is that you should be careful not to specify a primary-key value explicitly when saving new objects, if you cannot guarantee the primary-key value is unused. For more on this nuance, see [Explicitly specifying auto-primary-key values](#) above and [Forcing an INSERT or UPDATE](#) below.

In Django 1.5 and earlier, Django did a `SELECT` when the primary key attribute was set. If the `SELECT` found a row, then Django did an `UPDATE`, otherwise it did an `INSERT`. The old algorithm results in one more query in the `UPDATE` case. There are some rare cases where the database doesn't report that a row was updated even if the database contains a row for the object's primary key value. An example is the PostgreSQL `ON UPDATE` trigger which returns `NULL`. In such cases it is possible to revert to the old algorithm by setting the *select_on_save* option to `True`.

Forcing an INSERT or UPDATE

In some rare circumstances, it's necessary to be able to force the *save()* method to perform an SQL `INSERT` and not fall back to doing an `UPDATE`. Or vice-versa: update, if possible, but not insert a new row. In these cases you can pass the *force_insert=True* or *force_update=True* parameters to the *save()* method. Passing both parameters is an error: you cannot both insert and update at the same time!

It should be very rare that you'll need to use these parameters. Django will almost always do the right thing and trying to override that will lead to errors that are difficult to track down. This feature is for advanced use only.

Using *update_fields* will force an update similarly to *force_update*.

Updating attributes based on existing fields

Sometimes you'll need to perform a simple arithmetic task on a field, such as incrementing or decrementing the current value. One way of achieving this is doing the arithmetic in Python like:

```
>>> product = Product.objects.get(name="Venezuelan Beaver Cheese")
>>> product.number_sold += 1
>>> product.save()
```

If the old *number_sold* value retrieved from the database was 10, then the value of 11 will be written back to the database.

The process can be made robust, [avoiding a race condition](#), as well as slightly faster by expressing the update relative to the original field value, rather than as an explicit assignment of a new value. Django provides *F expressions* for performing this kind of relative update. Using *F expressions*, the previous example is expressed as:

```
>>> from django.db.models import F
>>> product = Product.objects.get(name="Venezuelan Beaver Cheese")
>>> product.number_sold = F("number_sold") + 1
>>> product.save()
```

For more details, see the documentation on *F expressions* and their use in update queries.

Specifying which fields to save

If `save()` is passed a list of field names in keyword argument `update_fields`, only the fields named in that list will be updated. This may be desirable if you want to update just one or a few fields on an object. There will be a slight performance benefit from preventing all of the model fields from being updated in the database. For example:

```
product.name = "Name changed again"
product.save(update_fields=["name"])
```

The `update_fields` argument can be any iterable containing strings. An empty `update_fields` iterable will skip the save. A value of `None` will perform an update on all fields.

Specifying `update_fields` will force an update.

When saving a model fetched through deferred model loading (*only()* or *defer()*) only the fields loaded from the DB will get updated. In effect there is an automatic `update_fields` in this case. If you assign or change any deferred field value, the field will be added to the updated fields.

Field.pre_save() and update_fields

If `update_fields` is passed in, only the *pre_save()* methods of the `update_fields` are called. For example, this means that date/time fields with `auto_now=True` will not be updated unless they are included in the `update_fields`.

Deleting objects

```
Model.delete(using=DEFAULT_DB_ALIAS, keep_parents=False)
```

```
Model.adelete(using=DEFAULT_DB_ALIAS, keep_parents=False)
```

Asynchronous version: `adelete()`

Issues an SQL DELETE for the object. This only deletes the object in the database; the Python instance will still exist and will still have data in its fields, except for the primary key set to `None`. This method returns the number of objects deleted and a dictionary with the number of deletions per object type.

For more details, including how to delete objects in bulk, see [Deleting objects](#).

If you want customized deletion behavior, you can override the `delete()` method. See [Overriding predefined model methods](#) for more details.

Sometimes with [multi-table inheritance](#) you may want to delete only a child model's data. Specifying `keep_parents=True` will keep the parent model's data.

`adelete()` method was added.

Pickling objects

When you [pickle](#) a model, its current state is pickled. When you unpickle it, it'll contain the model instance at the moment it was pickled, rather than the data that's currently in the database.

You can't share pickles between versions

Pickles of models are only valid for the version of Django that was used to generate them. If you generate a pickle using Django version N, there is no guarantee that pickle will be readable with Django version N+1. Pickles should not be used as part of a long-term archival strategy.

Since pickle compatibility errors can be difficult to diagnose, such as silently corrupted objects, a `RuntimeWarning` is raised when you try to unpickle a model in a Django version that is different than the one in which it was pickled.

Other model instance methods

A few object methods have special purposes.

`__str__()`

`Model.__str__()`

The `__str__()` method is called whenever you call `str()` on an object. Django uses `str(obj)` in a number of places. Most notably, to display an object in the Django admin site and as the value inserted into a template when it displays an object. Thus, you should always return a nice, human-readable representation of the model from the `__str__()` method.

For example:

```
from django.db import models

class Person(models.Model):
```

(continues on next page)

(continued from previous page)

```
first_name = models.CharField(max_length=50)
last_name = models.CharField(max_length=50)

def __str__(self):
    return f"{self.first_name} {self.last_name}"
```

`__eq__()`

`Model.__eq__()`

The equality method is defined such that instances with the same primary key value and the same concrete class are considered equal, except that instances with a primary key value of `None` aren't equal to anything except themselves. For proxy models, concrete class is defined as the model's first non-proxy parent; for all other models it's simply the model's class.

For example:

```
from django.db import models

class MyModel(models.Model):
    id = models.AutoField(primary_key=True)

class MyProxyModel(MyModel):
    class Meta:
        proxy = True

class MultitableInherited(MyModel):
    pass

# Primary keys compared
MyModel(id=1) == MyModel(id=1)
MyModel(id=1) != MyModel(id=2)

# Primary keys are None
MyModel(id=None) != MyModel(id=None)

# Same instance
instance = MyModel(id=None)
instance == instance

# Proxy model
MyModel(id=1) == MyProxyModel(id=1)
```

(continues on next page)

(continued from previous page)

```
# Multi-table inheritance
MyModel(id=1) != MultitableInherited(id=1)
```

`__hash__()`

`Model.__hash__()`

The `__hash__()` method is based on the instance’s primary key value. It is effectively `hash(obj.pk)`. If the instance doesn’t have a primary key value then a `TypeError` will be raised (otherwise the `__hash__()` method would return different values before and after the instance is saved, but changing the `__hash__()` value of an instance is forbidden in Python).

`get_absolute_url()`

`Model.get_absolute_url()`

Define a `get_absolute_url()` method to tell Django how to calculate the canonical URL for an object. To callers, this method should appear to return a string that can be used to refer to the object over HTTP.

For example:

```
def get_absolute_url(self):
    return "/people/%i/" % self.id
```

While this code is correct and simple, it may not be the most portable way to write this kind of method. The `reverse()` function is usually the best approach.

For example:

```
def get_absolute_url(self):
    from django.urls import reverse

    return reverse("people-detail", kwargs={"pk": self.pk})
```

One place Django uses `get_absolute_url()` is in the admin app. If an object defines this method, the object-editing page will have a “View on site” link that will jump you directly to the object’s public view, as given by `get_absolute_url()`.

Similarly, a couple of other bits of Django, such as the [syndication feed framework](#), use `get_absolute_url()` when it is defined. If it makes sense for your model’s instances to each have a unique URL, you should define `get_absolute_url()`.

Warning: You should avoid building the URL from unvalidated user input, in order to reduce possibilities of link or redirect poisoning:

```
def get_absolute_url(self):  
    return "%s/" % self.name
```

If `self.name` is `/example.com` this returns `//example.com/` which, in turn, is a valid schema relative URL but not the expected `/%2Fexample.com/`.

It's good practice to use `get_absolute_url()` in templates, instead of hard-coding your objects' URLs. For example, this template code is bad:

```
<!-- BAD template code. Avoid! -->  
<a href="/people/{{ object.id }}">{{ object.name }}</a>
```

This template code is much better:

```
<a href="{{ object.get_absolute_url }}">{{ object.name }}</a>
```

The logic here is that if you change the URL structure of your objects, even for something small like correcting a spelling error, you don't want to have to track down every place that the URL might be created. Specify it once, in `get_absolute_url()` and have all your other code call that one place.

Note: The string you return from `get_absolute_url()` must contain only ASCII characters (required by the URI specification, [RFC 3986#section-2](#)) and be URL-encoded, if necessary.

Code and templates calling `get_absolute_url()` should be able to use the result directly without any further processing. You may wish to use the `django.utils.encoding.iri_to_uri()` function to help with this if you are using strings containing characters outside the ASCII range.

Extra instance methods

In addition to `save()`, `delete()`, a model object might have some of the following methods:

`Model.get_F00_display()`

For every field that has `choices` set, the object will have a `get_F00_display()` method, where F00 is the name of the field. This method returns the “human-readable” value of the field.

For example:

```
from django.db import models
```

(continues on next page)

(continued from previous page)

```
class Person(models.Model):
    SHIRT_SIZES = [
        ("S", "Small"),
        ("M", "Medium"),
        ("L", "Large"),
    ]
    name = models.CharField(max_length=60)
    shirt_size = models.CharField(max_length=2, choices=SHIRT_SIZES)
```

```
>>> p = Person(name="Fred Flintstone", shirt_size="L")
>>> p.save()
>>> p.shirt_size
'L'
>>> p.get_shirt_size_display()
'Large'
```

`Model.get_next_by_FOO(**kwargs)`

`Model.get_previous_by_FOO(**kwargs)`

For every *DateField* and *DateTimeField* that does not have *null=True*, the object will have `get_next_by_FOO()` and `get_previous_by_FOO()` methods, where FOO is the name of the field. This returns the next and previous object with respect to the date field, raising a *DoesNotExist* exception when appropriate.

Both of these methods will perform their queries using the default manager for the model. If you need to emulate filtering used by a custom manager, or want to perform one-off custom filtering, both methods also accept optional keyword arguments, which should be in the format described in [Field lookups](#).

Note that in the case of identical date values, these methods will use the primary key as a tie-breaker. This guarantees that no records are skipped or duplicated. That also means you cannot use those methods on unsaved objects.

Overriding extra instance methods

In most cases overriding or inheriting `get_FOO_display()`, `get_next_by_FOO()`, and `get_previous_by_FOO()` should work as expected. Since they are added by the metaclass however, it is not practical to account for all possible inheritance structures. In more complex cases you should override `Field.contribute_to_class()` to set the methods you need.

Other attributes

`_state`

`Model._state`

The `_state` attribute refers to a `ModelState` object that tracks the lifecycle of the model instance.

The `ModelState` object has two attributes: `adding`, a flag which is `True` if the model has not been saved to the database yet, and `db`, a string referring to the database alias the instance was loaded from or saved to.

Newly instantiated instances have `adding=True` and `db=None`, since they are yet to be saved. Instances fetched from a `QuerySet` will have `adding=False` and `db` set to the alias of the associated database.

6.16.10 QuerySet API reference

This document describes the details of the `QuerySet` API. It builds on the material presented in the [model](#) and [database query](#) guides, so you'll probably want to read and understand those documents before reading this one.

Throughout this reference we'll use the [example blog models](#) presented in the [database query guide](#).

When QuerySets are evaluated

Internally, a `QuerySet` can be constructed, filtered, sliced, and generally passed around without actually hitting the database. No database activity actually occurs until you do something to evaluate the queryset.

You can evaluate a `QuerySet` in the following ways:

- Iteration. A `QuerySet` is iterable, and it executes its database query the first time you iterate over it. For example, this will print the headline of all entries in the database:

```
for e in Entry.objects.all():
    print(e.headline)
```

Note: Don't use this if all you want to do is determine if at least one result exists. It's more efficient to use `exists()`.

- Asynchronous iteration. A `QuerySet` can also be iterated over using `async for`:

```
async for e in Entry.objects.all():
    results.append(e)
```

Both synchronous and asynchronous iterators of `QuerySets` share the same underlying cache.

Support for asynchronous iteration was added.

- **Slicing.** As explained in [Limiting QuerySets](#), a `QuerySet` can be sliced, using Python’s array-slicing syntax. Slicing an unevaluated `QuerySet` usually returns another unevaluated `QuerySet`, but Django will execute the database query if you use the “step” parameter of slice syntax, and will return a list. Slicing a `QuerySet` that has been evaluated also returns a list.

Also note that even though slicing an unevaluated `QuerySet` returns another unevaluated `QuerySet`, modifying it further (e.g., adding more filters, or modifying ordering) is not allowed, since that does not translate well into SQL and it would not have a clear meaning either.

- **Pickling/Caching.** See the following section for details of what is involved when [pickling QuerySets](#). The important thing for the purposes of this section is that the results are read from the database.
- **repr().** A `QuerySet` is evaluated when you call `repr()` on it. This is for convenience in the Python interactive interpreter, so you can immediately see your results when using the API interactively.
- **len().** A `QuerySet` is evaluated when you call `len()` on it. This, as you might expect, returns the length of the result list.

Note: If you only need to determine the number of records in the set (and don’t need the actual objects), it’s much more efficient to handle a count at the database level using SQL’s `SELECT COUNT(*)`. Django provides a `count()` method for precisely this reason.

- **list().** Force evaluation of a `QuerySet` by calling `list()` on it. For example:

```
entry_list = list(Entry.objects.all())
```

- **bool().** Testing a `QuerySet` in a boolean context, such as using `bool()`, `or`, `and` or an `if` statement, will cause the query to be executed. If there is at least one result, the `QuerySet` is `True`, otherwise `False`. For example:

```
if Entry.objects.filter(headline="Test"):
    print("There is at least one Entry with the headline Test")
```

Note: If you only want to determine if at least one result exists (and don’t need the actual objects), it’s more efficient to use `exists()`.

Pickling QuerySets

If you [pickle](#) a `QuerySet`, this will force all the results to be loaded into memory prior to pickling. Pickling is usually used as a precursor to caching and when the cached queryset is reloaded, you want the results to already be present and ready for use (reading from the database can take some time, defeating the purpose of caching). This means that when you unpickle a `QuerySet`, it contains the results at the moment it was pickled, rather than the results that are currently in the database.

If you only want to pickle the necessary information to recreate the `QuerySet` from the database at a later time, pickle the `query` attribute of the `QuerySet`. You can then recreate the original `QuerySet` (without any results loaded) using some code like this:

```
>>> import pickle
>>> query = pickle.loads(s) # Assuming 's' is the pickled string.
>>> qs = MyModel.objects.all()
>>> qs.query = query # Restore the original 'query'.
```

The `query` attribute is an opaque object. It represents the internals of the query construction and is not part of the public API. However, it is safe (and fully supported) to pickle and unpickle the attribute's contents as described here.

Restrictions on `QuerySet.values_list()`

If you recreate `QuerySet.values_list()` using the pickled `query` attribute, it will be converted to `QuerySet.values()`:

```
>>> import pickle
>>> qs = Blog.objects.values_list("id", "name")
>>> qs
<QuerySet [(1, 'Beatles Blog')]>
>>> reloaded_qs = Blog.objects.all()
>>> reloaded_qs.query = pickle.loads(pickle.dumps(qs.query))
>>> reloaded_qs
<QuerySet [{'id': 1, 'name': 'Beatles Blog'}]>
```

You can't share pickles between versions

Pickles of `QuerySets` are only valid for the version of Django that was used to generate them. If you generate a pickle using Django version N, there is no guarantee that pickle will be readable with Django version N+1. Pickles should not be used as part of a long-term archival strategy.

Since pickle compatibility errors can be difficult to diagnose, such as silently corrupted objects, a `RuntimeWarning` is raised when you try to unpickle a queryset in a Django version that is different than the one in which it was pickled.

QuerySet API

Here's the formal declaration of a `QuerySet`:

```
class QuerySet(model=None, query=None, using=None, hints=None)
```

Usually when you'll interact with a `QuerySet` you'll use it by [chaining filters](#). To make this work, most `QuerySet` methods return new querysets. These methods are covered in detail later in this section.

The `QuerySet` class has the following public attributes you can use for introspection:

ordered

True if the `QuerySet` is ordered —i.e. has an `order_by()` clause or a default ordering on the model.
False otherwise.

db

The database that will be used if this query is executed now.

Note: The `query` parameter to `QuerySet` exists so that specialized query subclasses can reconstruct internal query state. The value of the parameter is an opaque representation of that query state and is not part of a public API.

Methods that return new QuerySets

Django provides a range of `QuerySet` refinement methods that modify either the types of results returned by the `QuerySet` or the way its SQL query is executed.

Note: These methods do not run database queries, therefore they are safe to run in asynchronous code, and do not have separate asynchronous versions.

filter()

filter(*args, **kwargs)

Returns a new `QuerySet` containing objects that match the given lookup parameters.

The lookup parameters (**kwargs**) should be in the format described in [Field lookups](#) below. Multiple parameters are joined via AND in the underlying SQL statement.

If you need to execute more complex queries (for example, queries with OR statements), you can use `Q objects` (**args**).

exclude()

exclude(*args, **kwargs)

Returns a new `QuerySet` containing objects that do not match the given lookup parameters.

The lookup parameters (**kwargs**) should be in the format described in [Field lookups](#) below. Multiple parameters are joined via AND in the underlying SQL statement, and the whole thing is enclosed in a NOT().

This example excludes all entries whose `pub_date` is later than 2005-1-3 AND whose `headline` is “Hello” :

```
Entry.objects.exclude(pub_date__gt=datetime.date(2005, 1, 3), headline="Hello")
```

In SQL terms, that evaluates to:

```
SELECT ...
WHERE NOT (pub_date > '2005-1-3' AND headline = 'Hello')
```

This example excludes all entries whose `pub_date` is later than 2005-1-3 OR whose headline is “Hello” :

```
Entry.objects.exclude(pub_date__gt=datetime.date(2005, 1, 3)).exclude(headline="Hello")
```

In SQL terms, that evaluates to:

```
SELECT ...
WHERE NOT pub_date > '2005-1-3'
AND NOT headline = 'Hello'
```

Note the second example is more restrictive.

If you need to execute more complex queries (for example, queries with OR statements), you can use `Q` *objects* (`*args`).

`annotate()`

`annotate(*args, **kwargs)`

Annotates each object in the `QuerySet` with the provided list of [query expressions](#). An expression may be a simple value, a reference to a field on the model (or any related models), or an aggregate expression (averages, sums, etc.) that has been computed over the objects that are related to the objects in the `QuerySet`.

Each argument to `annotate()` is an annotation that will be added to each object in the `QuerySet` that is returned.

The aggregation functions that are provided by Django are described in [Aggregation Functions](#) below.

Annotations specified using keyword arguments will use the keyword as the alias for the annotation. Anonymous arguments will have an alias generated for them based upon the name of the aggregate function and the model field that is being aggregated. Only aggregate expressions that reference a single field can be anonymous arguments. Everything else must be a keyword argument.

For example, if you were manipulating a list of blogs, you may want to determine how many entries have been made in each blog:

```
>>> from django.db.models import Count
>>> q = Blog.objects.annotate(Count("entry"))
# The name of the first blog
```

(continues on next page)

(continued from previous page)

```
>>> q[0].name
'Blogasaurus'
# The number of entries on the first blog
>>> q[0].entry__count
42
```

The `Blog` model doesn't define an `entry__count` attribute by itself, but by using a keyword argument to specify the aggregate function, you can control the name of the annotation:

```
>>> q = Blog.objects.annotate(number_of_entries=Count("entry"))
# The number of entries on the first blog, using the name provided
>>> q[0].number_of_entries
42
```

For an in-depth discussion of aggregation, see [the topic guide on Aggregation](#).

`alias()`

`alias(*args, **kwargs)`

Same as `annotate()`, but instead of annotating objects in the `QuerySet`, saves the expression for later reuse with other `QuerySet` methods. This is useful when the result of the expression itself is not needed but it is used for filtering, ordering, or as a part of a complex expression. Not selecting the unused value removes redundant work from the database which should result in better performance.

For example, if you want to find blogs with more than 5 entries, but are not interested in the exact number of entries, you could do this:

```
>>> from django.db.models import Count
>>> blogs = Blog.objects.alias(entries=Count("entry")).filter(entries__gt=5)
```

`alias()` can be used in conjunction with `annotate()`, `exclude()`, `filter()`, `order_by()`, and `update()`. To use aliased expression with other methods (e.g. `aggregate()`), you must promote it to an annotation:

```
Blog.objects.alias(entries=Count("entry")).annotate(
    entries=F("entries"),
).aggregate(Sum("entries"))
```

`filter()` and `order_by()` can take expressions directly, but expression construction and usage often does not happen in the same place (for example, `QuerySet` method creates expressions, for later use in views). `alias()` allows building complex expressions incrementally, possibly spanning multiple methods and modules, refer to the expression parts by their aliases and only use `annotate()` for the final result.

```
order_by()
```

```
order_by(*fields)
```

By default, results returned by a `QuerySet` are ordered by the ordering tuple given by the `ordering` option in the model's `Meta`. You can override this on a per-`QuerySet` basis by using the `order_by` method.

Example:

```
Entry.objects.filter(pub_date__year=2005).order_by("-pub_date", "headline")
```

The result above will be ordered by `pub_date` descending, then by `headline` ascending. The negative sign in front of `"-pub_date"` indicates descending order. Ascending order is implied. To order randomly, use `"?"`, like so:

```
Entry.objects.order_by("?")
```

Note: `order_by('?')` queries may be expensive and slow, depending on the database backend you're using.

To order by a field in a different model, use the same syntax as when you are querying across model relations. That is, the name of the field, followed by a double underscore (`__`), followed by the name of the field in the new model, and so on for as many models as you want to join. For example:

```
Entry.objects.order_by("blog__name", "headline")
```

If you try to order by a field that is a relation to another model, Django will use the default ordering on the related model, or order by the related model's primary key if there is no `Meta.ordering` specified. For example, since the `Blog` model has no default ordering specified:

```
Entry.objects.order_by("blog")
```

...is identical to:

```
Entry.objects.order_by("blog__id")
```

If `Blog` had `ordering = ['name']`, then the first queryset would be identical to:

```
Entry.objects.order_by("blog__name")
```

You can also order by [query expressions](#) by calling `asc()` or `desc()` on the expression:

```
Entry.objects.order_by(Coalesce("summary", "headline").desc())
```

`asc()` and `desc()` have arguments (`nulls_first` and `nulls_last`) that control how null values are sorted.

Be cautious when ordering by fields in related models if you are also using `distinct()`. See the note in [distinct\(\)](#) for an explanation of how related model ordering can change the expected results.

Note: It is permissible to specify a multi-valued field to order the results by (for example, a *ManyToManyField* field, or the reverse relation of a *ForeignKey* field).

Consider this case:

```
class Event(Model):
    parent = models.ForeignKey(
        "self",
        on_delete=models.CASCADE,
        related_name="children",
    )
    date = models.DateField()

Event.objects.order_by("children__date")
```

Here, there could potentially be multiple ordering data for each `Event`; each `Event` with multiple `children` will be returned multiple times into the new `QuerySet` that `order_by()` creates. In other words, using `order_by()` on the `QuerySet` could return more items than you were working on to begin with - which is probably neither expected nor useful.

Thus, take care when using multi-valued field to order the results. If you can be sure that there will only be one ordering piece of data for each of the items you're ordering, this approach should not present problems. If not, make sure the results are what you expect.

There's no way to specify whether ordering should be case sensitive. With respect to case-sensitivity, Django will order results however your database backend normally orders them.

You can order by a field converted to lowercase with *Lower* which will achieve case-consistent ordering:

```
Entry.objects.order_by(Lower("headline").desc())
```

If you don't want any ordering to be applied to a query, not even the default ordering, call `order_by()` with no parameters.

You can tell if a query is ordered or not by checking the `QuerySet.ordered` attribute, which will be `True` if the `QuerySet` has been ordered in any way.

Each `order_by()` call will clear any previous ordering. For example, this query will be ordered by `pub_date` and not `headline`:

```
Entry.objects.order_by("headline").order_by("pub_date")
```

Warning: Ordering is not a free operation. Each field you add to the ordering incurs a cost to your database. Each foreign key you add will implicitly include all of its default orderings as well.

If a query doesn't have an ordering specified, results are returned from the database in an unspecified order. A particular ordering is guaranteed only when ordering by a set of fields that uniquely identify each object in the results. For example, if a `name` field isn't unique, ordering by it won't guarantee objects with the same name always appear in the same order.

`reverse()`

`reverse()`

Use the `reverse()` method to reverse the order in which a queryset's elements are returned. Calling `reverse()` a second time restores the ordering back to the normal direction.

To retrieve the “last” five items in a queryset, you could do this:

```
my_queryset.reverse()[:5]
```

Note that this is not quite the same as slicing from the end of a sequence in Python. The above example will return the last item first, then the penultimate item and so on. If we had a Python sequence and looked at `seq[-5:]`, we would see the fifth-last item first. Django doesn't support that mode of access (slicing from the end), because it's not possible to do it efficiently in SQL.

Also, note that `reverse()` should generally only be called on a `QuerySet` which has a defined ordering (e.g., when querying against a model which defines a default ordering, or when using `order_by()`). If no such ordering is defined for a given `QuerySet`, calling `reverse()` on it has no real effect (the ordering was undefined prior to calling `reverse()`, and will remain undefined afterward).

`distinct()`

`distinct(*fields)`

Returns a new `QuerySet` that uses `SELECT DISTINCT` in its SQL query. This eliminates duplicate rows from the query results.

By default, a `QuerySet` will not eliminate duplicate rows. In practice, this is rarely a problem, because simple queries such as `Blog.objects.all()` don't introduce the possibility of duplicate result rows. However, if your query spans multiple tables, it's possible to get duplicate results when a `QuerySet` is evaluated. That's when you'd use `distinct()`.

Note: Any fields used in an `order_by()` call are included in the SQL `SELECT` columns. This can sometimes lead to unexpected results when used in conjunction with `distinct()`. If you order by fields from a related

model, those fields will be added to the selected columns and they may make otherwise duplicate rows appear to be distinct. Since the extra columns don't appear in the returned results (they are only there to support ordering), it sometimes looks like non-distinct results are being returned.

Similarly, if you use a `values()` query to restrict the columns selected, the columns used in any `order_by()` (or default model ordering) will still be involved and may affect uniqueness of the results.

The moral here is that if you are using `distinct()` be careful about ordering by related models. Similarly, when using `distinct()` and `values()` together, be careful when ordering by fields not in the `values()` call.

On PostgreSQL only, you can pass positional arguments (`*fields`) in order to specify the names of fields to which the `DISTINCT` should apply. This translates to a `SELECT DISTINCT ON` SQL query. Here's the difference. For a normal `distinct()` call, the database compares each field in each row when determining which rows are distinct. For a `distinct()` call with specified field names, the database will only compare the specified field names.

Note: When you specify field names, you must provide an `order_by()` in the `QuerySet`, and the fields in `order_by()` must start with the fields in `distinct()`, in the same order.

For example, `SELECT DISTINCT ON (a)` gives you the first row for each value in column `a`. If you don't specify an order, you'll get some arbitrary row.

Examples (those after the first will only work on PostgreSQL):

```
>>> Author.objects.distinct()
[...]

>>> Entry.objects.order_by("pub_date").distinct("pub_date")
[...]

>>> Entry.objects.order_by("blog").distinct("blog")
[...]

>>> Entry.objects.order_by("author", "pub_date").distinct("author", "pub_date")
[...]

>>> Entry.objects.order_by("blog__name", "mod_date").distinct("blog__name", "mod_date")
[...]

>>> Entry.objects.order_by("author", "pub_date").distinct("author")
[...]
```

Note: Keep in mind that `order_by()` uses any default related model ordering that has been defined. You

might have to explicitly order by the relation `_id` or referenced field to make sure the `DISTINCT ON` expressions match those at the beginning of the `ORDER BY` clause. For example, if the `Blog` model defined an *ordering* by name:

```
Entry.objects.order_by("blog").distinct("blog")
```

...wouldn't work because the query would be ordered by `blog__name` thus mismatching the `DISTINCT ON` expression. You'd have to explicitly order by the relation `_id` field (`blog_id` in this case) or the referenced one (`blog__pk`) to make sure both expressions match.

`values()`

`values(*fields, **expressions)`

Returns a `QuerySet` that returns dictionaries, rather than model instances, when used as an iterable.

Each of those dictionaries represents an object, with the keys corresponding to the attribute names of model objects.

This example compares the dictionaries of `values()` with the normal model objects:

```
# This list contains a Blog object.
>>> Blog.objects.filter(name__startswith="Beatles")
<QuerySet [ <Blog: Beatles Blog> ]>

# This list contains a dictionary.
>>> Blog.objects.filter(name__startswith="Beatles").values()
<QuerySet [ {'id': 1, 'name': 'Beatles Blog', 'tagline': 'All the latest Beatles news.'} ]>
```

The `values()` method takes optional positional arguments, `*fields`, which specify field names to which the `SELECT` should be limited. If you specify the fields, each dictionary will contain only the field keys/values for the fields you specify. If you don't specify the fields, each dictionary will contain a key and value for every field in the database table.

Example:

```
>>> Blog.objects.values()
<QuerySet [ {'id': 1, 'name': 'Beatles Blog', 'tagline': 'All the latest Beatles news.'} ]>
>>> Blog.objects.values("id", "name")
<QuerySet [ {'id': 1, 'name': 'Beatles Blog'} ]>
```

The `values()` method also takes optional keyword arguments, `**expressions`, which are passed through to *annotate()*:

```
>>> from django.db.models.functions import Lower
>>> Blog.objects.values(lower_name=Lower("name"))
<QuerySet [{'lower_name': 'beatles blog'}]>
```

You can use built-in and [custom lookups](#) in ordering. For example:

```
>>> from django.db.models import CharField
>>> from django.db.models.functions import Lower
>>> CharField.register_lookup(Lower)
>>> Blog.objects.values("name__lower")
<QuerySet [{'name__lower': 'beatles blog'}]>
```

An aggregate within a `values()` clause is applied before other arguments within the same `values()` clause. If you need to group by another value, add it to an earlier `values()` clause instead. For example:

```
>>> from django.db.models import Count
>>> Blog.objects.values("entry__authors", entries=Count("entry"))
<QuerySet [{'entry__authors': 1, 'entries': 20}, {'entry__authors': 1, 'entries': 13}]>
>>> Blog.objects.values("entry__authors").annotate(entries=Count("entry"))
<QuerySet [{'entry__authors': 1, 'entries': 33}]>
```

A few subtleties that are worth mentioning:

- If you have a field called `foo` that is a *ForeignKey*, the default `values()` call will return a dictionary key called `foo_id`, since this is the name of the hidden model attribute that stores the actual value (the `foo` attribute refers to the related model). When you are calling `values()` and passing in field names, you can pass in either `foo` or `foo_id` and you will get back the same thing (the dictionary key will match the field name you passed in).

For example:

```
>>> Entry.objects.values()
<QuerySet [{'blog_id': 1, 'headline': 'First Entry', ...}, ...]>

>>> Entry.objects.values("blog")
<QuerySet [{'blog': 1}, ...]>

>>> Entry.objects.values("blog_id")
<QuerySet [{'blog_id': 1}, ...]>
```

- When using `values()` together with *distinct()*, be aware that ordering can affect the results. See the note in *distinct()* for details.
- If you use a `values()` clause after an *extra()* call, any fields defined by a `select` argument in the *extra()* must be explicitly included in the `values()` call. Any *extra()* call made after a `values()` call will have its extra selected fields ignored.

- Calling `only()` and `defer()` after `values()` doesn't make sense, so doing so will raise a `TypeError`.
- Combining transforms and aggregates requires the use of two `annotate()` calls, either explicitly or as keyword arguments to `values()`. As above, if the transform has been registered on the relevant field type the first `annotate()` can be omitted, thus the following examples are equivalent:

```
>>> from django.db.models import CharField, Count
>>> from django.db.models.functions import Lower
>>> CharField.register_lookup(Lower)
>>> Blog.objects.values("entry__authors__name__lower").annotate(entries=Count("entry"))
<QuerySet [{'entry__authors__name__lower': 'test author', 'entries': 33}]>
>>> Blog.objects.values(entry__authors__name__lower=Lower("entry__authors__name")).annotate(
...     entries=Count("entry")
... )
<QuerySet [{'entry__authors__name__lower': 'test author', 'entries': 33}]>
>>> Blog.objects.annotate(entry__authors__name__lower=Lower("entry__authors__name")).values(
...     "entry__authors__name__lower"
... ).annotate(entries=Count("entry"))
<QuerySet [{'entry__authors__name__lower': 'test author', 'entries': 33}]>
```

It is useful when you know you're only going to need values from a small number of the available fields and you won't need the functionality of a model instance object. It's more efficient to select only the fields you need to use.

Finally, note that you can call `filter()`, `order_by()`, etc. after the `values()` call, that means that these two calls are identical:

```
Blog.objects.values().order_by("id")
Blog.objects.order_by("id").values()
```

The people who made Django prefer to put all the SQL-affecting methods first, followed (optionally) by any output-affecting methods (such as `values()`), but it doesn't really matter. This is your chance to really flaunt your individualism.

You can also refer to fields on related models with reverse relations through `OneToOneField`, `ForeignKey` and `ManyToManyField` attributes:

```
>>> Blog.objects.values("name", "entry__headline")
<QuerySet [{'name': 'My blog', 'entry__headline': 'An entry'},
 {'name': 'My blog', 'entry__headline': 'Another entry'}, ...]>
```

Warning: Because *ManyToManyField* attributes and reverse relations can have multiple related rows, including these can have a multiplier effect on the size of your result set. This will be especially pronounced if you include multiple such fields in your `values()` query, in which case all possible combinations will

be returned.

Special values for `JSONField` on SQLite

Due to the way the `JSON_EXTRACT` and `JSON_TYPE` SQL functions are implemented on SQLite, and lack of the `BOOLEAN` data type, `values()` will return `True`, `False`, and `None` instead of `"true"`, `"false"`, and `"null"` strings for *JSONField* key transforms.

`values_list()`

`values_list(*fields, flat=False, named=False)`

This is similar to `values()` except that instead of returning dictionaries, it returns tuples when iterated over. Each tuple contains the value from the respective field or expression passed into the `values_list()` call — so the first item is the first field, etc. For example:

```
>>> Entry.objects.values_list("id", "headline")
<QuerySet [(1, 'First entry'), ...]>
>>> from django.db.models.functions import Lower
>>> Entry.objects.values_list("id", Lower("headline"))
<QuerySet [(1, 'first entry'), ...]>
```

If you only pass in a single field, you can also pass in the `flat` parameter. If `True`, this will mean the returned results are single values, rather than one-tuples. An example should make the difference clearer:

```
>>> Entry.objects.values_list("id").order_by("id")
<QuerySet [(1,), (2,), (3,), ...]>

>>> Entry.objects.values_list("id", flat=True).order_by("id")
<QuerySet [1, 2, 3, ...]>
```

It is an error to pass in `flat` when there is more than one field.

You can pass `named=True` to get results as a `namedtuple()`:

```
>>> Entry.objects.values_list("id", "headline", named=True)
<QuerySet [Row(id=1, headline='First entry'), ...]>
```

Using a named tuple may make use of the results more readable, at the expense of a small performance penalty for transforming the results into a named tuple.

If you don't pass any values to `values_list()`, it will return all the fields in the model, in the order they were declared.

A common need is to get a specific field value of a certain model instance. To achieve that, use `values_list()` followed by a `get()` call:

```
>>> Entry.objects.values_list("headline", flat=True).get(pk=1)
'First entry'
```

`values()` and `values_list()` are both intended as optimizations for a specific use case: retrieving a subset of data without the overhead of creating a model instance. This metaphor falls apart when dealing with many-to-many and other multivalued relations (such as the one-to-many relation of a reverse foreign key) because the “one row, one object” assumption doesn’t hold.

For example, notice the behavior when querying across a *ManyToManyField*:

```
>>> Author.objects.values_list("name", "entry__headline")
<QuerySet [(('Noam Chomsky', 'Impressions of Gaza'),
  ('George Orwell', 'Why Socialists Do Not Believe in Fun'),
  ('George Orwell', 'In Defence of English Cooking'),
  ('Don Quixote', None))]>
```

Authors with multiple entries appear multiple times and authors without any entries have `None` for the entry headline.

Similarly, when querying a reverse foreign key, `None` appears for entries not having any author:

```
>>> Entry.objects.values_list("authors")
<QuerySet [(('Noam Chomsky',), ('George Orwell',), (None,))]>
```

Special values for `JSONField` on SQLite

Due to the way the `JSON_EXTRACT` and `JSON_TYPE` SQL functions are implemented on SQLite, and lack of the `BOOLEAN` data type, `values_list()` will return `True`, `False`, and `None` instead of `"true"`, `"false"`, and `"null"` strings for *JSONField* key transforms.

`dates()`

`dates(field, kind, order='ASC')`

Returns a `QuerySet` that evaluates to a list of `datetime.date` objects representing all available dates of a particular kind within the contents of the `QuerySet`.

`field` should be the name of a `DateField` of your model. `kind` should be either `"year"`, `"month"`, `"week"`, or `"day"`. Each `datetime.date` object in the result list is “truncated” to the given type.

- `"year"` returns a list of all distinct year values for the field.

- "month" returns a list of all distinct year/month values for the field.
- "week" returns a list of all distinct year/week values for the field. All dates will be a Monday.
- "day" returns a list of all distinct year/month/day values for the field.

order, which defaults to 'ASC', should be either 'ASC' or 'DESC'. This specifies how to order the results.

Examples:

```
>>> Entry.objects.dates("pub_date", "year")
[datetime.date(2005, 1, 1)]
>>> Entry.objects.dates("pub_date", "month")
[datetime.date(2005, 2, 1), datetime.date(2005, 3, 1)]
>>> Entry.objects.dates("pub_date", "week")
[datetime.date(2005, 2, 14), datetime.date(2005, 3, 14)]
>>> Entry.objects.dates("pub_date", "day")
[datetime.date(2005, 2, 20), datetime.date(2005, 3, 20)]
>>> Entry.objects.dates("pub_date", "day", order="DESC")
[datetime.date(2005, 3, 20), datetime.date(2005, 2, 20)]
>>> Entry.objects.filter(headline__contains="Lennon").dates("pub_date", "day")
[datetime.date(2005, 3, 20)]
```

`datetimes()`

`datetimes(field_name, kind, order='ASC', tzinfo=None, is_dst=None)`

Returns a `QuerySet` that evaluates to a list of `datetime.datetime` objects representing all available dates of a particular kind within the contents of the `QuerySet`.

`field_name` should be the name of a `DateTimeField` of your model.

`kind` should be either "year", "month", "week", "day", "hour", "minute", or "second". Each `datetime.datetime` object in the result list is “truncated” to the given type.

`order`, which defaults to 'ASC', should be either 'ASC' or 'DESC'. This specifies how to order the results.

`tzinfo` defines the time zone to which datetimes are converted prior to truncation. Indeed, a given datetime has different representations depending on the time zone in use. This parameter must be a `datetime.tzinfo` object. If it's `None`, Django uses the [current time zone](#). It has no effect when `USE_TZ` is `False`.

`is_dst` indicates whether or not `pytz` should interpret nonexistent and ambiguous datetimes in daylight saving time. By default (when `is_dst=None`), `pytz` raises an exception for such datetimes.

Deprecated since version 4.0: The `is_dst` parameter is deprecated and will be removed in Django 5.0.

Note: This function performs time zone conversions directly in the database. As a consequence, your database must be able to interpret the value of `tzinfo.tzname(None)`. This translates into the following

requirements:

- SQLite: no requirements. Conversions are performed in Python.
 - PostgreSQL: no requirements (see [Time Zones](#)).
 - Oracle: no requirements (see [Choosing a Time Zone File](#)).
 - MySQL: load the time zone tables with `mysql_tzinfo_to_sql`.
-

`none()`

`none()`

Calling `none()` will create a queryset that never returns any objects and no query will be executed when accessing the results. A `qs.none()` queryset is an instance of `EmptyQuerySet`.

Examples:

```
>>> Entry.objects.none()
<QuerySet []>
>>> from django.db.models.query import EmptyQuerySet
>>> isinstance(Entry.objects.none(), EmptyQuerySet)
True
```

`all()`

`all()`

Returns a copy of the current `QuerySet` (or `QuerySet` subclass). This can be useful in situations where you might want to pass in either a model manager or a `QuerySet` and do further filtering on the result. After calling `all()` on either object, you'll definitely have a `QuerySet` to work with.

When a `QuerySet` is [evaluated](#), it typically caches its results. If the data in the database might have changed since a `QuerySet` was evaluated, you can get updated results for the same query by calling `all()` on a previously evaluated `QuerySet`.

`union()`

`union(*other_qs, all=False)`

Uses SQL's UNION operator to combine the results of two or more `QuerySets`. For example:

```
>>> qs1.union(qs2, qs3)
```

The `UNION` operator selects only distinct values by default. To allow duplicate values, use the `all=True` argument.

`union()`, `intersection()`, and `difference()` return model instances of the type of the first `QuerySet` even if the arguments are `QuerySets` of other models. Passing different models works as long as the `SELECT` list is the same in all `QuerySets` (at least the types, the names don't matter as long as the types are in the same order). In such cases, you must use the column names from the first `QuerySet` in `QuerySet` methods applied to the resulting `QuerySet`. For example:

```
>>> qs1 = Author.objects.values_list("name")
>>> qs2 = Entry.objects.values_list("headline")
>>> qs1.union(qs2).order_by("name")
```

In addition, only `LIMIT`, `OFFSET`, `COUNT(*)`, `ORDER BY`, and specifying columns (i.e. slicing, `count()`, `exists()`, `order_by()`, and `values()/values_list()`) are allowed on the resulting `QuerySet`. Further, databases place restrictions on what operations are allowed in the combined queries. For example, most databases don't allow `LIMIT` or `OFFSET` in the combined queries.

`intersection()`

`intersection(*other_qs)`

Uses SQL's `INTERSECT` operator to return the shared elements of two or more `QuerySets`. For example:

```
>>> qs1.intersection(qs2, qs3)
```

See `union()` for some restrictions.

`difference()`

`difference(*other_qs)`

Uses SQL's `EXCEPT` operator to keep only elements present in the `QuerySet` but not in some other `QuerySets`. For example:

```
>>> qs1.difference(qs2, qs3)
```

See `union()` for some restrictions.

```
select_related()
```

```
select_related(*fields)
```

Returns a `QuerySet` that will “follow” foreign-key relationships, selecting additional related-object data when it executes its query. This is a performance booster which results in a single more complex query but means later use of foreign-key relationships won’t require database queries.

The following examples illustrate the difference between plain lookups and `select_related()` lookups. Here’s standard lookup:

```
# Hits the database.
e = Entry.objects.get(id=5)

# Hits the database again to get the related Blog object.
b = e.blog
```

And here’s `select_related` lookup:

```
# Hits the database.
e = Entry.objects.select_related("blog").get(id=5)

# Doesn't hit the database, because e.blog has been prepopulated
# in the previous query.
b = e.blog
```

You can use `select_related()` with any queryset of objects:

```
from django.utils import timezone

# Find all the blogs with entries scheduled to be published in the future.
blogs = set()

for e in Entry.objects.filter(pub_date__gt=timezone.now()).select_related("blog"):
    # Without select_related(), this would make a database query for each
    # loop iteration in order to fetch the related blog for each entry.
    blogs.add(e.blog)
```

The order of `filter()` and `select_related()` chaining isn’t important. These querysets are equivalent:

```
Entry.objects.filter(pub_date__gt=timezone.now()).select_related("blog")
Entry.objects.select_related("blog").filter(pub_date__gt=timezone.now())
```

You can follow foreign keys in a similar way to querying them. If you have the following models:

```

from django.db import models

class City(models.Model):
    # ...
    pass

class Person(models.Model):
    # ...
    hometown = models.ForeignKey(
        City,
        on_delete=models.SET_NULL,
        blank=True,
        null=True,
    )

class Book(models.Model):
    # ...
    author = models.ForeignKey(Person, on_delete=models.CASCADE)

```

... then a call to `Book.objects.select_related('author__hometown').get(id=4)` will cache the related `Person` and the related `City`:

```

# Hits the database with joins to the author and hometown tables.
b = Book.objects.select_related("author__hometown").get(id=4)
p = b.author # Doesn't hit the database.
c = p.hometown # Doesn't hit the database.

# Without select_related()...
b = Book.objects.get(id=4) # Hits the database.
p = b.author # Hits the database.
c = p.hometown # Hits the database.

```

You can refer to any *ForeignKey* or *OneToOneField* relation in the list of fields passed to `select_related()`.

You can also refer to the reverse direction of a *OneToOneField* in the list of fields passed to `select_related`—that is, you can traverse a *OneToOneField* back to the object on which the field is defined. Instead of specifying the field name, use the *related_name* for the field on the related object.

There may be some situations where you wish to call `select_related()` with a lot of related objects, or where you don't know all of the relations. In these cases it is possible to call `select_related()` with no arguments. This will follow all non-null foreign keys it can find - nullable foreign keys must be specified. This is not recommended in most cases as it is likely to make the underlying query more complex, and return

more data, than is actually needed.

If you need to clear the list of related fields added by past calls of `select_related` on a `QuerySet`, you can pass `None` as a parameter:

```
>>> without_relations = queryset.select_related(None)
```

Chaining `select_related` calls works in a similar way to other methods - that is that `select_related('foo', 'bar')` is equivalent to `select_related('foo').select_related('bar')`.

`prefetch_related()`

`prefetch_related(*lookups)`

Returns a `QuerySet` that will automatically retrieve, in a single batch, related objects for each of the specified lookups.

This has a similar purpose to `select_related`, in that both are designed to stop the deluge of database queries that is caused by accessing related objects, but the strategy is quite different.

`select_related` works by creating an SQL join and including the fields of the related object in the `SELECT` statement. For this reason, `select_related` gets the related objects in the same database query. However, to avoid the much larger result set that would result from joining across a ‘many’ relationship, `select_related` is limited to single-valued relationships - foreign key and one-to-one.

`prefetch_related`, on the other hand, does a separate lookup for each relationship, and does the ‘joining’ in Python. This allows it to prefetch many-to-many and many-to-one objects, which cannot be done using `select_related`, in addition to the foreign key and one-to-one relationships that are supported by `select_related`. It also supports prefetching of *GenericRelation* and *GenericForeignKey*, however, it must be restricted to a homogeneous set of results. For example, prefetching objects referenced by a *GenericForeignKey* is only supported if the query is restricted to one `ContentType`.

For example, suppose you have these models:

```
from django.db import models

class Topping(models.Model):
    name = models.CharField(max_length=30)

class Pizza(models.Model):
    name = models.CharField(max_length=50)
    toppings = models.ManyToManyField(Topping)

    def __str__(self):
```

(continues on next page)

(continued from previous page)

```
return "%s (%s)" % (
    self.name,
    ", ".join(topping.name for topping in self.toppings.all()),
)
```

and run:

```
>>> Pizza.objects.all()
["Hawaiian (ham, pineapple)", "Seafood (prawns, smoked salmon)"...
```

The problem with this is that every time `Pizza.__str__()` asks for `self.toppings.all()` it has to query the database, so `Pizza.objects.all()` will run a query on the Toppings table for every item in the Pizza `QuerySet`.

We can reduce to just two queries using `prefetch_related`:

```
>>> Pizza.objects.prefetch_related('toppings')
```

This implies a `self.toppings.all()` for each `Pizza`; now each time `self.toppings.all()` is called, instead of having to go to the database for the items, it will find them in a prefetched `QuerySet` cache that was populated in a single query.

That is, all the relevant toppings will have been fetched in a single query, and used to make `QuerySets` that have a pre-filled cache of the relevant results; these `QuerySets` are then used in the `self.toppings.all()` calls.

The additional queries in `prefetch_related()` are executed after the `QuerySet` has begun to be evaluated and the primary query has been executed.

If you have an iterable of model instances, you can prefetch related attributes on those instances using the `prefetch_related_objects()` function.

Note that the result cache of the primary `QuerySet` and all specified related objects will then be fully loaded into memory. This changes the typical behavior of `QuerySets`, which normally try to avoid loading all objects into memory before they are needed, even after a query has been executed in the database.

Note: Remember that, as always with `QuerySets`, any subsequent chained methods which imply a different database query will ignore previously cached results, and retrieve data using a fresh database query. So, if you write the following:

```
>>> pizzas = Pizza.objects.prefetch_related('toppings')
>>> [list(pizza.toppings.filter(spicy=True)) for pizza in pizzas]
```

...then the fact that `pizza.toppings.all()` has been prefetched will not help you. The `prefetch_related('toppings')` implied `pizza.toppings.all()`, but `pizza.toppings.filter()` is a

new and different query. The prefetched cache can't help here; in fact it hurts performance, since you have done a database query that you haven't used. So use this feature with caution!

Also, if you call the database-altering methods `add()`, `remove()`, `clear()` or `set()`, on *related managers*, any prefetched cache for the relation will be cleared.

You can also use the normal join syntax to do related fields of related fields. Suppose we have an additional model to the example above:

```
class Restaurant(models.Model):
    pizzas = models.ManyToManyField(Pizza, related_name="restaurants")
    best_pizza = models.ForeignKey(
        Pizza, related_name="championed_by", on_delete=models.CASCADE
    )
```

The following are all legal:

```
>>> Restaurant.objects.prefetch_related("pizzas__toppings")
```

This will prefetch all pizzas belonging to restaurants, and all toppings belonging to those pizzas. This will result in a total of 3 database queries - one for the restaurants, one for the pizzas, and one for the toppings.

```
>>> Restaurant.objects.prefetch_related("best_pizza__toppings")
```

This will fetch the best pizza and all the toppings for the best pizza for each restaurant. This will be done in 3 database queries - one for the restaurants, one for the 'best pizzas', and one for the toppings.

The `best_pizza` relationship could also be fetched using `select_related` to reduce the query count to 2:

```
>>> Restaurant.objects.select_related("best_pizza").prefetch_related("best_pizza__toppings")
```

Since the prefetch is executed after the main query (which includes the joins needed by `select_related`), it is able to detect that the `best_pizza` objects have already been fetched, and it will skip fetching them again.

Chaining `prefetch_related` calls will accumulate the lookups that are prefetched. To clear any `prefetch_related` behavior, pass `None` as a parameter:

```
>>> non_prefetched = qs.prefetch_related(None)
```

One difference to note when using `prefetch_related` is that objects created by a query can be shared between the different objects that they are related to i.e. a single Python model instance can appear at more than one point in the tree of objects that are returned. This will normally happen with foreign key relationships. Typically this behavior will not be a problem, and will in fact save both memory and CPU time.

While `prefetch_related` supports prefetching `GenericForeignKey` relationships, the number of queries will depend on the data. Since a `GenericForeignKey` can reference data in multiple tables, one query per ta-

ble referenced is needed, rather than one query for all the items. There could be additional queries on the `ContentType` table if the relevant rows have not already been fetched.

`prefetch_related` in most cases will be implemented using an SQL query that uses the ‘IN’ operator. This means that for a large `QuerySet` a large ‘IN’ clause could be generated, which, depending on the database, might have performance problems of its own when it comes to parsing or executing the SQL query. Always profile for your use case!

If you use `iterator()` to run the query, `prefetch_related()` calls will only be observed if a value for `chunk_size` is provided.

You can use the *Prefetch* object to further control the prefetch operation.

In its simplest form *Prefetch* is equivalent to the traditional string based lookups:

```
>>> from django.db.models import Prefetch
>>> Restaurant.objects.prefetch_related(Prefetch('pizzas__toppings'))
```

You can provide a custom queryset with the optional `queryset` argument. This can be used to change the default ordering of the queryset:

```
>>> Restaurant.objects.prefetch_related(
...     Prefetch('pizzas__toppings', queryset=Toppings.objects.order_by('name')))
```

Or to call *select_related()* when applicable to reduce the number of queries even further:

```
>>> Pizza.objects.prefetch_related(
...     Prefetch('restaurants', queryset=Restaurant.objects.select_related('best_pizza')))
```

You can also assign the prefetched result to a custom attribute with the optional `to_attr` argument. The result will be stored directly in a list.

This allows prefetching the same relation multiple times with a different `QuerySet`; for instance:

```
>>> vegetarian_pizzas = Pizza.objects.filter(vegetarian=True)
>>> Restaurant.objects.prefetch_related(
...     Prefetch('pizzas', to_attr='menu'),
...     Prefetch('pizzas', queryset=vegetarian_pizzas, to_attr='vegetarian_menu'))
```

Lookups created with custom `to_attr` can still be traversed as usual by other lookups:

```
>>> vegetarian_pizzas = Pizza.objects.filter(vegetarian=True)
>>> Restaurant.objects.prefetch_related(
...     Prefetch('pizzas', queryset=vegetarian_pizzas, to_attr='vegetarian_menu'),
...     'vegetarian_menu__toppings')
```

Using `to_attr` is recommended when filtering down the prefetch result as it is less ambiguous than storing a filtered result in the related manager’s cache:

```
>>> queryset = Pizza.objects.filter(vegetarian=True)
>>>
>>> # Recommended:
>>> restaurants = Restaurant.objects.prefetch_related(
...     Prefetch('pizzas', queryset=queryset, to_attr='vegetarian_pizzas'))
>>> vegetarian_pizzas = restaurants[0].vegetarian_pizzas
>>>
>>> # Not recommended:
>>> restaurants = Restaurant.objects.prefetch_related(
...     Prefetch('pizzas', queryset=queryset))
>>> vegetarian_pizzas = restaurants[0].pizzas.all()
```

Custom prefetching also works with single related relations like forward `ForeignKey` or `OneToOneField`. Generally you'll want to use `select_related()` for these relations, but there are a number of cases where prefetching with a custom `QuerySet` is useful:

- You want to use a `QuerySet` that performs further prefetching on related models.
- You want to prefetch only a subset of the related objects.
- You want to use performance optimization techniques like *deferred fields*:

```
>>> queryset = Pizza.objects.only('name')
>>>
>>> restaurants = Restaurant.objects.prefetch_related(
...     Prefetch('best_pizza', queryset=queryset))
```

When using multiple databases, `Prefetch` will respect your choice of database. If the inner query does not specify a database, it will use the database selected by the outer query. All of the following are valid:

```
>>> # Both inner and outer queries will use the 'replica' database
>>> Restaurant.objects.prefetch_related("pizzas__toppings").using("replica")
>>> Restaurant.objects.prefetch_related(
...     Prefetch("pizzas__toppings"),
... ).using("replica")
>>>
>>> # Inner will use the 'replica' database; outer will use 'default' database
>>> Restaurant.objects.prefetch_related(
...     Prefetch("pizzas__toppings", queryset=Toppings.objects.using("replica")),
... )
>>>
>>> # Inner will use 'replica' database; outer will use 'cold-storage' database
>>> Restaurant.objects.prefetch_related(
...     Prefetch("pizzas__toppings", queryset=Toppings.objects.using("replica")),
... ).using("cold-storage")
```

Note: The ordering of lookups matters.

Take the following examples:

```
>>> prefetch_related('pizzas__toppings', 'pizzas')
```

This works even though it's unordered because 'pizzas__toppings' already contains all the needed information, therefore the second argument 'pizzas' is actually redundant.

```
>>> prefetch_related('pizzas__toppings', Prefetch('pizzas', queryset=Pizza.objects.all()))
```

This will raise a `ValueError` because of the attempt to redefine the queryset of a previously seen lookup. Note that an implicit queryset was created to traverse 'pizzas' as part of the 'pizzas__toppings' lookup.

```
>>> prefetch_related('pizza_list__toppings', Prefetch('pizzas', to_attr='pizza_list'))
```

This will trigger an `AttributeError` because 'pizza_list' doesn't exist yet when 'pizza_list__toppings' is being processed.

This consideration is not limited to the use of `Prefetch` objects. Some advanced techniques may require that the lookups be performed in a specific order to avoid creating extra queries; therefore it's recommended to always carefully order `prefetch_related` arguments.

`extra()`

`extra(select=None, where=None, params=None, tables=None, order_by=None, select_params=None)`

Sometimes, the Django query syntax by itself can't easily express a complex `WHERE` clause. For these edge cases, Django provides the `extra()` `QuerySet` modifier—a hook for injecting specific clauses into the SQL generated by a `QuerySet`.

Use this method as a last resort

This is an old API that we aim to deprecate at some point in the future. Use it only if you cannot express your query using other queryset methods. If you do need to use it, please [file a ticket](#) using the `QuerySet.extra` keyword with your use case (please check the list of existing tickets first) so that we can enhance the `QuerySet` API to allow removing `extra()`. We are no longer improving or fixing bugs for this method.

For example, this use of `extra()`:

```
>>> qs.extra(
...     select={"val": "select col from sometable where othercol = %s"},
```

(continues on next page)

(continued from previous page)

```
...     select_params=(someparam,),  
... )
```

is equivalent to:

```
>>> qs.annotate(val=RawSQL("select col from sometable where othercol = %s", (someparam,)))
```

The main benefit of using `RawSQL` is that you can set `output_field` if needed. The main downside is that if you refer to some table alias of the queryset in the raw SQL, then it is possible that Django might change that alias (for example, when the queryset is used as a subquery in yet another query).

Warning: You should be very careful whenever you use `extra()`. Every time you use it, you should escape any parameters that the user can control by using `params` in order to protect against SQL injection attacks.

You also must not quote placeholders in the SQL string. This example is vulnerable to SQL injection because of the quotes around `%s`:

```
SELECT col FROM sometable WHERE othercol = '%s' # unsafe!
```

You can read more about how Django's [SQL injection protection](#) works.

By definition, these extra lookups may not be portable to different database engines (because you're explicitly writing SQL code) and violate the DRY principle, so you should avoid them if possible.

Specify one or more of `params`, `select`, `where` or `tables`. None of the arguments is required, but you should use at least one of them.

- **select**

The `select` argument lets you put extra fields in the `SELECT` clause. It should be a dictionary mapping attribute names to SQL clauses to use to calculate that attribute.

Example:

```
Entry.objects.extra(select={"is_recent": "pub_date > '2006-01-01'"})
```

As a result, each `Entry` object will have an extra attribute, `is_recent`, a boolean representing whether the entry's `pub_date` is greater than Jan. 1, 2006.

Django inserts the given SQL snippet directly into the `SELECT` statement, so the resulting SQL of the above example would be something like:

```
SELECT blog_entry.*, (pub_date > '2006-01-01') AS is_recent  
FROM blog_entry;
```

The next example is more advanced; it does a subquery to give each resulting `Blog` object an `entry_count` attribute, an integer count of associated `Entry` objects:

```
Blog.objects.extra(
    select={
        "entry_count": "SELECT COUNT(*) FROM blog_entry WHERE blog_entry.blog_id = blog_blog.
↪id"
    },
)
```

In this particular case, we’re exploiting the fact that the query will already contain the `blog_blog` table in its `FROM` clause.

The resulting SQL of the above example would be:

```
SELECT blog_blog.*, (SELECT COUNT(*) FROM blog_entry WHERE blog_entry.blog_id = blog_blog.id)
↪AS entry_count
FROM blog_blog;
```

Note that the parentheses required by most database engines around subqueries are not required in Django’s `select` clauses. Also note that some database backends, such as some MySQL versions, don’t support subqueries.

In some rare cases, you might wish to pass parameters to the SQL fragments in `extra(select=...)`. For this purpose, use the `select_params` parameter.

This will work, for example:

```
Blog.objects.extra(
    select={"a": "%s", "b": "%s"},
    select_params=("one", "two"),
)
```

If you need to use a literal `%s` inside your select string, use the sequence `%%s`.

- **where / tables**

You can define explicit SQL `WHERE` clauses —perhaps to perform non-explicit joins —by using `where`. You can manually add tables to the SQL `FROM` clause by using `tables`.

`where` and `tables` both take a list of strings. All `where` parameters are “AND” ed to any other search criteria.

Example:

```
Entry.objects.extra(where=["foo='a' OR bar = 'a'", "baz = 'a'"])
```

...translates (roughly) into the following SQL:

```
SELECT * FROM blog_entry WHERE (foo='a' OR bar='a') AND (baz='a')
```

Be careful when using the `tables` parameter if you're specifying tables that are already used in the query. When you add extra tables via the `tables` parameter, Django assumes you want that table included an extra time, if it is already included. That creates a problem, since the table name will then be given an alias. If a table appears multiple times in an SQL statement, the second and subsequent occurrences must use aliases so the database can tell them apart. If you're referring to the extra table you added in the extra `where` parameter this is going to cause errors.

Normally you'll only be adding extra tables that don't already appear in the query. However, if the case outlined above does occur, there are a few solutions. First, see if you can get by without including the extra table and use the one already in the query. If that isn't possible, put your `extra()` call at the front of the queryset construction so that your table is the first use of that table. Finally, if all else fails, look at the query produced and rewrite your `where` addition to use the alias given to your extra table. The alias will be the same each time you construct the queryset in the same way, so you can rely upon the alias name to not change.

- `order_by`

If you need to order the resulting queryset using some of the new fields or tables you have included via `extra()` use the `order_by` parameter to `extra()` and pass in a sequence of strings. These strings should either be model fields (as in the normal `order_by()` method on querysets), of the form `table_name.column_name` or an alias for a column that you specified in the `select` parameter to `extra()`.

For example:

```
q = Entry.objects.extra(select={"is_recent": "pub_date > '2006-01-01'"})
q = q.extra(order_by=["-is_recent"])
```

This would sort all the items for which `is_recent` is true to the front of the result set (`True` sorts before `False` in a descending ordering).

This shows, by the way, that you can make multiple calls to `extra()` and it will behave as you expect (adding new constraints each time).

- `params`

The `where` parameter described above may use standard Python database string placeholders — `'%s'` to indicate parameters the database engine should automatically quote. The `params` argument is a list of any extra parameters to be substituted.

Example:

```
Entry.objects.extra(where=["headline=%s"], params=["Lennon"])
```

Always use `params` instead of embedding values directly into `where` because `params` will ensure values are quoted correctly according to your particular backend. For example, quotes will be escaped

correctly.

Bad:

```
Entry.objects.extra(where=["headline='Lennon'"])
```

Good:

```
Entry.objects.extra(where=["headline=%s"], params=["Lennon"])
```

Warning: If you are performing queries on MySQL, note that MySQL's silent type coercion may cause unexpected results when mixing types. If you query on a string type column, but with an integer value, MySQL will coerce the types of all values in the table to an integer before performing the comparison. For example, if your table contains the values 'abc', 'def' and you query for `WHERE mycolumn=0`, both rows will match. To prevent this, perform the correct typecasting before using the value in a query.

`defer()`

`defer(*fields)`

In some complex data-modeling situations, your models might contain a lot of fields, some of which could contain a lot of data (for example, text fields), or require expensive processing to convert them to Python objects. If you are using the results of a queryset in some situation where you don't know if you need those particular fields when you initially fetch the data, you can tell Django not to retrieve them from the database.

This is done by passing the names of the fields to not load to `defer()`:

```
Entry.objects.defer("headline", "body")
```

A queryset that has deferred fields will still return model instances. Each deferred field will be retrieved from the database if you access that field (one at a time, not all the deferred fields at once).

Note: Deferred fields will not lazy-load like this from asynchronous code. Instead, you will get a `SynchronousOnlyOperation` exception. If you are writing asynchronous code, you should not try to access any fields that you `defer()`.

You can make multiple calls to `defer()`. Each call adds new fields to the deferred set:

```
# Defers both the body and headline fields.
Entry.objects.defer("body").filter(rating=5).defer("headline")
```

The order in which fields are added to the deferred set does not matter. Calling `defer()` with a field name that has already been deferred is harmless (the field will still be deferred).

You can defer loading of fields in related models (if the related models are loading via `select_related()`) by using the standard double-underscore notation to separate related fields:

```
Blog.objects.select_related().defer("entry__headline", "entry__body")
```

If you want to clear the set of deferred fields, pass `None` as a parameter to `defer()`:

```
# Load all fields immediately.
my_queryset.defer(None)
```

Some fields in a model won't be deferred, even if you ask for them. You can never defer the loading of the primary key. If you are using `select_related()` to retrieve related models, you shouldn't defer the loading of the field that connects from the primary model to the related one, doing so will result in an error.

Note: The `defer()` method (and its cousin, `only()`, below) are only for advanced use-cases. They provide an optimization for when you have analyzed your queries closely and understand exactly what information you need and have measured that the difference between returning the fields you need and the full set of fields for the model will be significant.

Even if you think you are in the advanced use-case situation, only use `defer()` when you cannot, at queryset load time, determine if you will need the extra fields or not. If you are frequently loading and using a particular subset of your data, the best choice you can make is to normalize your models and put the non-loaded data into a separate model (and database table). If the columns must stay in the one table for some reason, create a model with `Meta.managed = False` (see the *managed attribute* documentation) containing just the fields you normally need to load and use that where you might otherwise call `defer()`. This makes your code more explicit to the reader, is slightly faster and consumes a little less memory in the Python process.

For example, both of these models use the same underlying database table:

```
class CommonlyUsedModel(models.Model):
    f1 = models.CharField(max_length=10)

    class Meta:
        managed = False
        db_table = "app_largetable"

class ManagedModel(models.Model):
    f1 = models.CharField(max_length=10)
    f2 = models.CharField(max_length=10)

    class Meta:
        db_table = "app_largetable"
```

(continues on next page)

(continued from previous page)

```
# Two equivalent QuerySets:
CommonlyUsedModel.objects.all()
ManagedModel.objects.defer("f2")
```

If many fields need to be duplicated in the unmanaged model, it may be best to create an abstract model with the shared fields and then have the unmanaged and managed models inherit from the abstract model.

Note: When calling `save()` for instances with deferred fields, only the loaded fields will be saved. See `save()` for more details.

`only()`

`only(*fields)`

The `only()` method is essentially the opposite of `defer()`. Only the fields passed into this method and that are not already specified as deferred are loaded immediately when the queryset is evaluated.

If you have a model where almost all the fields need to be deferred, using `only()` to specify the complementary set of fields can result in simpler code.

Suppose you have a model with fields `name`, `age` and `biography`. The following two queriesets are the same, in terms of deferred fields:

```
Person.objects.defer("age", "biography")
Person.objects.only("name")
```

Whenever you call `only()` it replaces the set of fields to load immediately. The method's name is mnemonic: only those fields are loaded immediately; the remainder are deferred. Thus, successive calls to `only()` result in only the final fields being considered:

```
# This will defer all fields except the headline.
Entry.objects.only("body", "rating").only("headline")
```

Since `defer()` acts incrementally (adding fields to the deferred list), you can combine calls to `only()` and `defer()` and things will behave logically:

```
# Final result is that everything except "headline" is deferred.
Entry.objects.only("headline", "body").defer("body")
```

(continues on next page)

(continued from previous page)

```
# Final result loads headline immediately.  
Entry.objects.defer("body").only("headline", "body")
```

All of the cautions in the note for the `defer()` documentation apply to `only()` as well. Use it cautiously and only after exhausting your other options.

Using `only()` and omitting a field requested using `select_related()` is an error as well.

As with `defer()`, you cannot access the non-loaded fields from asynchronous code and expect them to load. Instead, you will get a `SynchronousOnlyOperation` exception. Ensure that all fields you might access are in your `only()` call.

Note: When calling `save()` for instances with deferred fields, only the loaded fields will be saved. See `save()` for more details.

Note: When using `defer()` after `only()` the fields in `defer()` will override `only()` for fields that are listed in both.

`using()`

`using(alias)`

This method is for controlling which database the `QuerySet` will be evaluated against if you are using more than one database. The only argument this method takes is the alias of a database, as defined in [DATABASES](#).

For example:

```
# queries the database with the 'default' alias.  
>>> Entry.objects.all()  
  
# queries the database with the 'backup' alias  
>>> Entry.objects.using("backup")
```

`select_for_update()`

`select_for_update(nowait=False, skip_locked=False, of=(), no_key=False)`

Returns a queryset that will lock rows until the end of the transaction, generating a `SELECT ... FOR UPDATE` SQL statement on supported databases.

For example:

```
from django.db import transaction

entries = Entry.objects.select_for_update().filter(author=request.user)
with transaction.atomic():
    for entry in entries:
        ...
```

When the queryset is evaluated (`for entry in entries` in this case), all matched entries will be locked until the end of the transaction block, meaning that other transactions will be prevented from changing or acquiring locks on them.

Usually, if another transaction has already acquired a lock on one of the selected rows, the query will block until the lock is released. If this is not the behavior you want, call `select_for_update(nowait=True)`. This will make the call non-blocking. If a conflicting lock is already acquired by another transaction, `DatabaseError` will be raised when the queryset is evaluated. You can also ignore locked rows by using `select_for_update(skip_locked=True)` instead. The `nowait` and `skip_locked` are mutually exclusive and attempts to call `select_for_update()` with both options enabled will result in a `ValueError`.

By default, `select_for_update()` locks all rows that are selected by the query. For example, rows of related objects specified in `select_related()` are locked in addition to rows of the queryset's model. If this isn't desired, specify the related objects you want to lock in `select_for_update(of=())` using the same fields syntax as `select_related()`. Use the value `'self'` to refer to the queryset's model.

Lock parents models in `select_for_update(of=())`

If you want to lock parents models when using [multi-table inheritance](#), you must specify parent link fields (by default `<parent_model_name>_ptr`) in the `of` argument. For example:

```
Restaurant.objects.select_for_update(of=("self", "place_ptr"))
```

Using `select_for_update(of=())` with specified fields

If you want to lock models and specify selected fields, e.g. using `values()`, you must select at least one field from each model in the `of` argument. Models without selected fields will not be locked.

On PostgreSQL only, you can pass `no_key=True` in order to acquire a weaker lock, that still allows creating rows that merely reference locked rows (through a foreign key, for example) while the lock is in place. The PostgreSQL documentation has more details about [row-level lock modes](#).

You can't use `select_for_update()` on nullable relations:

```
>>> Person.objects.select_related("hometown").select_for_update()
Traceback (most recent call last):
...
django.db.utils.NotSupportedError: FOR UPDATE cannot be applied to the nullable side of an outer_
↳ join
```

To avoid that restriction, you can exclude null objects if you don't care about them:

```
>>> Person.objects.select_related("hometown").select_for_update().exclude(hometown=None)
<QuerySet [<Person: ...>, ...]>
```

The `postgresql`, `oracle`, and `mysql` database backends support `select_for_update()`. However, MariaDB only supports the `nowait` argument, MariaDB 10.6+ also supports the `skip_locked` argument, and MySQL 8.0.1+ supports the `nowait`, `skip_locked`, and `of` arguments. The `no_key` argument is only supported on PostgreSQL.

Passing `nowait=True`, `skip_locked=True`, `no_key=True`, or `of` to `select_for_update()` using database backends that do not support these options, such as MySQL, raises a *NotSupportedError*. This prevents code from unexpectedly blocking.

Evaluating a queryset with `select_for_update()` in autocommit mode on backends which support `SELECT ... FOR UPDATE` is a *TransactionManagementError* error because the rows are not locked in that case. If allowed, this would facilitate data corruption and could easily be caused by calling code that expects to be run in a transaction outside of one.

Using `select_for_update()` on backends which do not support `SELECT ... FOR UPDATE` (such as SQLite) will have no effect. `SELECT ... FOR UPDATE` will not be added to the query, and an error isn't raised if `select_for_update()` is used in autocommit mode.

Warning: Although `select_for_update()` normally fails in autocommit mode, since *TestCase* automatically wraps each test in a transaction, calling `select_for_update()` in a *TestCase* even outside an *atomic()* block will (perhaps unexpectedly) pass without raising a *TransactionManagementError*. To properly test `select_for_update()` you should use *TransactionTestCase*.

Certain expressions may not be supported

PostgreSQL doesn't support `select_for_update()` with *Window* expressions.

`raw()`

`raw(raw_query, params=(), translations=None, using=None)`

Takes a raw SQL query, executes it, and returns a `django.db.models.query.RawQuerySet` instance. This `RawQuerySet` instance can be iterated over just like a normal `QuerySet` to provide object instances.

See the [Performing raw SQL queries](#) for more information.

Warning: `raw()` always triggers a new query and doesn't account for previous filtering. As such, it should generally be called from the `Manager` or from a fresh `QuerySet` instance.

Operators that return new QuerySets

Combined querysets must use the same model.

AND (&)

Combines two `QuerySets` using the SQL AND operator in a manner similar to chaining filters.

The following are equivalent:

```
Model.objects.filter(x=1) & Model.objects.filter(y=2)
Model.objects.filter(x=1).filter(y=2)
```

SQL equivalent:

```
SELECT ... WHERE x=1 AND y=2
```

OR (|)

Combines two `QuerySets` using the SQL OR operator.

The following are equivalent:

```
Model.objects.filter(x=1) | Model.objects.filter(y=2)
from django.db.models import Q

Model.objects.filter(Q(x=1) | Q(y=2))
```

SQL equivalent:

```
SELECT ... WHERE x=1 OR y=2
```

| is not a commutative operation, as different (though equivalent) queries may be generated.

XOR (^)

Combines two `QuerySets` using the SQL XOR operator.

The following are equivalent:

```
Model.objects.filter(x=1) ^ Model.objects.filter(y=2)
from django.db.models import Q

Model.objects.filter(Q(x=1) ^ Q(y=2))
```

SQL equivalent:

```
SELECT ... WHERE x=1 XOR y=2
```

Note: XOR is natively supported on MariaDB and MySQL. On other databases, $x \wedge y \wedge \dots \wedge z$ is converted to an equivalent:

```
(x OR y OR ... OR z) AND
1=(
    (CASE WHEN x THEN 1 ELSE 0 END) +
    (CASE WHEN y THEN 1 ELSE 0 END) +
    ...
    (CASE WHEN z THEN 1 ELSE 0 END) +
)
```

Methods that do not return QuerySets

The following `QuerySet` methods evaluate the `QuerySet` and return something other than a `QuerySet`.

These methods do not use a cache (see [Caching and QuerySets](#)). Rather, they query the database each time they're called.

Because these methods evaluate the `QuerySet`, they are blocking calls, and so their main (synchronous) versions cannot be called from asynchronous code. For this reason, each has a corresponding asynchronous version with an `a` prefix - for example, rather than `get(...)` you can `await aget(...)`.

There is usually no difference in behavior apart from their asynchronous nature, but any differences are noted below next to each method.

The asynchronous versions of each method, prefixed with `a` was added.

`get()`

`get(*args, **kwargs)`

`aget(*args, **kwargs)`

Asynchronous version: `aget()`

Returns the object matching the given lookup parameters, which should be in the format described in [Field lookups](#). You should use lookups that are guaranteed unique, such as the primary key or fields in a unique constraint. For example:

```
Entry.objects.get(id=1)
Entry.objects.get(Q(blog=blog) & Q(entry_number=1))
```

If you expect a queryset to already return one row, you can use `get()` without any arguments to return the object for that row:

```
Entry.objects.filter(pk=1).get()
```

If `get()` doesn't find any object, it raises a `Model.DoesNotExist` exception:

```
Entry.objects.get(id=-999) # raises Entry.DoesNotExist
```

If `get()` finds more than one object, it raises a `Model.MultipleObjectsReturned` exception:

```
Entry.objects.get(name="A Duplicated Name") # raises Entry.MultipleObjectsReturned
```

Both these exception classes are attributes of the model class, and specific to that model. If you want to handle such exceptions from several `get()` calls for different models, you can use their generic base classes. For example, you can use `django.core.exceptions.ObjectDoesNotExist` to handle `DoesNotExist` exceptions from multiple models:

```
from django.core.exceptions import ObjectDoesNotExist

try:
    blog = Blog.objects.get(id=1)
    entry = Entry.objects.get(blog=blog, entry_number=1)
except ObjectDoesNotExist:
    print("Either the blog or entry doesn't exist.")
```

`aget()` method was added.

```
create()
```

```
create(**kwargs)
```

```
acreate(*args, **kwargs)
```

Asynchronous version: `acreate()`

A convenience method for creating an object and saving it all in one step. Thus:

```
p = Person.objects.create(first_name="Bruce", last_name="Springsteen")
```

and:

```
p = Person(first_name="Bruce", last_name="Springsteen")
p.save(force_insert=True)
```

are equivalent.

The `force_insert` parameter is documented elsewhere, but all it means is that a new object will always be created. Normally you won't need to worry about this. However, if your model contains a manual primary key value that you set and if that value already exists in the database, a call to `create()` will fail with an *IntegrityError* since primary keys must be unique. Be prepared to handle the exception if you are using manual primary keys.

`acreate()` method was added.

```
get_or_create()
```

```
get_or_create(defaults=None, **kwargs)
```

```
aget_or_create(defaults=None, **kwargs)
```

Asynchronous version: `aget_or_create()`

A convenience method for looking up an object with the given `kwargs` (may be empty if your model has defaults for all fields), creating one if necessary.

Returns a tuple of (`object`, `created`), where `object` is the retrieved or created object and `created` is a boolean specifying whether a new object was created.

This is meant to prevent duplicate objects from being created when requests are made in parallel, and as a shortcut to boilerplatish code. For example:

```
try:
    obj = Person.objects.get(first_name="John", last_name="Lennon")
except Person.DoesNotExist:
```

(continues on next page)

(continued from previous page)

```
obj = Person(first_name="John", last_name="Lennon", birthday=date(1940, 10, 9))
obj.save()
```

Here, with concurrent requests, multiple attempts to save a `Person` with the same parameters may be made. To avoid this race condition, the above example can be rewritten using `get_or_create()` like so:

```
obj, created = Person.objects.get_or_create(
    first_name="John",
    last_name="Lennon",
    defaults={"birthday": date(1940, 10, 9)},
)
```

Any keyword arguments passed to `get_or_create()` —except an optional one called `defaults`—will be used in a `get()` call. If an object is found, `get_or_create()` returns a tuple of that object and `False`.

Warning: This method is atomic assuming that the database enforces uniqueness of the keyword arguments (see [unique](#) or [unique_together](#)). If the fields used in the keyword arguments do not have a uniqueness constraint, concurrent calls to this method may result in multiple rows with the same parameters being inserted.

You can specify more complex conditions for the retrieved object by chaining `get_or_create()` with `filter()` and using [Q objects](#). For example, to retrieve Robert or Bob Marley if either exists, and create the latter otherwise:

```
from django.db.models import Q

obj, created = Person.objects.filter(
    Q(first_name="Bob") | Q(first_name="Robert"),
).get_or_create(last_name="Marley", defaults={"first_name": "Bob"})
```

If multiple objects are found, `get_or_create()` raises [MultipleObjectsReturned](#). If an object is not found, `get_or_create()` will instantiate and save a new object, returning a tuple of the new object and `True`. The new object will be created roughly according to this algorithm:

```
params = {k: v for k, v in kwargs.items() if "__" not in k}
params.update({k: v() if callable(v) else v for k, v in defaults.items()})
obj = self.model(**params)
obj.save()
```

In English, that means start with any non-`defaults` keyword argument that doesn't contain a double underscore (which would indicate a non-exact lookup). Then add the contents of `defaults`, overriding any keys if necessary, and use the result as the keyword arguments to the model class. If there are any callables

in `defaults`, evaluate them. As hinted at above, this is a simplification of the algorithm that is used, but it contains all the pertinent details. The internal implementation has some more error-checking than this and handles some extra edge-conditions; if you're interested, read the code.

If you have a field named `defaults` and want to use it as an exact lookup in `get_or_create()`, use `'defaults__exact'`, like so:

```
Foo.objects.get_or_create(defaults__exact="bar", defaults={"defaults": "baz"})
```

The `get_or_create()` method has similar error behavior to `create()` when you're using manually specified primary keys. If an object needs to be created and the key already exists in the database, an `IntegrityError` will be raised.

Finally, a word on using `get_or_create()` in Django views. Please make sure to use it only in POST requests unless you have a good reason not to. GET requests shouldn't have any effect on data. Instead, use POST whenever a request to a page has a side effect on your data. For more, see [Safe methods](#) in the HTTP spec.

Warning: You can use `get_or_create()` through *ManyToManyField* attributes and reverse relations. In that case you will restrict the queries inside the context of that relation. That could lead you to some integrity problems if you don't use it consistently.

Being the following models:

```
class Chapter(models.Model):
    title = models.CharField(max_length=255, unique=True)

class Book(models.Model):
    title = models.CharField(max_length=256)
    chapters = models.ManyToManyField(Chapter)
```

You can use `get_or_create()` through `Book`'s `chapters` field, but it only fetches inside the context of that book:

```
>>> book = Book.objects.create(title="Ulysses")
>>> book.chapters.get_or_create(title="Telemachus")
(<Chapter: Telemachus>, True)
>>> book.chapters.get_or_create(title="Telemachus")
(<Chapter: Telemachus>, False)
>>> Chapter.objects.create(title="Chapter 1")
<Chapter: Chapter 1>
>>> book.chapters.get_or_create(title="Chapter 1")
# Raises IntegrityError
```

This is happening because it's trying to get or create "Chapter 1" through the book "Ulysses", but it can't do any of them: the relation can't fetch that chapter because it isn't related to that book, but it can't create it either because `title` field should be unique.

`aget_or_create()` method was added.

`update_or_create()`

`update_or_create(defaults=None, **kwargs)`

`aupdate_or_create(defaults=None, **kwargs)`

Asynchronous version: `aupdate_or_create()`

A convenience method for updating an object with the given `kwargs`, creating a new one if necessary. The `defaults` is a dictionary of (field, value) pairs used to update the object. The values in `defaults` can be callables.

Returns a tuple of (object, created), where `object` is the created or updated object and `created` is a boolean specifying whether a new object was created.

The `update_or_create` method tries to fetch an object from database based on the given `kwargs`. If a match is found, it updates the fields passed in the `defaults` dictionary.

This is meant as a shortcut to boilerplatish code. For example:

```
defaults = {"first_name": "Bob"}
try:
    obj = Person.objects.get(first_name="John", last_name="Lennon")
    for key, value in defaults.items():
        setattr(obj, key, value)
    obj.save()
except Person.DoesNotExist:
    new_values = {"first_name": "John", "last_name": "Lennon"}
    new_values.update(defaults)
    obj = Person(**new_values)
    obj.save()
```

This pattern gets quite unwieldy as the number of fields in a model goes up. The above example can be rewritten using `update_or_create()` like so:

```
obj, created = Person.objects.update_or_create(
    first_name="John",
    last_name="Lennon",
    defaults={"first_name": "Bob"},
)
```

For a detailed description of how names passed in `kwargs` are resolved, see [get_or_create\(\)](#).

As described above in [get_or_create\(\)](#), this method is prone to a race-condition which can result in multiple rows being inserted simultaneously if uniqueness is not enforced at the database level.

Like `get_or_create()` and `create()`, if you're using manually specified primary keys and an object needs to be created but the key already exists in the database, an `IntegrityError` is raised.

`update_or_create()` method was added.

In older versions, `update_or_create()` didn't specify `update_fields` when calling `Model.save()`.

`bulk_create()`

`bulk_create(objs, batch_size=None, ignore_conflicts=False, update_conflicts=False, update_fields=None, unique_fields=None)`

`abulk_create(objs, batch_size=None, ignore_conflicts=False, update_conflicts=False, update_fields=None, unique_fields=None)`

Asynchronous version: `abulk_create()`

This method inserts the provided list of objects into the database in an efficient manner (generally only 1 query, no matter how many objects there are), and returns created objects as a list, in the same order as provided:

```
>>> objs = Entry.objects.bulk_create([
...     Entry(headline="This is a test"),
...     Entry(headline="This is only a test"),
... ])
... )
```

This has a number of caveats though:

- The model's `save()` method will not be called, and the `pre_save` and `post_save` signals will not be sent.
- It does not work with child models in a multi-table inheritance scenario.
- If the model's primary key is an `AutoField`, the primary key attribute can only be retrieved on certain databases (currently PostgreSQL, MariaDB 10.5+, and SQLite 3.35+). On other databases, it will not be set.
- It does not work with many-to-many relationships.
- It casts `objs` to a list, which fully evaluates `objs` if it's a generator. The cast allows inspecting all objects so that any objects with a manually set primary key can be inserted first. If you want to insert objects in batches without evaluating the entire generator at once, you can use this technique as long as the objects don't have any manually set primary keys:

```
from itertools import islice
```

(continues on next page)

(continued from previous page)

```

batch_size = 100
objs = (Entry(headline="Test %s" % i) for i in range(1000))
while True:
    batch = list(islice(objs, batch_size))
    if not batch:
        break
    Entry.objects.bulk_create(batch, batch_size)

```

The `batch_size` parameter controls how many objects are created in a single query. The default is to create all objects in one batch, except for SQLite where the default is such that at most 999 variables per query are used.

On databases that support it (all but Oracle), setting the `ignore_conflicts` parameter to `True` tells the database to ignore failure to insert any rows that fail constraints such as duplicate unique values.

On databases that support it (all except Oracle and SQLite < 3.24), setting the `update_conflicts` parameter to `True`, tells the database to update `update_fields` when a row insertion fails on conflicts. On PostgreSQL and SQLite, in addition to `update_fields`, a list of `unique_fields` that may be in conflict must be provided.

Enabling the `ignore_conflicts` or `update_conflicts` parameter disable setting the primary key on each model instance (if the database normally support it).

Warning: On MySQL and MariaDB, setting the `ignore_conflicts` parameter to `True` turns certain types of errors, other than duplicate key, into warnings. Even with Strict Mode. For example: invalid values or non-nullable violations. See the [MySQL documentation](#) and [MariaDB documentation](#) for more details.

The `update_conflicts`, `update_fields`, and `unique_fields` parameters were added to support updating fields when a row insertion fails on conflict.

`abulk_create()` method was added.

`bulk_update()`

`bulk_update(objs, fields, batch_size=None)`

`abulk_update(objs, fields, batch_size=None)`

Asynchronous version: `abulk_update()`

This method efficiently updates the given fields on the provided model instances, generally with one query, and returns the number of objects updated:

```
>>> objs = [
...     Entry.objects.create(headline="Entry 1"),
...     Entry.objects.create(headline="Entry 2"),
... ]
>>> objs[0].headline = "This is entry 1"
>>> objs[1].headline = "This is entry 2"
>>> Entry.objects.bulk_update(objs, ["headline"])
2
```

`QuerySet.update()` is used to save the changes, so this is more efficient than iterating through the list of models and calling `save()` on each of them, but it has a few caveats:

- You cannot update the model's primary key.
- Each model's `save()` method isn't called, and the `pre_save` and `post_save` signals aren't sent.
- If updating a large number of columns in a large number of rows, the SQL generated can be very large. Avoid this by specifying a suitable `batch_size`.
- Updating fields defined on multi-table inheritance ancestors will incur an extra query per ancestor.
- When an individual batch contains duplicates, only the first instance in that batch will result in an update.
- The number of objects updated returned by the function may be fewer than the number of objects passed in. This can be due to duplicate objects passed in which are updated in the same batch or race conditions such that objects are no longer present in the database.

The `batch_size` parameter controls how many objects are saved in a single query. The default is to update all objects in one batch, except for SQLite and Oracle which have restrictions on the number of variables used in a query.

`abulk_update()` method was added.

`count()`

`count()`

`acount()`

Asynchronous version: `acount()`

Returns an integer representing the number of objects in the database matching the `QuerySet`.

Example:

```
# Returns the total number of entries in the database.
Entry.objects.count()
```

(continues on next page)

(continued from previous page)

```
# Returns the number of entries whose headline contains 'Lennon'
Entry.objects.filter(headline__contains="Lennon").count()
```

A `count()` call performs a `SELECT COUNT(*)` behind the scenes, so you should always use `count()` rather than loading all of the record into Python objects and calling `len()` on the result (unless you need to load the objects into memory anyway, in which case `len()` will be faster).

Note that if you want the number of items in a `QuerySet` and are also retrieving model instances from it (for example, by iterating over it), it's probably more efficient to use `len(queryset)` which won't cause an extra database query like `count()` would.

If the `queryset` has already been fully retrieved, `count()` will use that length rather than perform an extra database query.

`acount()` method was added.

`in_bulk()`

`in_bulk(id_list=None, *, field_name='pk')`

`ain_bulk(id_list=None, *, field_name='pk')`

Asynchronous version: `ain_bulk()`

Takes a list of field values (`id_list`) and the `field_name` for those values, and returns a dictionary mapping each value to an instance of the object with the given field value. No *`django.core.exceptions.ObjectDoesNotExist`* exceptions will ever be raised by `in_bulk`; that is, any `id_list` value not matching any instance will simply be ignored. If `id_list` isn't provided, all objects in the `queryset` are returned. `field_name` must be a unique field or a distinct field (if there's only one field specified in *`distinct()`*). `field_name` defaults to the primary key.

Example:

```
>>> Blog.objects.in_bulk([1])
{1: <Blog: Beatles Blog>}
>>> Blog.objects.in_bulk([1, 2])
{1: <Blog: Beatles Blog>, 2: <Blog: Cheddar Talk>}
>>> Blog.objects.in_bulk([])
{}
>>> Blog.objects.in_bulk()
{1: <Blog: Beatles Blog>, 2: <Blog: Cheddar Talk>, 3: <Blog: Django Weblog>}
>>> Blog.objects.in_bulk(["beatles_blog"], field_name="slug")
{'beatles_blog': <Blog: Beatles Blog>}
>>> Blog.objects.distinct("name").in_bulk(field_name="name")
```

(continues on next page)

(continued from previous page)

```
{'Beatles Blog': <Blog: Beatles Blog>, 'Cheddar Talk': <Blog: Cheddar Talk>, 'Django Weblog':  
↪<Blog: Django Weblog>}
```

If you pass `in_bulk()` an empty list, you'll get an empty dictionary.

`in_bulk()` method was added.

`iterator()`

`iterator(chunk_size=None)`

`aiterator(chunk_size=None)`

Asynchronous version: `aiterator()`

Evaluates the `QuerySet` (by performing the query) and returns an iterator (see [PEP 234](#)) over the results, or an asynchronous iterator (see [PEP 492](#)) if you call its asynchronous version `aiterator`.

A `QuerySet` typically caches its results internally so that repeated evaluations do not result in additional queries. In contrast, `iterator()` will read results directly, without doing any caching at the `QuerySet` level (internally, the default iterator calls `iterator()` and caches the return value). For a `QuerySet` which returns a large number of objects that you only need to access once, this can result in better performance and a significant reduction in memory.

Note that using `iterator()` on a `QuerySet` which has already been evaluated will force it to evaluate again, repeating the query.

`iterator()` is compatible with previous calls to `prefetch_related()` as long as `chunk_size` is given. Larger values will necessitate fewer queries to accomplish the prefetching at the cost of greater memory usage.

Note: `aiterator()` is not compatible with previous calls to `prefetch_related()`.

On some databases (e.g. Oracle, [SQLite](#)), the maximum number of terms in an SQL `IN` clause might be limited. Hence values below this limit should be used. (In particular, when prefetching across two or more relations, a `chunk_size` should be small enough that the anticipated number of results for each prefetched relation still falls below the limit.)

So long as the `QuerySet` does not prefetch any related objects, providing no value for `chunk_size` will result in Django using an implicit default of 2000.

Depending on the database backend, query results will either be loaded all at once or streamed from the database using server-side cursors.

Support for prefetching related objects was added to `iterator()`.

`aiterator()` method was added.

Deprecated since version 4.1: Using `iterator()` on a queryset that prefetches related objects without providing the `chunk_size` is deprecated. In Django 5.0, an exception will be raised.

With server-side cursors

Oracle and PostgreSQL use server-side cursors to stream results from the database without loading the entire result set into memory.

The Oracle database driver always uses server-side cursors.

With server-side cursors, the `chunk_size` parameter specifies the number of results to cache at the database driver level. Fetching bigger chunks diminishes the number of round trips between the database driver and the database, at the expense of memory.

On PostgreSQL, server-side cursors will only be used when the `DISABLE_SERVER_SIDE_CURSORS` setting is `False`. Read [Transaction pooling and server-side cursors](#) if you're using a connection pooler configured in transaction pooling mode. When server-side cursors are disabled, the behavior is the same as databases that don't support server-side cursors.

Without server-side cursors

MySQL doesn't support streaming results, hence the Python database driver loads the entire result set into memory. The result set is then transformed into Python row objects by the database adapter using the `fetchmany()` method defined in [PEP 249](#).

SQLite can fetch results in batches using `fetchmany()`, but since SQLite doesn't provide isolation between queries within a connection, be careful when writing to the table being iterated over. See [Isolation when using `QuerySet.iterator\(\)`](#) for more information.

The `chunk_size` parameter controls the size of batches Django retrieves from the database driver. Larger batches decrease the overhead of communicating with the database driver at the expense of a slight increase in memory consumption.

So long as the `QuerySet` does not prefetch any related objects, providing no value for `chunk_size` will result in Django using an implicit default of 2000, a value derived from [a calculation on the `psycpg` mailing list](#):

Assuming rows of 10-20 columns with a mix of textual and numeric data, 2000 is going to fetch less than 100KB of data, which seems a good compromise between the number of rows transferred and the data discarded if the loop is exited early.

`latest()`

`latest(*fields)`

`alatest(*fields)`

Asynchronous version: `alatest()`

Returns the latest object in the table based on the given field(s).

This example returns the latest `Entry` in the table, according to the `pub_date` field:

```
Entry.objects.latest("pub_date")
```

You can also choose the latest based on several fields. For example, to select the `Entry` with the earliest `expire_date` when two entries have the same `pub_date`:

```
Entry.objects.latest("pub_date", "-expire_date")
```

The negative sign in `'-expire_date'` means to sort `expire_date` in descending order. Since `latest()` gets the last result, the `Entry` with the earliest `expire_date` is selected.

If your model's `Meta` specifies `get_latest_by`, you can omit any arguments to `earliest()` or `latest()`. The fields specified in `get_latest_by` will be used by default.

Like `get()`, `earliest()` and `latest()` raise `DoesNotExist` if there is no object with the given parameters.

Note that `earliest()` and `latest()` exist purely for convenience and readability.

`earliest()` and `latest()` may return instances with null dates.

Since ordering is delegated to the database, results on fields that allow null values may be ordered differently if you use different databases. For example, PostgreSQL and MySQL sort null values as if they are higher than non-null values, while SQLite does the opposite.

You may want to filter out null values:

```
Entry.objects.filter(pub_date__isnull=False).latest("pub_date")
```

`alatest()` method was added.

`earliest()`

`earliest(*fields)`

`aearliest(*fields)`

Asynchronous version: `aearliest()`

Works otherwise like `latest()` except the direction is changed.

`aearliest()` method was added.

`first()`

`first()`

`afirst()`

Asynchronous version: `afirst()`

Returns the first object matched by the queryset, or `None` if there is no matching object. If the `QuerySet` has no ordering defined, then the queryset is automatically ordered by the primary key. This can affect aggregation results as described in [Interaction with `order\_by\(\)`](#).

Example:

```
p = Article.objects.order_by("title", "pub_date").first()
```

Note that `first()` is a convenience method, the following code sample is equivalent to the above example:

```
try:
    p = Article.objects.order_by("title", "pub_date")[0]
except IndexError:
    p = None
```

`afirst()` method was added.

`last()`

`last()`

`alast()`

Asynchronous version: `alast()`

Works like `first()`, but returns the last object in the queryset.

`alast()` method was added.

`aggregate()`

`aggregate(*args, **kwargs)`

`aaggregate(*args, **kwargs)`

Asynchronous version: `aaggregate()`

Returns a dictionary of aggregate values (averages, sums, etc.) calculated over the `QuerySet`. Each argument to `aggregate()` specifies a value that will be included in the dictionary that is returned.

The aggregation functions that are provided by Django are described in [Aggregation Functions](#) below. Since aggregates are also [query expressions](#), you may combine aggregates with other aggregates or values to create complex aggregates.

Aggregates specified using keyword arguments will use the keyword as the name for the annotation. Anonymous arguments will have a name generated for them based upon the name of the aggregate function and the model field that is being aggregated. Complex aggregates cannot use anonymous arguments and must specify a keyword argument as an alias.

For example, when you are working with blog entries, you may want to know the number of authors that have contributed blog entries:

```
>>> from django.db.models import Count
>>> q = Blog.objects.aggregate(Count("entry"))
{'entry__count': 16}
```

By using a keyword argument to specify the aggregate function, you can control the name of the aggregation value that is returned:

```
>>> q = Blog.objects.aggregate(number_of_entries=Count("entry"))
{'number_of_entries': 16}
```

For an in-depth discussion of aggregation, see [the topic guide on Aggregation](#).

`aaggregate()` method was added.

`exists()`

`exists()`

`aexists()`

Asynchronous version: `aexists()`

Returns `True` if the [QuerySet](#) contains any results, and `False` if not. This tries to perform the query in the simplest and fastest way possible, but it does execute nearly the same query as a normal [QuerySet](#) query.

`exists()` is useful for searches relating to the existence of any objects in a *QuerySet*, particularly in the context of a large *QuerySet*.

To find whether a queryset contains any items:

```
if some_queryset.exists():
    print("There is at least one object in some_queryset")
```

Which will be faster than:

```
if some_queryset:
    print("There is at least one object in some_queryset")
```

... but not by a large degree (hence needing a large queryset for efficiency gains).

Additionally, if a `some_queryset` has not yet been evaluated, but you know that it will be at some point, then using `some_queryset.exists()` will do more overall work (one query for the existence check plus an extra one to later retrieve the results) than using `bool(some_queryset)`, which retrieves the results and then checks if any were returned.

`aexists()` method was added.

`contains()`

`contains(obj)`

`acontains(obj)`

Asynchronous version: `acontains()`

Returns `True` if the *QuerySet* contains `obj`, and `False` if not. This tries to perform the query in the simplest and fastest way possible.

`contains()` is useful for checking an object membership in a *QuerySet*, particularly in the context of a large *QuerySet*.

To check whether a queryset contains a specific item:

```
if some_queryset.contains(obj):
    print("Entry contained in queryset")
```

This will be faster than the following which requires evaluating and iterating through the entire queryset:

```
if obj in some_queryset:
    print("Entry contained in queryset")
```

Like `exists()`, if `some_queryset` has not yet been evaluated, but you know that it will be at some point, then using `some_queryset.contains(obj)` will make an additional database query, generally resulting in slower overall performance.

`acontains()` method was added.

`update()`

`update(**kwargs)`

`auupdate(**kwargs)`

Asynchronous version: `auupdate()`

Performs an SQL update query for the specified fields, and returns the number of rows matched (which may not be equal to the number of rows updated if some rows already have the new value).

For example, to turn comments off for all blog entries published in 2010, you could do this:

```
>>> Entry.objects.filter(pub_date__year=2010).update(comments_on=False)
```

(This assumes your `Entry` model has fields `pub_date` and `comments_on`.)

You can update multiple fields —there’s no limit on how many. For example, here we update the `comments_on` and `headline` fields:

```
>>> Entry.objects.filter(pub_date__year=2010).update(
...     comments_on=False, headline="This is old"
... )
```

The `update()` method is applied instantly, and the only restriction on the `QuerySet` that is updated is that it can only update columns in the model’s main table, not on related models. You can’t do this, for example:

```
>>> Entry.objects.update(blog__name="foo") # Won't work!
```

Filtering based on related fields is still possible, though:

```
>>> Entry.objects.filter(blog__id=1).update(comments_on=True)
```

You cannot call `update()` on a `QuerySet` that has had a slice taken or can otherwise no longer be filtered.

The `update()` method returns the number of affected rows:

```
>>> Entry.objects.filter(id=64).update(comments_on=True)
1

>>> Entry.objects.filter(slug="nonexistent-slug").update(comments_on=True)
```

(continues on next page)

(continued from previous page)

```
0

>>> Entry.objects.filter(pub_date__year=2010).update(comments_on=False)
132
```

If you're just updating a record and don't need to do anything with the model object, the most efficient approach is to call `update()`, rather than loading the model object into memory. For example, instead of doing this:

```
e = Entry.objects.get(id=10)
e.comments_on = False
e.save()
```

...do this:

```
Entry.objects.filter(id=10).update(comments_on=False)
```

Using `update()` also prevents a race condition wherein something might change in your database in the short period of time between loading the object and calling `save()`.

Finally, realize that `update()` does an update at the SQL level and, thus, does not call any `save()` methods on your models, nor does it emit the `pre_save` or `post_save` signals (which are a consequence of calling `Model.save()`). If you want to update a bunch of records for a model that has a custom `save()` method, loop over them and call `save()`, like this:

```
for e in Entry.objects.filter(pub_date__year=2010):
    e.comments_on = False
    e.save()
```

`update()` method was added.

Ordered queryset

Chaining `order_by()` with `update()` is supported only on MariaDB and MySQL, and is ignored for different databases. This is useful for updating a unique field in the order that is specified without conflicts. For example:

```
Entry.objects.order_by("-number").update(number=F("number") + 1)
```

Note: `order_by()` clause will be ignored if it contains annotations, inherited fields, or lookups spanning relations.

`delete()`

`delete()`

`adelete()`

Asynchronous version: `adelete()`

Performs an SQL delete query on all rows in the *QuerySet* and returns the number of objects deleted and a dictionary with the number of deletions per object type.

The `delete()` is applied instantly. You cannot call `delete()` on a *QuerySet* that has had a slice taken or can otherwise no longer be filtered.

For example, to delete all the entries in a particular blog:

```
>>> b = Blog.objects.get(pk=1)

# Delete all the entries belonging to this Blog.
>>> Entry.objects.filter(blog=b).delete()
(4, {'blog.Entry': 2, 'blog.Entry_authors': 2})
```

By default, Django's *ForeignKey* emulates the SQL constraint `ON DELETE CASCADE` —in other words, any objects with foreign keys pointing at the objects to be deleted will be deleted along with them. For example:

```
>>> blogs = Blog.objects.all()

# This will delete all Blogs and all of their Entry objects.
>>> blogs.delete()
(5, {'blog.Blog': 1, 'blog.Entry': 2, 'blog.Entry_authors': 2})
```

This cascade behavior is customizable via the *on_delete* argument to the *ForeignKey*.

The `delete()` method does a bulk delete and does not call any `delete()` methods on your models. It does, however, emit the *pre_delete* and *post_delete* signals for all deleted objects (including cascaded deletions).

Django needs to fetch objects into memory to send signals and handle cascades. However, if there are no cascades and no signals, then Django may take a fast-path and delete objects without fetching into memory. For large deletes this can result in significantly reduced memory usage. The amount of executed queries can be reduced, too.

ForeignKeys which are set to *on_delete* `DO_NOTHING` do not prevent taking the fast-path in deletion.

Note that the queries generated in object deletion is an implementation detail subject to change.

`adelete()` method was added.

`as_manager()`

`classmethod as_manager()`

Class method that returns an instance of *Manager* with a copy of the `QuerySet`'s methods. See [Creating a manager with QuerySet methods](#) for more details.

Note that unlike the other entries in this section, this does not have an asynchronous variant as it does not execute a query.

`explain()`

`explain(format=None, **options)`

`aexplain(format=None, **options)`

Asynchronous version: `aexplain()`

Returns a string of the `QuerySet`'s execution plan, which details how the database would execute the query, including any indexes or joins that would be used. Knowing these details may help you improve the performance of slow queries.

For example, when using PostgreSQL:

```
>>> print(Blog.objects.filter(title="My Blog").explain())
Seq Scan on blog (cost=0.00..35.50 rows=10 width=12)
  Filter: (title = 'My Blog'::bpchar)
```

The output differs significantly between databases.

`explain()` is supported by all built-in database backends except Oracle because an implementation there isn't straightforward.

The `format` parameter changes the output format from the databases' default, which is usually text-based. PostgreSQL supports 'TEXT', 'JSON', 'YAML', and 'XML' formats. MariaDB and MySQL support 'TEXT' (also called 'TRADITIONAL') and 'JSON' formats. MySQL 8.0.16+ also supports an improved 'TREE' format, which is similar to PostgreSQL's 'TEXT' output and is used by default, if supported.

Some databases accept flags that can return more information about the query. Pass these flags as keyword arguments. For example, when using PostgreSQL:

```
>>> print(Blog.objects.filter(title="My Blog").explain(verbose=True, analyze=True))
Seq Scan on public.blog (cost=0.00..35.50 rows=10 width=12) (actual time=0.004..0.004 rows=10
↳ loops=1)
  Output: id, title
  Filter: (blog.title = 'My Blog'::bpchar)
```

(continues on next page)

(continued from previous page)

```
Planning time: 0.064 ms
Execution time: 0.058 ms
```

On some databases, flags may cause the query to be executed which could have adverse effects on your database. For example, the `ANALYZE` flag supported by MariaDB, MySQL 8.0.18+, and PostgreSQL could result in changes to data if there are triggers or if a function is called, even for a `SELECT` query.

`aexplain()` method was added.

Field lookups

Field lookups are how you specify the meat of an SQL `WHERE` clause. They're specified as keyword arguments to the `QuerySet` methods `filter()`, `exclude()` and `get()`.

For an introduction, see [models and database queries documentation](#).

Django's built-in lookups are listed below. It is also possible to write [custom lookups](#) for model fields.

As a convenience when no lookup type is provided (like in `Entry.objects.get(id=14)`) the lookup type is assumed to be `exact`.

`exact`

Exact match. If the value provided for comparison is `None`, it will be interpreted as an SQL `NULL` (see [isnull](#) for more details).

Examples:

```
Entry.objects.get(id__exact=14)
Entry.objects.get(id__exact=None)
```

SQL equivalents:

```
SELECT ... WHERE id = 14;
SELECT ... WHERE id IS NULL;
```

MySQL comparisons

In MySQL, a database table's "collation" setting determines whether `exact` comparisons are case-sensitive. This is a database setting, not a Django setting. It's possible to configure your MySQL tables to use case-sensitive comparisons, but some trade-offs are involved. For more information about this, see the [collation section](#) in the [databases](#) documentation.

`iexact`

Case-insensitive exact match. If the value provided for comparison is `None`, it will be interpreted as an SQL `NULL` (see [isnull](#) for more details).

Example:

```
Blog.objects.get(name__iexact="beatles blog")
Blog.objects.get(name__iexact=None)
```

SQL equivalents:

```
SELECT ... WHERE name ILIKE 'beatles blog';
SELECT ... WHERE name IS NULL;
```

Note the first query will match `'Beatles Blog'`, `'beatles blog'`, `'BeAtLes BLoG'`, etc.

SQLite users

When using the SQLite backend and non-ASCII strings, bear in mind the [database note](#) about string comparisons. SQLite does not do case-insensitive matching for non-ASCII strings.

`contains`

Case-sensitive containment test.

Example:

```
Entry.objects.get(headline__contains="Lennon")
```

SQL equivalent:

```
SELECT ... WHERE headline LIKE '%Lennon%';
```

Note this will match the headline `'Lennon honored today'` but not `'lennon honored today'`.

SQLite users

SQLite doesn't support case-sensitive `LIKE` statements; `contains` acts like `icontains` for SQLite. See the [database note](#) for more information.

`icontains`

Case-insensitive containment test.

Example:

```
Entry.objects.get(headline__icontains="Lennon")
```

SQL equivalent:

```
SELECT ... WHERE headline ILIKE '%Lennon%';
```

SQLite users

When using the SQLite backend and non-ASCII strings, bear in mind the [database note](#) about string comparisons.

`in`

In a given iterable; often a list, tuple, or queryset. It's not a common use case, but strings (being iterables) are accepted.

Examples:

```
Entry.objects.filter(id__in=[1, 3, 4])
Entry.objects.filter(headline__in="abc")
```

SQL equivalents:

```
SELECT ... WHERE id IN (1, 3, 4);
SELECT ... WHERE headline IN ('a', 'b', 'c');
```

You can also use a queryset to dynamically evaluate the list of values instead of providing a list of literal values:

```
inner_qs = Blog.objects.filter(name__contains="Cheddar")
entries = Entry.objects.filter(blog__in=inner_qs)
```

This queryset will be evaluated as subselect statement:

```
SELECT ... WHERE blog.id IN (SELECT id FROM ... WHERE NAME LIKE '%Cheddar%')
```

If you pass in a `QuerySet` resulting from `values()` or `values_list()` as the value to an `__in` lookup, you need to ensure you are only extracting one field in the result. For example, this will work (filtering on the

blog names):

```
inner_qs = Blog.objects.filter(name__contains="Ch").values("name")
entries = Entry.objects.filter(blog__name__in=inner_qs)
```

This example will raise an exception, since the inner query is trying to extract two field values, where only one is expected:

```
# Bad code! Will raise a TypeError.
inner_qs = Blog.objects.filter(name__contains="Ch").values("name", "id")
entries = Entry.objects.filter(blog__name__in=inner_qs)
```

Performance considerations

Be cautious about using nested queries and understand your database server's performance characteristics (if in doubt, benchmark!). Some database backends, most notably MySQL, don't optimize nested queries very well. It is more efficient, in those cases, to extract a list of values and then pass that into the second query. That is, execute two queries instead of one:

```
values = Blog.objects.filter(name__contains="Cheddar").values_list("pk", flat=True)
entries = Entry.objects.filter(blog__in=list(values))
```

Note the `list()` call around the `Blog QuerySet` to force execution of the first query. Without it, a nested query would be executed, because [QuerySets are lazy](#).

`gt`

Greater than.

Example:

```
Entry.objects.filter(id__gt=4)
```

SQL equivalent:

```
SELECT ... WHERE id > 4;
```

`gte`

Greater than or equal to.

`lt`

Less than.

`lte`

Less than or equal to.

`startswith`

Case-sensitive starts-with.

Example:

```
Entry.objects.filter(headline__startswith="Lennon")
```

SQL equivalent:

```
SELECT ... WHERE headline LIKE 'Lennon%';
```

SQLite doesn't support case-sensitive LIKE statements; `startswith` acts like `istartswith` for SQLite.

`istartswith`

Case-insensitive starts-with.

Example:

```
Entry.objects.filter(headline__istartswith="Lennon")
```

SQL equivalent:

```
SELECT ... WHERE headline ILIKE 'Lennon%';
```

SQLite users

When using the SQLite backend and non-ASCII strings, bear in mind the [database note](#) about string comparisons.

`endswith`

Case-sensitive ends-with.

Example:

```
Entry.objects.filter(headline__endswith="Lennon")
```

SQL equivalent:

```
SELECT ... WHERE headline LIKE '%Lennon';
```

SQLite users

SQLite doesn't support case-sensitive LIKE statements; `endswith` acts like `iendswith` for SQLite. Refer to the [database note](#) documentation for more.

`iendswith`

Case-insensitive ends-with.

Example:

```
Entry.objects.filter(headline__iendswith="Lennon")
```

SQL equivalent:

```
SELECT ... WHERE headline ILIKE '%Lennon'
```

SQLite users

When using the SQLite backend and non-ASCII strings, bear in mind the [database note](#) about string comparisons.

range

Range test (inclusive).

Example:

```
import datetime

start_date = datetime.date(2005, 1, 1)
end_date = datetime.date(2005, 3, 31)
Entry.objects.filter(pub_date__range=(start_date, end_date))
```

SQL equivalent:

```
SELECT ... WHERE pub_date BETWEEN '2005-01-01' and '2005-03-31';
```

You can use `range` anywhere you can use `BETWEEN` in SQL—for dates, numbers and even characters.

Warning: Filtering a `DateTimeField` with dates won't include items on the last day, because the bounds are interpreted as “0am on the given date”. If `pub_date` was a `DateTimeField`, the above expression would be turned into this SQL:

```
SELECT ... WHERE pub_date BETWEEN '2005-01-01 00:00:00' and '2005-03-31 00:00:00';
```

Generally speaking, you can't mix dates and datetimes.

date

For datetime fields, casts the value as date. Allows chaining additional field lookups. Takes a date value.

Example:

```
Entry.objects.filter(pub_date__date=datetime.date(2005, 1, 1))
Entry.objects.filter(pub_date__date__gt=datetime.date(2005, 1, 1))
```

(No equivalent SQL code fragment is included for this lookup because implementation of the relevant query varies among different database engines.)

When `USE_TZ` is `True`, fields are converted to the current time zone before filtering. This requires [time zone definitions in the database](#).

year

For date and datetime fields, an exact year match. Allows chaining additional field lookups. Takes an integer year.

Example:

```
Entry.objects.filter(pub_date__year=2005)
Entry.objects.filter(pub_date__year__gte=2005)
```

SQL equivalent:

```
SELECT ... WHERE pub_date BETWEEN '2005-01-01' AND '2005-12-31';
SELECT ... WHERE pub_date >= '2005-01-01';
```

(The exact SQL syntax varies for each database engine.)

When `USE_TZ` is `True`, datetime fields are converted to the current time zone before filtering. This requires [time zone definitions in the database](#).

iso_year

For date and datetime fields, an exact ISO 8601 week-numbering year match. Allows chaining additional field lookups. Takes an integer year.

Example:

```
Entry.objects.filter(pub_date__iso_year=2005)
Entry.objects.filter(pub_date__iso_year__gte=2005)
```

(The exact SQL syntax varies for each database engine.)

When `USE_TZ` is `True`, datetime fields are converted to the current time zone before filtering. This requires [time zone definitions in the database](#).

month

For date and datetime fields, an exact month match. Allows chaining additional field lookups. Takes an integer 1 (January) through 12 (December).

Example:

```
Entry.objects.filter(pub_date__month=12)
Entry.objects.filter(pub_date__month__gte=6)
```

SQL equivalent:

```
SELECT ... WHERE EXTRACT('month' FROM pub_date) = '12';
SELECT ... WHERE EXTRACT('month' FROM pub_date) >= '6';
```

(The exact SQL syntax varies for each database engine.)

When `USE_TZ` is `True`, datetime fields are converted to the current time zone before filtering. This requires [time zone definitions in the database](#).

day

For date and datetime fields, an exact day match. Allows chaining additional field lookups. Takes an integer day.

Example:

```
Entry.objects.filter(pub_date__day=3)
Entry.objects.filter(pub_date__day__gte=3)
```

SQL equivalent:

```
SELECT ... WHERE EXTRACT('day' FROM pub_date) = '3';
SELECT ... WHERE EXTRACT('day' FROM pub_date) >= '3';
```

(The exact SQL syntax varies for each database engine.)

Note this will match any record with a `pub_date` on the third day of the month, such as January 3, July 3, etc.

When `USE_TZ` is `True`, datetime fields are converted to the current time zone before filtering. This requires [time zone definitions in the database](#).

week

For date and datetime fields, return the week number (1-52 or 53) according to [ISO-8601](#), i.e., weeks start on a Monday and the first week contains the year's first Thursday.

Example:

```
Entry.objects.filter(pub_date__week=52)
Entry.objects.filter(pub_date__week__gte=32, pub_date__week__lte=38)
```

(No equivalent SQL code fragment is included for this lookup because implementation of the relevant query varies among different database engines.)

When `USE_TZ` is `True`, datetime fields are converted to the current time zone before filtering. This requires [time zone definitions in the database](#).

`week_day`

For date and datetime fields, a ‘day of the week’ match. Allows chaining additional field lookups.

Takes an integer value representing the day of week from 1 (Sunday) to 7 (Saturday).

Example:

```
Entry.objects.filter(pub_date__week_day=2)
Entry.objects.filter(pub_date__week_day__gte=2)
```

(No equivalent SQL code fragment is included for this lookup because implementation of the relevant query varies among different database engines.)

Note this will match any record with a `pub_date` that falls on a Monday (day 2 of the week), regardless of the month or year in which it occurs. Week days are indexed with day 1 being Sunday and day 7 being Saturday.

When `USE_TZ` is `True`, datetime fields are converted to the current time zone before filtering. This requires [time zone definitions in the database](#).

`iso_week_day`

For date and datetime fields, an exact ISO 8601 day of the week match. Allows chaining additional field lookups.

Takes an integer value representing the day of the week from 1 (Monday) to 7 (Sunday).

Example:

```
Entry.objects.filter(pub_date__iso_week_day=1)
Entry.objects.filter(pub_date__iso_week_day__gte=1)
```

(No equivalent SQL code fragment is included for this lookup because implementation of the relevant query varies among different database engines.)

Note this will match any record with a `pub_date` that falls on a Monday (day 1 of the week), regardless of the month or year in which it occurs. Week days are indexed with day 1 being Monday and day 7 being Sunday.

When `USE_TZ` is `True`, datetime fields are converted to the current time zone before filtering. This requires [time zone definitions in the database](#).

quarter

For date and datetime fields, a ‘quarter of the year’ match. Allows chaining additional field lookups. Takes an integer value between 1 and 4 representing the quarter of the year.

Example to retrieve entries in the second quarter (April 1 to June 30):

```
Entry.objects.filter(pub_date__quarter=2)
```

(No equivalent SQL code fragment is included for this lookup because implementation of the relevant query varies among different database engines.)

When `USE_TZ` is `True`, datetime fields are converted to the current time zone before filtering. This requires [time zone definitions in the database](#).

time

For datetime fields, casts the value as time. Allows chaining additional field lookups. Takes a `datetime.time` value.

Example:

```
Entry.objects.filter(pub_date__time=datetime.time(14, 30))
Entry.objects.filter(pub_date__time__range=(datetime.time(8), datetime.time(17)))
```

(No equivalent SQL code fragment is included for this lookup because implementation of the relevant query varies among different database engines.)

When `USE_TZ` is `True`, fields are converted to the current time zone before filtering. This requires [time zone definitions in the database](#).

hour

For datetime and time fields, an exact hour match. Allows chaining additional field lookups. Takes an integer between 0 and 23.

Example:

```
Event.objects.filter(timestamp__hour=23)
Event.objects.filter(time__hour=5)
Event.objects.filter(timestamp__hour__gte=12)
```

SQL equivalent:

```
SELECT ... WHERE EXTRACT('hour' FROM timestamp) = '23';
SELECT ... WHERE EXTRACT('hour' FROM time) = '5';
SELECT ... WHERE EXTRACT('hour' FROM timestamp) >= '12';
```

(The exact SQL syntax varies for each database engine.)

When `USE_TZ` is True, datetime fields are converted to the current time zone before filtering. This requires [time zone definitions in the database](#).

minute

For datetime and time fields, an exact minute match. Allows chaining additional field lookups. Takes an integer between 0 and 59.

Example:

```
Event.objects.filter(timestamp__minute=29)
Event.objects.filter(time__minute=46)
Event.objects.filter(timestamp__minute__gte=29)
```

SQL equivalent:

```
SELECT ... WHERE EXTRACT('minute' FROM timestamp) = '29';
SELECT ... WHERE EXTRACT('minute' FROM time) = '46';
SELECT ... WHERE EXTRACT('minute' FROM timestamp) >= '29';
```

(The exact SQL syntax varies for each database engine.)

When `USE_TZ` is True, datetime fields are converted to the current time zone before filtering. This requires [time zone definitions in the database](#).

second

For datetime and time fields, an exact second match. Allows chaining additional field lookups. Takes an integer between 0 and 59.

Example:

```
Event.objects.filter(timestamp__second=31)
Event.objects.filter(time__second=2)
Event.objects.filter(timestamp__second__gte=31)
```

SQL equivalent:

```
SELECT ... WHERE EXTRACT('second' FROM timestamp) = '31';
SELECT ... WHERE EXTRACT('second' FROM time) = '2';
SELECT ... WHERE EXTRACT('second' FROM timestamp) >= '31';
```

(The exact SQL syntax varies for each database engine.)

When `USE_TZ` is `True`, datetime fields are converted to the current time zone before filtering. This requires [time zone definitions in the database](#).

`isnull`

Takes either `True` or `False`, which correspond to SQL queries of `IS NULL` and `IS NOT NULL`, respectively.

Example:

```
Entry.objects.filter(pub_date__isnull=True)
```

SQL equivalent:

```
SELECT ... WHERE pub_date IS NULL;
```

`regex`

Case-sensitive regular expression match.

The regular expression syntax is that of the database backend in use. In the case of SQLite, which has no built in regular expression support, this feature is provided by a (Python) user-defined REGEXP function, and the regular expression syntax is therefore that of Python's `re` module.

Example:

```
Entry.objects.get(title__regex=r"^(An?|The) +")
```

SQL equivalents:

```
SELECT ... WHERE title REGEXP BINARY '^(An?|The) +'; -- MySQL

SELECT ... WHERE REGEXP_LIKE(title, '^(An?|The) +', 'c'); -- Oracle

SELECT ... WHERE title ~ '^(An?|The) +'; -- PostgreSQL

SELECT ... WHERE title REGEXP '^(An?|The) +'; -- SQLite
```

Using raw strings (e.g., `r'foo'` instead of `'foo'`) for passing in the regular expression syntax is recommended.

`iregex`

Case-insensitive regular expression match.

Example:

```
Entry.objects.get(title__iregex=r"^(an?|the) +")
```

SQL equivalents:

```
SELECT ... WHERE title REGEXP '^(an?|the) +'; -- MySQL

SELECT ... WHERE REGEXP_LIKE(title, '^(an?|the) +', 'i'); -- Oracle

SELECT ... WHERE title ~* '^(an?|the) +'; -- PostgreSQL

SELECT ... WHERE title REGEXP '(?i)^(an?|the) +'; -- SQLite
```

Aggregation functions

Django provides the following aggregation functions in the `django.db.models` module. For details on how to use these aggregate functions, see [the topic guide on aggregation](#). See the *Aggregate* documentation to learn how to create your aggregates.

Warning: SQLite can't handle aggregation on date/time fields out of the box. This is because there are no native date/time fields in SQLite and Django currently emulates these features using a text field. Attempts to use aggregation on date/time fields in SQLite will raise `NotSupportedError`.

Empty queryset

Aggregation functions return `None` when used with an empty `QuerySet`. For example, the `Sum` aggregation function returns `None` instead of 0 if the `QuerySet` contains no entries. To return another value instead, pass a value to the `default` argument. An exception is `Count`, which does return 0 if the `QuerySet` is empty. `Count` does not support the `default` argument.

All aggregates have the following parameters in common:

expressions

Strings that reference fields on the model, transforms of the field, or [query expressions](#).

output_field

An optional argument that represents the [model field](#) of the return value

Note: When combining multiple field types, Django can only determine the `output_field` if all fields are of the same type. Otherwise, you must provide the `output_field` yourself.

filter

An optional *Q object* that's used to filter the rows that are aggregated.

See [Conditional aggregation](#) and [Filtering on annotations](#) for example usage.

default

An optional argument that allows specifying a value to use as a default value when the queryset (or grouping) contains no entries.

****extra**

Keyword arguments that can provide extra context for the SQL generated by the aggregate.

Avg

class `Avg`(expression, output_field=None, distinct=False, filter=None, default=None, **extra)

Returns the mean value of the given expression, which must be numeric unless you specify a different `output_field`.

- Default alias: `<field>__avg`
- Return type: `float` if input is `int`, otherwise same as input field, or `output_field` if supplied

distinct

Optional. If `distinct=True`, `Avg` returns the mean value of unique values. This is the SQL equivalent of `AVG(DISTINCT <field>)`. The default value is `False`.

Count

class `Count`(expression, distinct=False, filter=None, **extra)

Returns the number of objects that are related through the provided expression. `Count('*')` is equivalent to the SQL `COUNT(*)` expression.

- Default alias: `<field>__count`
- Return type: `int`

distinct

Optional. If `distinct=True`, the count will only include unique instances. This is the SQL equivalent of `COUNT(DISTINCT <field>)`. The default value is `False`.

Note: The `default` argument is not supported.

Max

class `Max`(expression, output_field=None, filter=None, default=None, **extra)

Returns the maximum value of the given expression.

- Default alias: `<field>__max`
- Return type: same as input field, or `output_field` if supplied

Min

class `Min`(expression, output_field=None, filter=None, default=None, **extra)

Returns the minimum value of the given expression.

- Default alias: `<field>__min`
- Return type: same as input field, or `output_field` if supplied

StdDev

class `StdDev`(expression, output_field=None, sample=False, filter=None, default=None, **extra)

Returns the standard deviation of the data in the provided expression.

- Default alias: `<field>__stddev`
- Return type: `float` if input is `int`, otherwise same as input field, or `output_field` if supplied

sample

Optional. By default, `StdDev` returns the population standard deviation. However, if `sample=True`, the return value will be the sample standard deviation.

Sum

```
class Sum(expression, output_field=None, distinct=False, filter=None, default=None, **extra)
```

Computes the sum of all values of the given expression.

- Default alias: `<field>__sum`
- Return type: same as input field, or `output_field` if supplied

distinct

Optional. If `distinct=True`, `Sum` returns the sum of unique values. This is the SQL equivalent of `SUM(DISTINCT <field>)`. The default value is `False`.

Variance

```
class Variance(expression, output_field=None, sample=False, filter=None, default=None, **extra)
```

Returns the variance of the data in the provided expression.

- Default alias: `<field>__variance`
- Return type: `float` if input is `int`, otherwise same as input field, or `output_field` if supplied

sample

Optional. By default, `Variance` returns the population variance. However, if `sample=True`, the return value will be the sample variance.

Query-related tools

This section provides reference material for query-related tools not documented elsewhere.

Q() objects

```
class Q
```

A `Q()` object represents an SQL condition that can be used in database-related operations. It's similar to how an `F()` object represents the value of a model field or annotation. They make it possible to define and reuse conditions, and combine them using operators such as `|` (OR), `&` (AND), and `^` (XOR). See [Complex lookups with Q objects](#).

Support for the `^` (XOR) operator was added.

Prefetch() objects

```
class Prefetch(lookup, queryset=None, to_attr=None)
```

The `Prefetch()` object can be used to control the operation of `prefetch_related()`.

The `lookup` argument describes the relations to follow and works the same as the string based lookups passed to `prefetch_related()`. For example:

```
>>> from django.db.models import Prefetch
>>> Question.objects.prefetch_related(Prefetch('choice_set')).get().choice_set.all()
<QuerySet [<Choice: Not much>, <Choice: The sky>, <Choice: Just hacking again>]>
# This will only execute two queries regardless of the number of Question
# and Choice objects.
>>> Question.objects.prefetch_related(Prefetch('choice_set'))
<QuerySet [<Question: What's up?>]>
```

The `queryset` argument supplies a base `QuerySet` for the given lookup. This is useful to further filter down the prefetch operation, or to call `select_related()` from the prefetched relation, hence reducing the number of queries even further:

```
>>> voted_choices = Choice.objects.filter(votes__gt=0)
>>> voted_choices
<QuerySet [<Choice: The sky>]>
>>> prefetch = Prefetch('choice_set', queryset=voted_choices)
>>> Question.objects.prefetch_related(prefetch).get().choice_set.all()
<QuerySet [<Choice: The sky>]>
```

The `to_attr` argument sets the result of the prefetch operation to a custom attribute:

```
>>> prefetch = Prefetch('choice_set', queryset=voted_choices, to_attr='voted_choices')
>>> Question.objects.prefetch_related(prefetch).get().voted_choices
[<Choice: The sky>]
>>> Question.objects.prefetch_related(prefetch).get().choice_set.all()
<QuerySet [<Choice: Not much>, <Choice: The sky>, <Choice: Just hacking again>]>
```

Note: When using `to_attr` the prefetched result is stored in a list. This can provide a significant speed improvement over traditional `prefetch_related` calls which store the cached result within a `QuerySet` instance.

```
prefetch_related_objects()
```

```
prefetch_related_objects(model_instances, *related_lookups)
```

Prefetches the given lookups on an iterable of model instances. This is useful in code that receives a list of model instances as opposed to a `QuerySet`; for example, when fetching models from a cache or instantiating them manually.

Pass an iterable of model instances (must all be of the same class) and the lookups or *Prefetch* objects you want to prefetch for. For example:

```
>>> from django.db.models import prefetch_related_objects
>>> restaurants = fetch_top_restaurants_from_cache() # A list of Restaurants
>>> prefetch_related_objects(restaurants, "pizzas__toppings")
```

When using multiple databases with `prefetch_related_objects`, the prefetch query will use the database associated with the model instance. This can be overridden by using a custom queryset in a related lookup.

`FilteredRelation()` **objects**

```
class FilteredRelation(relation_name, *, condition=Q())
```

relation_name

The name of the field on which you'd like to filter the relation.

condition

A *Q* object to control the filtering.

`FilteredRelation` is used with *annotate()* to create an ON clause when a JOIN is performed. It doesn't act on the default relationship but on the annotation name (`pizzas_vegetarian` in example below).

For example, to find restaurants that have vegetarian pizzas with 'mozzarella' in the name:

```
>>> from django.db.models import FilteredRelation, Q
>>> Restaurant.objects.annotate(
...     pizzas_vegetarian=FilteredRelation(
...         "pizzas",
...         condition=Q(pizzas__vegetarian=True),
...     ),
... ).filter(pizzas_vegetarian__name__icontains="mozzarella")
```

If there are a large number of pizzas, this queryset performs better than:

```
>>> Restaurant.objects.filter(
...     pizzas__vegetarian=True,
```

(continues on next page)

(continued from previous page)

```
...     pizzas__name__icontains="mozzarella",
... )
```

because the filtering in the `WHERE` clause of the first queryset will only operate on vegetarian pizzas.

`FilteredRelation` doesn't support:

- `QuerySet.only()` and `prefetch_related()`.
- A `GenericForeignKey` inherited from a parent model.

6.16.11 Lookup API reference

This document has the API references of lookups, the Django API for building the `WHERE` clause of a database query. To learn how to use lookups, see [Making queries](#); to learn how to create new lookups, see [How to write custom lookups](#).

The lookup API has two components: a `RegisterLookupMixin` class that registers lookups, and the `Query Expression API`, a set of methods that a class has to implement to be registrable as a lookup.

Django has two base classes that follow the query expression API and from where all Django builtin lookups are derived:

- `Lookup`: to lookup a field (e.g. the exact of `field_name__exact`)
- `Transform`: to transform a field

A lookup expression consists of three parts:

- Fields part (e.g. `Book.objects.filter(author__best_friends__first_name...)`);
- Transforms part (may be omitted) (e.g. `__lower__first3chars__reversed`);
- A lookup (e.g. `__icontains`) that, if omitted, defaults to `__exact`.

Registration API

Django uses `RegisterLookupMixin` to give a class the interface to register lookups on itself or its instances. The two prominent examples are `Field`, the base class of all model fields, and `Transform`, the base class of all Django transforms.

```
class lookups.RegisterLookupMixin
```

A mixin that implements the lookup API on a class.

```
classmethod register_lookup(lookup, lookup_name=None)
```

Registers a new lookup in the class or class instance. For example:

```
DateField.register_lookup(YearExact)
User._meta.get_field("date_joined").register_lookup(MonthExact)
```

will register `YearExact` lookup on `DateField` and `MonthExact` lookup on the `User.date_joined` (you can use [Field Access API](#) to retrieve a single field instance). It overrides a lookup that already exists with the same name. Lookups registered on field instances take precedence over the lookups registered on classes. `lookup_name` will be used for this lookup if provided, otherwise `lookup.lookup_name` will be used.

get_lookup(lookup_name)

Returns the [Lookup](#) named `lookup_name` registered in the class or class instance depending on what calls it. The default implementation looks recursively on all parent classes and checks if any has a registered lookup named `lookup_name`, returning the first match. Instance lookups would override any class lookups with the same `lookup_name`.

get_lookups()

Returns a dictionary of each lookup name registered in the class or class instance mapped to the [Lookup](#) class.

get_transform(transform_name)

Returns a [Transform](#) named `transform_name` registered in the class or class instance. The default implementation looks recursively on all parent classes to check if any has the registered transform named `transform_name`, returning the first match.

For a class to be a lookup, it must follow the [Query Expression API](#). [Lookup](#) and [Transform](#) naturally follow this API.

Support for registering lookups on [Field](#) instances was added.

The Query Expression API

The query expression API is a common set of methods that classes define to be usable in query expressions to translate themselves into SQL expressions. Direct field references, aggregates, and [Transform](#) are examples that follow this API. A class is said to follow the query expression API when it implements the following methods:

as_sql(compiler, connection)

Generates the SQL fragment for the expression. Returns a tuple (`sql`, `params`), where `sql` is the SQL string, and `params` is the list or tuple of query parameters. The `compiler` is an `SQLCompiler` object, which has a `compile()` method that can be used to compile other expressions. The `connection` is the connection used to execute the query.

Calling `expression.as_sql()` is usually incorrect - instead `compiler.compile(expression)` should be used. The `compiler.compile()` method will take care of calling vendor-specific methods of the expression.

Custom keyword arguments may be defined on this method if it's likely that `as_vendorname()` methods or subclasses will need to supply data to override the generation of the SQL string. See [Func.as_sql\(\)](#) for example usage.

as_vendorname(compiler, connection)

Works like `as_sql()` method. When an expression is compiled by `compiler.compile()`, Django will first try to call `as_vendorname()`, where `vendorname` is the vendor name of the backend used for executing the query. The `vendorname` is one of `postgresql`, `oracle`, `sqlite`, or `mysql` for Django's built-in backends.

get_lookup(lookup_name)

Must return the lookup named `lookup_name`. For instance, by returning `self.output_field.get_lookup(lookup_name)`.

get_transform(transform_name)

Must return the lookup named `transform_name`. For instance, by returning `self.output_field.get_transform(transform_name)`.

output_field

Defines the type of class returned by the `get_lookup()` method. It must be a [Field](#) instance.

Transform reference

class Transform

A `Transform` is a generic class to implement field transformations. A prominent example is `__year` that transforms a `DateField` into a `IntegerField`.

The notation to use a `Transform` in a lookup expression is `<expression>__<transformation>` (e.g. `date__year`).

This class follows the [Query Expression API](#), which implies that you can use `<expression>__<transform1>__<transform2>`. It's a specialized `Func()` expression that only accepts one argument. It can also be used on the right hand side of a filter or directly as an annotation.

bilateral

A boolean indicating whether this transformation should apply to both `lhs` and `rhs`. Bilateral transformations will be applied to `rhs` in the same order as they appear in the lookup expression. By default it is set to `False`. For example usage, see [How to write custom lookups](#).

lhs

The left-hand side - what is being transformed. It must follow the [Query Expression API](#).

lookup_name

The name of the lookup, used for identifying it on parsing query expressions. It cannot contain the string `"__"`.

output_field

Defines the class this transformation outputs. It must be a *Field* instance. By default is the same as its `lhs.output_field`.

Lookup reference**class Lookup**

A *Lookup* is a generic class to implement lookups. A lookup is a query expression with a left-hand side, *lhs*; a right-hand side, *rhs*; and a `lookup_name` that is used to produce a boolean comparison between *lhs* and *rhs* such as `lhs in rhs` or `lhs > rhs`.

The primary notation to use a lookup in an expression is `<lhs>__<lookup_name>=<rhs>`. Lookups can also be used directly in *QuerySet* filters:

```
Book.objects.filter(LessThan(F("word_count"), 7500))
```

...or annotations:

```
Book.objects.annotate(is_short_story=LessThan(F("word_count"), 7500))
```

lhs

The left-hand side - what is being looked up. The object typically follows the [Query Expression API](#). It may also be a plain value.

rhs

The right-hand side - what *lhs* is being compared against. It can be a plain value, or something that compiles into SQL, typically an *F()* object or a *QuerySet*.

lookup_name

The name of this lookup, used to identify it on parsing query expressions. It cannot contain the string `"__"`.

process_lhs(compiler, connection, lhs=None)

Returns a tuple (*lhs_string*, *lhs_params*), as returned by `compiler.compile(lhs)`. This method can be overridden to tune how the *lhs* is processed.

compiler is an *SQLCompiler* object, to be used like `compiler.compile(lhs)` for compiling *lhs*. The *connection* can be used for compiling vendor specific SQL. If *lhs* is not *None*, use it as the processed *lhs* instead of `self.lhs`.

process_rhs(compiler, connection)

Behaves the same way as *process_lhs()*, for the right-hand side.

6.16.12 Query Expressions

Query expressions describe a value or a computation that can be used as part of an update, create, filter, order by, annotation, or aggregate. When an expression outputs a boolean value, it may be used directly in filters. There are a number of built-in expressions (documented below) that can be used to help you write queries. Expressions can be combined, or in some cases nested, to form more complex computations.

Supported arithmetic

Django supports negation, addition, subtraction, multiplication, division, modulo arithmetic, and the power operator on query expressions, using Python constants, variables, and even other expressions.

Output field

Many of the expressions documented in this section support an optional `output_field` parameter. If given, Django will load the value into that field after retrieving it from the database.

`output_field` takes a model field instance, like `IntegerField()` or `BooleanField()`. Usually, the field doesn't need any arguments, like `max_length`, since field arguments relate to data validation which will not be performed on the expression's output value.

`output_field` is only required when Django is unable to automatically determine the result's field type, such as complex expressions that mix field types. For example, adding a `DecimalField()` and a `FloatField()` requires an output field, like `output_field=FloatField()`.

Some examples

```
>>> from django.db.models import Count, F, Value
>>> from django.db.models.functions import Length, Upper
>>> from django.db.models.lookups import GreaterThan

# Find companies that have more employees than chairs.
>>> Company.objects.filter(num_employees__gt=F("num_chairs"))

# Find companies that have at least twice as many employees
# as chairs. Both the querysets below are equivalent.
>>> Company.objects.filter(num_employees__gt=F("num_chairs") * 2)
>>> Company.objects.filter(num_employees__gt=F("num_chairs") + F("num_chairs"))

# How many chairs are needed for each company to seat all employees?
>>> company = (
...     Company.objects.filter(num_employees__gt=F("num_chairs"))
...     .annotate(chairs_needed=F("num_employees") - F("num_chairs"))
```

(continues on next page)

(continued from previous page)

```
...     .first()
... )
>>> company.num_employees
120
>>> company.num_chairs
50
>>> company.chairs_needed
70

# Create a new company using expressions.
>>> company = Company.objects.create(name="Google", ticker=Upper(Value("goog")))
# Be sure to refresh it if you need to access the field.
>>> company.refresh_from_db()
>>> company.ticker
'GOOG'

# Annotate models with an aggregated value. Both forms
# below are equivalent.
Company.objects.annotate(num_products=Count('products'))
Company.objects.annotate(num_products=Count(F('products')))

# Aggregates can contain complex computations also
Company.objects.annotate(num_offerings=Count(F('products') + F('services')))

# Expressions can also be used in order_by(), either directly
Company.objects.order_by(Length('name').asc())
Company.objects.order_by(Length('name').desc())
# or using the double underscore lookup syntax.
from django.db.models import CharField
from django.db.models.functions import Length
CharField.register_lookup(Length)
Company.objects.order_by('name__length')

# Boolean expression can be used directly in filters.
from django.db.models import Exists
Company.objects.filter(
    Exists(Employee.objects.filter(company=OuterRef('pk'), salary__gt=10))
)

# Lookup expressions can also be used directly in filters
Company.objects.filter(GreaterThan(F('num_employees'), F('num_chairs')))
# or annotations.
Company.objects.annotate(
```

(continues on next page)

(continued from previous page)

```

    need_chairs=GreaterThan(F('num_employees'), F('num_chairs')),
)

```

Built-in Expressions

Note: These expressions are defined in `django.db.models.expressions` and `django.db.models.aggregates`, but for convenience they're available and usually imported from `django.db.models`.

F() expressions

class F

An `F()` object represents the value of a model field, transformed value of a model field, or annotated column. It makes it possible to refer to model field values and perform database operations using them without actually having to pull them out of the database into Python memory.

Instead, Django uses the `F()` object to generate an SQL expression that describes the required operation at the database level.

Let's try this with an example. Normally, one might do something like this:

```

# Tintin filed a news story!
reporter = Reporters.objects.get(name="Tintin")
reporter.stories_filed += 1
reporter.save()

```

Here, we have pulled the value of `reporter.stories_filed` from the database into memory and manipulated it using familiar Python operators, and then saved the object back to the database. But instead we could also have done:

```

from django.db.models import F

reporter = Reporters.objects.get(name="Tintin")
reporter.stories_filed = F("stories_filed") + 1
reporter.save()

```

Although `reporter.stories_filed = F('stories_filed') + 1` looks like a normal Python assignment of value to an instance attribute, in fact it's an SQL construct describing an operation on the database.

When Django encounters an instance of `F()`, it overrides the standard Python operators to create an encapsulated SQL expression; in this case, one which instructs the database to increment the database field represented by `reporter.stories_filed`.

Whatever value is or was on `reporter.stories_filed`, Python never gets to know about it - it is dealt with entirely by the database. All Python does, through Django's `F()` class, is create the SQL syntax to refer to the field and describe the operation.

To access the new value saved this way, the object must be reloaded:

```
reporter = Reporters.objects.get(pk=reporter.pk)
# Or, more succinctly:
reporter.refresh_from_db()
```

As well as being used in operations on single instances as above, `F()` can be used on `QuerySets` of object instances, with `update()`. This reduces the two queries we were using above - the `get()` and the `save()` - to just one:

```
reporter = Reporters.objects.filter(name="Tintin")
reporter.update(stories_filed=F("stories_filed") + 1)
```

We can also use `update()` to increment the field value on multiple objects - which could be very much faster than pulling them all into Python from the database, looping over them, incrementing the field value of each one, and saving each one back to the database:

```
Reporter.objects.update(stories_filed=F("stories_filed") + 1)
```

`F()` therefore can offer performance advantages by:

- getting the database, rather than Python, to do work
- reducing the number of queries some operations require

Avoiding race conditions using `F()`

Another useful benefit of `F()` is that having the database - rather than Python - update a field's value avoids a race condition.

If two Python threads execute the code in the first example above, one thread could retrieve, increment, and save a field's value after the other has retrieved it from the database. The value that the second thread saves will be based on the original value; the work of the first thread will be lost.

If the database is responsible for updating the field, the process is more robust: it will only ever update the field based on the value of the field in the database when the `save()` or `update()` is executed, rather than based on its value when the instance was retrieved.

F() assignments persist after Model.save()

F() objects assigned to model fields persist after saving the model instance and will be applied on each `save()`. For example:

```
reporter = Reporters.objects.get(name="Tintin")
reporter.stories_filed = F("stories_filed") + 1
reporter.save()

reporter.name = "Tintin Jr."
reporter.save()
```

`stories_filed` will be updated twice in this case. If it's initially 1, the final value will be 3. This persistence can be avoided by reloading the model object after saving it, for example, by using `refresh_from_db()`.

Using F() in filters

F() is also very useful in `QuerySet` filters, where they make it possible to filter a set of objects against criteria based on their field values, rather than on Python values.

This is documented in [using F\(\) expressions in queries](#).

Using F() with annotations

F() can be used to create dynamic fields on your models by combining different fields with arithmetic:

```
company = Company.objects.annotate(chairs_needed=F("num_employees") - F("num_chairs"))
```

If the fields that you're combining are of different types you'll need to tell Django what kind of field will be returned. Most expressions support `output_field` for this case, but since F() does not, you will need to wrap the expression with `ExpressionWrapper`:

```
from django.db.models import DateTimeField, ExpressionWrapper, F

Ticket.objects.annotate(
    expires=ExpressionWrapper(
        F("active_at") + F("duration"), output_field=DateTimeField()
    )
)
```

When referencing relational fields such as `ForeignKey`, F() returns the primary key value rather than a model instance:

```
>> car = Company.objects.annotate(built_by=F('manufacturer'))[0]
>> car.manufacturer
<Manufacturer: Toyota>
>> car.built_by
3
```

Using F() to sort null values

Use F() and the `nulls_first` or `nulls_last` keyword argument to *Expression.asc()* or *desc()* to control the ordering of a field's null values. By default, the ordering depends on your database.

For example, to sort companies that haven't been contacted (`last_contacted` is null) after companies that have been contacted:

```
from django.db.models import F

Company.objects.order_by(F("last_contacted").desc(nulls_last=True))
```

Using F() with logical operations

F() expressions that output BooleanField can be logically negated with the inversion operator `~F()`. For example, to swap the activation status of companies:

```
from django.db.models import F

Company.objects.update(is_active=~F("is_active"))
```

Func() expressions

Func() expressions are the base type of all expressions that involve database functions like COALESCE and LOWER, or aggregates like SUM. They can be used directly:

```
from django.db.models import F, Func

queryset.annotate(field_lower=Func(F("field"), function="LOWER"))
```

or they can be used to build a library of database functions:

```
class Lower(Func):
    function = "LOWER"
```

(continues on next page)

(continued from previous page)

```
queryset.annotate(field_lower=Lower("field"))
```

But both cases will result in a queryset where each model is annotated with an extra attribute `field_lower` produced, roughly, from the following SQL:

```
SELECT
...
LOWER("db_table"."field") as "field_lower"
```

See [Database Functions](#) for a list of built-in database functions.

The `Func` API is as follows:

```
class Func(*expressions, **extra)
```

function

A class attribute describing the function that will be generated. Specifically, the `function` will be interpolated as the `function` placeholder within `template`. Defaults to `None`.

template

A class attribute, as a format string, that describes the SQL that is generated for this function. Defaults to `'%(function)s(%(expressions)s)'`.

If you're constructing SQL like `strftime('%W', 'date')` and need a literal `%` character in the query, quadruple it (`%%`) in the `template` attribute because the string is interpolated twice: once during the template interpolation in `as_sql()` and once in the SQL interpolation with the query parameters in the database cursor.

arg_joiner

A class attribute that denotes the character used to join the list of `expressions` together. Defaults to `','`.

arity

A class attribute that denotes the number of arguments the function accepts. If this attribute is set and the function is called with a different number of expressions, `TypeError` will be raised. Defaults to `None`.

```
as_sql(compiler, connection, function=None, template=None, arg_joiner=None, **extra_context)
```

Generates the SQL fragment for the database function. Returns a tuple `(sql, params)`, where `sql` is the SQL string, and `params` is the list or tuple of query parameters.

The `as_vendor()` methods should use the `function`, `template`, `arg_joiner`, and any other `**extra_context` parameters to customize the SQL as needed. For example:

Listing 13: `django/db/models/functions.py`

```
class ConcatPair(Func):
    ...
    function = "CONCAT"
    ...

    def as_mysql(self, compiler, connection, **extra_context):
        return super().as_sql(
            compiler,
            connection,
            function="CONCAT_WS",
            template="%(function)s(' ', %(expressions)s)",
            **extra_context
        )
```

To avoid an SQL injection vulnerability, `extra_context` [must not contain untrusted user input](#) as these values are interpolated into the SQL string rather than passed as query parameters, where the database driver would escape them.

The `*expressions` argument is a list of positional expressions that the function will be applied to. The expressions will be converted to strings, joined together with `arg_joiner`, and then interpolated into the `template` as the `expressions` placeholder.

Positional arguments can be expressions or Python values. Strings are assumed to be column references and will be wrapped in `F()` expressions while other values will be wrapped in `Value()` expressions.

The `**extra` kwargs are `key=value` pairs that can be interpolated into the `template` attribute. To avoid an SQL injection vulnerability, `extra` [must not contain untrusted user input](#) as these values are interpolated into the SQL string rather than passed as query parameters, where the database driver would escape them.

The `function`, `template`, and `arg_joiner` keywords can be used to replace the attributes of the same name without having to define your own class. [output_field](#) can be used to define the expected return type.

Aggregate() expressions

An aggregate expression is a special case of a [Func\(\) expression](#) that informs the query that a `GROUP BY` clause is required. All of the [aggregate functions](#), like `Sum()` and `Count()`, inherit from `Aggregate()`.

Since `Aggregates` are expressions and wrap expressions, you can represent some complex computations:

```
from django.db.models import Count

Company.objects.annotate(
```

(continues on next page)

(continued from previous page)

```
managers_required=(Count("num_employees") / 4) + Count("num_managers")
)
```

The `Aggregate` API is as follows:

```
class Aggregate(*expressions, output_field=None, distinct=False, filter=None, default=None, **extra)
```

`template`

A class attribute, as a format string, that describes the SQL that is generated for this aggregate. Defaults to `'%(function)s%(distinct)s%(expressions)s'`.

`function`

A class attribute describing the aggregate function that will be generated. Specifically, the function will be interpolated as the function placeholder within `template`. Defaults to `None`.

`window_compatible`

Defaults to `True` since most aggregate functions can be used as the source expression in *Window*.

`allow_distinct`

A class attribute determining whether or not this aggregate function allows passing a `distinct` keyword argument. If set to `False` (default), `TypeError` is raised if `distinct=True` is passed.

`empty_result_set_value`

Defaults to `None` since most aggregate functions result in `NULL` when applied to an empty result set.

The `expressions` positional arguments can include expressions, transforms of the model field, or the names of model fields. They will be converted to a string and used as the `expressions` placeholder within the `template`.

The `distinct` argument determines whether or not the aggregate function should be invoked for each distinct value of `expressions` (or set of values, for multiple `expressions`). The argument is only supported on aggregates that have `allow_distinct` set to `True`.

The `filter` argument takes a *Q object* that's used to filter the rows that are aggregated. See [Conditional aggregation](#) and [Filtering on annotations](#) for example usage.

The `default` argument takes a value that will be passed along with the aggregate to *Coalesce*. This is useful for specifying a value to be returned other than `None` when the queryset (or grouping) contains no entries.

The `**extra` kwargs are `key=value` pairs that can be interpolated into the `template` attribute.

Creating your own Aggregate Functions

You can create your own aggregate functions, too. At a minimum, you need to define `function`, but you can also completely customize the SQL that is generated. Here's a brief example:

```
from django.db.models import Aggregate

class Sum(Aggregate):
    # Supports SUM(ALL field).
    function = "SUM"
    template = "%(function)s(%(all_values)s%(expressions)s)"
    allow_distinct = False

    def __init__(self, expression, all_values=False, **extra):
        super().__init__(expression, all_values="ALL " if all_values else "", **extra)
```

Value() expressions

```
class Value(value, output_field=None)
```

A `Value()` object represents the smallest possible component of an expression: a simple value. When you need to represent the value of an integer, boolean, or string within an expression, you can wrap that value within a `Value()`.

You will rarely need to use `Value()` directly. When you write the expression `F('field') + 1`, Django implicitly wraps the `1` in a `Value()`, allowing simple values to be used in more complex expressions. You will need to use `Value()` when you want to pass a string to an expression. Most expressions interpret a string argument as the name of a field, like `Lower('name')`.

The `value` argument describes the value to be included in the expression, such as `1`, `True`, or `None`. Django knows how to convert these Python values into their corresponding database type.

If no `output_field` is specified, it will be inferred from the type of the provided `value` for many common types. For example, passing an instance of `datetime.datetime` as `value` defaults `output_field` to `DateTimeField`.

ExpressionWrapper() expressions

```
class ExpressionWrapper(expression, output_field)
```

`ExpressionWrapper` surrounds another expression and provides access to properties, such as `output_field`, that may not be available on other expressions. `ExpressionWrapper` is necessary when using arithmetic on `F()` expressions with different types as described in [Using F\(\) with annotations](#).

Conditional expressions

Conditional expressions allow you to use `if ... elif ... else` logic in queries. Django natively supports SQL CASE expressions. For more details see [Conditional Expressions](#).

Subquery() expressions

```
class Subquery(queryset, output_field=None)
```

You can add an explicit subquery to a `QuerySet` using the `Subquery` expression.

For example, to annotate each post with the email address of the author of the newest comment on that post:

```
>>> from django.db.models import OuterRef, Subquery
>>> newest = Comment.objects.filter(post=OuterRef("pk")).order_by("-created_at")
>>> Post.objects.annotate(newest_commenter_email=Subquery(newest.values("email")[:1]))
```

On PostgreSQL, the SQL looks like:

```
SELECT "post"."id", (
    SELECT UO."email"
    FROM "comment" UO
    WHERE UO."post_id" = ("post"."id")
    ORDER BY UO."created_at" DESC LIMIT 1
) AS "newest_commenter_email" FROM "post"
```

Note: The examples in this section are designed to show how to force Django to execute a subquery. In some cases it may be possible to write an equivalent queryset that performs the same task more clearly or efficiently.

Referencing columns from the outer queryset

```
class OuterRef(field)
```

Use `OuterRef` when a queryset in a `Subquery` needs to refer to a field from the outer query or its transform. It acts like an *F* expression except that the check to see if it refers to a valid field isn't made until the outer queryset is resolved.

Instances of `OuterRef` may be used in conjunction with nested instances of `Subquery` to refer to a containing queryset that isn't the immediate parent. For example, this queryset would need to be within a nested pair of `Subquery` instances to resolve correctly:

```
>>> Book.objects.filter(author=OuterRef(OuterRef("pk")))
```

Limiting a subquery to a single column

There are times when a single column must be returned from a Subquery, for instance, to use a Subquery as the target of an `__in` lookup. To return all comments for posts published within the last day:

```
>>> from datetime import timedelta
>>> from django.utils import timezone
>>> one_day_ago = timezone.now() - timedelta(days=1)
>>> posts = Post.objects.filter(published_at__gte=one_day_ago)
>>> Comment.objects.filter(post__in=Subquery(posts.values("pk")))
```

In this case, the subquery must use `values()` to return only a single column: the primary key of the post.

Limiting the subquery to a single row

To prevent a subquery from returning multiple rows, a slice (`[ :1 ]`) of the queryset is used:

```
>>> subquery = Subquery(newest.values("email")[ :1 ])
>>> Post.objects.annotate(newest_commenter_email=subquery)
```

In this case, the subquery must only return a single column and a single row: the email address of the most recently created comment.

(Using `get()` instead of a slice would fail because the `OuterRef` cannot be resolved until the queryset is used within a Subquery.)

Exists() subqueries

```
class Exists(queryset)
```

`Exists` is a Subquery subclass that uses an SQL EXISTS statement. In many cases it will perform better than a subquery since the database is able to stop evaluation of the subquery when a first matching row is found.

For example, to annotate each post with whether or not it has a comment from within the last day:

```
>>> from django.db.models import Exists, OuterRef
>>> from datetime import timedelta
>>> from django.utils import timezone
>>> one_day_ago = timezone.now() - timedelta(days=1)
>>> recent_comments = Comment.objects.filter(
...     post=OuterRef("pk"),
```

(continues on next page)

(continued from previous page)

```
...     created_at__gte=one_day_ago,
... )
>>> Post.objects.annotate(recent_comment=Exists(recent_comments))
```

On PostgreSQL, the SQL looks like:

```
SELECT "post"."id", "post"."published_at", EXISTS(
    SELECT (1) as "a"
    FROM "comment" UO
    WHERE (
        UO."created_at" >= YYYY-MM-DD HH:MM:SS AND
        UO."post_id" = "post"."id"
    )
    LIMIT 1
) AS "recent_comment" FROM "post"
```

It's unnecessary to force `Exists` to refer to a single column, since the columns are discarded and a boolean result is returned. Similarly, since ordering is unimportant within an SQL `EXISTS` subquery and would only degrade performance, it's automatically removed.

You can query using `NOT EXISTS` with `~Exists()`.

Filtering on a Subquery() or Exists() expressions

`Subquery()` that returns a boolean value and `Exists()` may be used as a condition in *when* expressions, or to directly filter a queryset:

```
>>> recent_comments = Comment.objects.filter(...) # From above
>>> Post.objects.filter(Exists(recent_comments))
```

This will ensure that the subquery will not be added to the `SELECT` columns, which may result in a better performance.

Using aggregates within a Subquery expression

Aggregates may be used within a Subquery, but they require a specific combination of *filter()*, *values()*, and *annotate()* to get the subquery grouping correct.

Assuming both models have a `length` field, to find posts where the post length is greater than the total length of all combined comments:

```
>>> from django.db.models import OuterRef, Subquery, Sum
>>> comments = Comment.objects.filter(post=OuterRef("pk")).order_by().values("post")
```

(continues on next page)

(continued from previous page)

```
>>> total_comments = comments.annotate(total=Sum("length")).values("total")
>>> Post.objects.filter(length__gt=Subquery(total_comments))
```

The initial `filter(...)` limits the subquery to the relevant parameters. `order_by()` removes the default *ordering* (if any) on the `Comment` model. `values('post')` aggregates comments by `Post`. Finally, `annotate(...)` performs the aggregation. The order in which these queryset methods are applied is important. In this case, since the subquery must be limited to a single column, `values('total')` is required.

This is the only way to perform an aggregation within a `Subquery`, as using *aggregate()* attempts to evaluate the queryset (and if there is an `OuterRef`, this will not be possible to resolve).

Raw SQL expressions

```
class RawSQL(sql, params, output_field=None)
```

Sometimes database expressions can't easily express a complex `WHERE` clause. In these edge cases, use the `RawSQL` expression. For example:

```
>>> from django.db.models.expressions import RawSQL
>>> queryset.annotate(val=RawSQL("select col from sometable where othercol = %s", (param,)))
```

These extra lookups may not be portable to different database engines (because you're explicitly writing SQL code) and violate the DRY principle, so you should avoid them if possible.

`RawSQL` expressions can also be used as the target of `__in` filters:

```
>>> queryset.filter(id__in=RawSQL("select id from sometable where col = %s", (param,)))
```

Warning: To protect against *SQL injection attacks*, you must escape any parameters that the user can control by using `params`. `params` is a required argument to force you to acknowledge that you're not interpolating your SQL with user-provided data.

You also must not quote placeholders in the SQL string. This example is vulnerable to SQL injection because of the quotes around `%s`:

```
RawSQL("select col from sometable where othercol = '%s'") # unsafe!
```

You can read more about how Django's *SQL injection protection* works.

Window functions

Window functions provide a way to apply functions on partitions. Unlike a normal aggregation function which computes a final result for each set defined by the group by, window functions operate on [frames](#) and partitions, and compute the result for each row.

You can specify multiple windows in the same query which in Django ORM would be equivalent to including multiple expressions in a [QuerySet.annotate\(\)](#) call. The ORM doesn't make use of named windows, instead they are part of the selected columns.

```
class Window(expression, partition_by=None, order_by=None, frame=None, output_field=None)
```

template

Defaults to `%(expression)s OVER (%(window)s)'`. If only the `expression` argument is provided, the window clause will be blank.

The `Window` class is the main expression for an `OVER` clause.

The `expression` argument is either a [window function](#), an [aggregate function](#), or an expression that's compatible in a window clause.

The `partition_by` argument accepts an expression or a sequence of expressions (column names should be wrapped in an `F`-object) that control the partitioning of the rows. Partitioning narrows which rows are used to compute the result set.

The `output_field` is specified either as an argument or by the expression.

The `order_by` argument accepts an expression on which you can call [asc\(\)](#) and [desc\(\)](#), a string of a field name (with an optional `"-"` prefix which indicates descending order), or a tuple or list of strings and/or expressions. The ordering controls the order in which the expression is applied. For example, if you sum over the rows in a partition, the first result is the value of the first row, the second is the sum of first and second row.

The `frame` parameter specifies which other rows that should be used in the computation. See [Frames](#) for details.

Support for `order_by` by field name references was added.

For example, to annotate each movie with the average rating for the movies by the same studio in the same genre and release year:

```
>>> from django.db.models import Avg, F, Window
>>> Movie.objects.annotate(
...     avg_rating=Window(
...         expression=Avg("rating"),
...         partition_by=[F("studio"), F("genre")],
...         order_by="released__year",
```

(continues on next page)

(continued from previous page)

```
...     ),  
... )
```

This allows you to check if a movie is rated better or worse than its peers.

You may want to apply multiple expressions over the same window, i.e., the same partition and frame. For example, you could modify the previous example to also include the best and worst rating in each movie's group (same studio, genre, and release year) by using three window functions in the same query. The partition and ordering from the previous example is extracted into a dictionary to reduce repetition:

```
>>> from django.db.models import Avg, F, Max, Min, Window  
>>> window = {  
...     "partition_by": [F("studio"), F("genre")],  
...     "order_by": "released__year",  
... }  
>>> Movie.objects.annotate(  
...     avg_rating=Window(  
...         expression=Avg("rating"),  
...         **window,  
...     ),  
...     best=Window(  
...         expression=Max("rating"),  
...         **window,  
...     ),  
...     worst=Window(  
...         expression=Min("rating"),  
...         **window,  
...     ),  
... )
```

Filtering against window functions is supported as long as lookups are not disjunctive (not using OR or XOR as a connector) and against a queryset performing aggregation.

For example, a query that relies on aggregation and has an OR-ed filter against a window function and a field is not supported. Applying combined predicates post-aggregation could cause rows that would normally be excluded from groups to be included:

```
>>> qs = Movie.objects.annotate(  
...     category_rank=Window(Rank(), partition_by="category", order_by="-rating"),  
...     scenes_count=Count("actors"),  
... ).filter(Q(category_rank__lte=3) | Q(title__contains="Batman"))  
>>> list(qs)  
NotImplementedError: Heterogeneous disjunctive predicates against window functions  
are not implemented when performing conditional aggregation.
```

Support for filtering against window functions was added.

Among Django's built-in database backends, MySQL 8.0.2+, PostgreSQL, and Oracle support window expressions. Support for different window expression features varies among the different databases. For example, the options in `asc()` and `desc()` may not be supported. Consult the documentation for your database as needed.

Frames

For a window frame, you can choose either a range-based sequence of rows or an ordinary sequence of rows.

```
class ValueRange(start=None, end=None)
```

frame_type

This attribute is set to 'RANGE'.

PostgreSQL has limited support for `ValueRange` and only supports use of the standard start and end points, such as `CURRENT ROW` and `UNBOUNDED FOLLOWING`.

```
class RowRange(start=None, end=None)
```

frame_type

This attribute is set to 'ROWS'.

Both classes return SQL with the template:

```
%(frame_type)s BETWEEN %(start)s AND %(end)s
```

Frames narrow the rows that are used for computing the result. They shift from some start point to some specified end point. Frames can be used with and without partitions, but it's often a good idea to specify an ordering of the window to ensure a deterministic result. In a frame, a peer in a frame is a row with an equivalent value, or all rows if an ordering clause isn't present.

The default starting point for a frame is `UNBOUNDED PRECEDING` which is the first row of the partition. The end point is always explicitly included in the SQL generated by the ORM and is by default `UNBOUNDED FOLLOWING`. The default frame includes all rows from the partition to the last row in the set.

The accepted values for the `start` and `end` arguments are `None`, an integer, or zero. A negative integer for `start` results in `N preceding`, while `None` yields `UNBOUNDED PRECEDING`. For both `start` and `end`, zero will return `CURRENT ROW`. Positive integers are accepted for `end`.

There's a difference in what `CURRENT ROW` includes. When specified in `ROWS` mode, the frame starts or ends with the current row. When specified in `RANGE` mode, the frame starts or ends at the first or last peer according to the ordering clause. Thus, `RANGE CURRENT ROW` evaluates the expression for rows which have the same value specified by the ordering. Because the template includes both the `start` and `end` points, this may be expressed with:

```
ValueRange(start=0, end=0)
```

If a movie's "peers" are described as movies released by the same studio in the same genre in the same year, this `RowRange` example annotates each movie with the average rating of a movie's two prior and two following peers:

```
>>> from django.db.models import Avg, F, RowRange, Window
>>> Movie.objects.annotate(
...     avg_rating=Window(
...         expression=Avg("rating"),
...         partition_by=[F("studio"), F("genre")],
...         order_by="released__year",
...         frame=RowRange(start=-2, end=2),
...     ),
... )
```

If the database supports it, you can specify the start and end points based on values of an expression in the partition. If the `released` field of the `Movie` model stores the release month of each movies, this `ValueRange` example annotates each movie with the average rating of a movie's peers released between twelve months before and twelve months after the each movie:

```
>>> from django.db.models import Avg, F, ValueRange, Window
>>> Movie.objects.annotate(
...     avg_rating=Window(
...         expression=Avg("rating"),
...         partition_by=[F("studio"), F("genre")],
...         order_by="released__year",
...         frame=ValueRange(start=-12, end=12),
...     ),
... )
```

Technical Information

Below you'll find technical implementation details that may be useful to library authors. The technical API and examples below will help with creating generic query expressions that can extend the built-in functionality that Django provides.

Expression API

Query expressions implement the [query expression API](#), but also expose a number of extra methods and attributes listed below. All query expressions must inherit from `Expression()` or a relevant subclass.

When a query expression wraps another expression, it is responsible for calling the appropriate methods on the wrapped expression.

class Expression

contains_aggregate

Tells Django that this expression contains an aggregate and that a `GROUP BY` clause needs to be added to the query.

contains_over_clause

Tells Django that this expression contains a [Window](#) expression. It's used, for example, to disallow window function expressions in queries that modify data.

filterable

Tells Django that this expression can be referenced in [QuerySet.filter\(\)](#). Defaults to `True`.

window_compatible

Tells Django that this expression can be used as the source expression in [Window](#). Defaults to `False`.

empty_result_set_value

Tells Django which value should be returned when the expression is used to apply a function over an empty result set. Defaults to `NotImplemented` which forces the expression to be computed on the database.

resolve_expression(query=None, allow_joins=True, reuse=None, summarize=False, for_save=False)

Provides the chance to do any preprocessing or validation of the expression before it's added to the query. `resolve_expression()` must also be called on any nested expressions. A `copy()` of `self` should be returned with any necessary transformations.

`query` is the backend query implementation.

`allow_joins` is a boolean that allows or denies the use of joins in the query.

`reuse` is a set of reusable joins for multi-join scenarios.

`summarize` is a boolean that, when `True`, signals that the query being computed is a terminal aggregate query.

`for_save` is a boolean that, when `True`, signals that the query being executed is performing a create or update.

get_source_expressions()

Returns an ordered list of inner expressions. For example:

```
>>> Sum(F("foo")).get_source_expressions()
[F('foo')]
```

set_source_expressions(expressions)

Takes a list of expressions and stores them such that `get_source_expressions()` can return them.

relabeled_clone(change_map)

Returns a clone (copy) of `self`, with any column aliases relabeled. Column aliases are renamed when subqueries are created. `relabeled_clone()` should also be called on any nested expressions and assigned to the clone.

`change_map` is a dictionary mapping old aliases to new aliases.

Example:

```
def relabeled_clone(self, change_map):
    clone = copy.copy(self)
    clone.expression = self.expression.relabeled_clone(change_map)
    return clone
```

convert_value(value, expression, connection)

A hook allowing the expression to coerce `value` into a more appropriate type.

`expression` is the same as `self`.

get_group_by_cols()

Responsible for returning the list of columns references by this expression. `get_group_by_cols()` should be called on any nested expressions. `F()` objects, in particular, hold a reference to a column.

The `alias=None` keyword argument was removed.

asc(nulls_first=None, nulls_last=None)

Returns the expression ready to be sorted in ascending order.

`nulls_first` and `nulls_last` define how null values are sorted. See [Using F\(\) to sort null values](#) for example usage.

In older versions, `nulls_first` and `nulls_last` defaulted to `False`.

Deprecated since version 4.1: Passing `nulls_first=False` or `nulls_last=False` to `asc()` is deprecated. Use `None` instead.

desc(nulls_first=None, nulls_last=None)

Returns the expression ready to be sorted in descending order.

`nulls_first` and `nulls_last` define how null values are sorted. See [Using F\(\) to sort null values](#) for example usage.

In older versions, `nulls_first` and `nulls_last` defaulted to `False`.

Deprecated since version 4.1: Passing `nulls_first=False` or `nulls_last=False` to `desc()` is deprecated. Use `None` instead.

`reverse_ordering()`

Returns `self` with any modifications required to reverse the sort order within an `order_by` call. As an example, an expression implementing `NULLS LAST` would change its value to be `NULLS FIRST`. Modifications are only required for expressions that implement sort order like `OrderBy`. This method is called when [`reverse\(\)`](#) is called on a queryset.

Writing your own Query Expressions

You can write your own query expression classes that use, and can integrate with, other query expressions. Let's step through an example by writing an implementation of the `COALESCE` SQL function, without using the built-in [`Func\(\)`](#) expressions.

The `COALESCE` SQL function is defined as taking a list of columns or values. It will return the first column or value that isn't `NULL`.

We'll start by defining the template to be used for SQL generation and an `__init__()` method to set some attributes:

```
import copy
from django.db.models import Expression

class Coalesce(Expression):
    template = "COALESCE( %(expressions)s )"

    def __init__(self, expressions, output_field):
        super().__init__(output_field=output_field)
        if len(expressions) < 2:
            raise ValueError("expressions must have at least 2 elements")
        for expression in expressions:
            if not hasattr(expression, "resolve_expression"):
                raise TypeError("%r is not an Expression" % expression)
        self.expressions = expressions
```

We do some basic validation on the parameters, including requiring at least 2 columns or values, and ensuring they are expressions. We are requiring `output_field` here so that Django knows what kind of model field to assign the eventual result to.

Now we implement the preprocessing and validation. Since we do not have any of our own validation at this point, we delegate to the nested expressions:

```
def resolve_expression(
    self, query=None, allow_joins=True, reuse=None, summarize=False, for_save=False
):
    c = self.copy()
    c.is_summary = summarize
    for pos, expression in enumerate(self.expressions):
        c.expressions[pos] = expression.resolve_expression(
            query, allow_joins, reuse, summarize, for_save
        )
    return c
```

Next, we write the method responsible for generating the SQL:

```
def as_sql(self, compiler, connection, template=None):
    sql_expressions, sql_params = [], []
    for expression in self.expressions:
        sql, params = compiler.compile(expression)
        sql_expressions.append(sql)
        sql_params.extend(params)
    template = template or self.template
    data = {"expressions": ",".join(sql_expressions)}
    return template % data, sql_params

def as_oracle(self, compiler, connection):
    """
    Example of vendor specific handling (Oracle in this case).
    Let's make the function name lowercase.
    """
    return self.as_sql(compiler, connection, template="coalesce( %(expressions)s )")
```

`as_sql()` methods can support custom keyword arguments, allowing `as_vendorname()` methods to override data used to generate the SQL string. Using `as_sql()` keyword arguments for customization is preferable to mutating `self` within `as_vendorname()` methods as the latter can lead to errors when running on different database backends. If your class relies on class attributes to define data, consider allowing overrides in your `as_sql()` method.

We generate the SQL for each of the expressions by using the `compiler.compile()` method, and join the result together with commas. Then the template is filled out with our data and the SQL and parameters are returned.

We've also defined a custom implementation that is specific to the Oracle backend. The `as_oracle()` function will be called instead of `as_sql()` if the Oracle backend is in use.

Finally, we implement the rest of the methods that allow our query expression to play nice with other query expressions:

```
def get_source_expressions(self):
    return self.expressions

def set_source_expressions(self, expressions):
    self.expressions = expressions
```

Let's see how it works:

```
>>> from django.db.models import F, Value, CharField
>>> qs = Company.objects.annotate(
...     tagline=Coalesce(
...         [F("motto"), F("ticker_name"), F("description"), Value("No Tagline")],
...         output_field=CharField(),
...     )
... )
>>> for c in qs:
...     print("%s: %s" % (c.name, c.tagline))
...
Google: Do No Evil
Apple: AAPL
Yahoo: Internet Company
Django Software Foundation: No Tagline
```

Avoiding SQL injection

Since a Func's keyword arguments for `__init__()` (`**extra`) and `as_sql()` (`**extra_context`) are interpolated into the SQL string rather than passed as query parameters (where the database driver would escape them), they must not contain untrusted user input.

For example, if `substring` is user-provided, this function is vulnerable to SQL injection:

```
from django.db.models import Func

class Position(Func):
    function = "POSITION"
    template = "%(function)s('%(substring)s' in %(expressions)s)"

    def __init__(self, expression, substring):
        # substring=substring is an SQL injection vulnerability!
```

(continues on next page)

(continued from previous page)

```
super().__init__(expression, substring=substring)
```

This function generates an SQL string without any parameters. Since `substring` is passed to `super().__init__()` as a keyword argument, it's interpolated into the SQL string before the query is sent to the database.

Here's a corrected rewrite:

```
class Position(Func):
    function = "POSITION"
    arg_joiner = " IN "

    def __init__(self, expression, substring):
        super().__init__(substring, expression)
```

With `substring` instead passed as a positional argument, it'll be passed as a parameter in the database query.

Adding support in third-party database backends

If you're using a database backend that uses a different SQL syntax for a certain function, you can add support for it by monkey patching a new method onto the function's class.

Let's say we're writing a backend for Microsoft's SQL Server which uses the SQL `LEN` instead of `LENGTH` for the `Length` function. We'll monkey patch a new method called `as_sqlserver()` onto the `Length` class:

```
from django.db.models.functions import Length

def sqlserver_length(self, compiler, connection):
    return self.as_sql(compiler, connection, function="LEN")

Length.as_sqlserver = sqlserver_length
```

You can also customize the SQL using the `template` parameter of `as_sql()`.

We use `as_sqlserver()` because `django.db.connection.vendor` returns `sqlserver` for the backend.

Third-party backends can register their functions in the top level `__init__.py` file of the backend package or in a top level `expressions.py` file (or package) that is imported from the top level `__init__.py`.

For user projects wishing to patch the backend that they're using, this code should live in an `AppConfig.ready()` method.

6.16.13 Conditional Expressions

Conditional expressions let you use `if ... elif ... else` logic within filters, annotations, aggregations, and updates. A conditional expression evaluates a series of conditions for each row of a table and returns the matching result expression. Conditional expressions can also be combined and nested like other [expressions](#).

The conditional expression classes

We'll be using the following model in the subsequent examples:

```
from django.db import models

class Client(models.Model):
    REGULAR = "R"
    GOLD = "G"
    PLATINUM = "P"
    ACCOUNT_TYPE_CHOICES = [
        (REGULAR, "Regular"),
        (GOLD, "Gold"),
        (PLATINUM, "Platinum"),
    ]
    name = models.CharField(max_length=50)
    registered_on = models.DateField()
    account_type = models.CharField(
        max_length=1,
        choices=ACCOUNT_TYPE_CHOICES,
        default=REGULAR,
    )
```

When

```
class When(condition=None, then=None, **lookups)
```

A `When()` object is used to encapsulate a condition and its result for use in the conditional expression. Using a `When()` object is similar to using the `filter()` method. The condition can be specified using [field lookups](#), [Q](#) objects, or [Expression](#) objects that have an `output_field` that is a [BooleanField](#). The result is provided using the `then` keyword.

Some examples:

```
>>> from django.db.models import F, Q, When
>>> # String arguments refer to fields; the following two examples are equivalent:
```

(continues on next page)

(continued from previous page)

```
>>> When(account_type=Client.GOLD, then="name")
>>> When(account_type=Client.GOLD, then=F("name"))
>>> # You can use field lookups in the condition
>>> from datetime import date
>>> When(
...     registered_on__gt=date(2014, 1, 1),
...     registered_on__lt=date(2015, 1, 1),
...     then="account_type",
... )
>>> # Complex conditions can be created using Q objects
>>> When(Q(name__startswith="John") | Q(name__startswith="Paul"), then="name")
>>> # Condition can be created using boolean expressions.
>>> from django.db.models import Exists, OuterRef
>>> non_unique_account_type = (
...     Client.objects.filter(
...         account_type=OuterRef("account_type"),
...     )
...     .exclude(pk=OuterRef("pk"))
...     .values("pk")
... )
>>> When(Exists(non_unique_account_type), then=Value("non unique"))
>>> # Condition can be created using lookup expressions.
>>> from django.db.models.lookups import GreaterThan, LessThan
>>> When(
...     GreaterThan(F("registered_on"), date(2014, 1, 1))
...     & LessThan(F("registered_on"), date(2015, 1, 1)),
...     then="account_type",
... )
```

Keep in mind that each of these values can be an expression.

Note: Since the `then` keyword argument is reserved for the result of the `When()`, there is a potential conflict if a *Model* has a field named `then`. This can be resolved in two ways:

```
>>> When(then__exact=0, then=1)
>>> When(Q(then=0), then=1)
```

Case

```
class Case(*cases, **extra)
```

A `Case()` expression is like the `if ... elif ... else` statement in Python. Each condition in the provided `When()` objects is evaluated in order, until one evaluates to a truthful value. The `result` expression from the matching `When()` object is returned.

An example:

```
>>>
>>> from datetime import date, timedelta
>>> from django.db.models import Case, Value, When
>>> Client.objects.create(
...     name="Jane Doe",
...     account_type=Client.REGULAR,
...     registered_on=date.today() - timedelta(days=36),
... )
>>> Client.objects.create(
...     name="James Smith",
...     account_type=Client.GOLD,
...     registered_on=date.today() - timedelta(days=5),
... )
>>> Client.objects.create(
...     name="Jack Black",
...     account_type=Client.PLATINUM,
...     registered_on=date.today() - timedelta(days=10 * 365),
... )
>>> # Get the discount for each Client based on the account type
>>> Client.objects.annotate(
...     discount=Case(
...         When(account_type=Client.GOLD, then=Value("5%")),
...         When(account_type=Client.PLATINUM, then=Value("10%")),
...         default=Value("0%"),
...     ),
... ).values_list("name", "discount")
<QuerySet [('Jane Doe', '0%'), ('James Smith', '5%'), ('Jack Black', '10%')]>
```

`Case()` accepts any number of `When()` objects as individual arguments. Other options are provided using keyword arguments. If none of the conditions evaluate to `TRUE`, then the expression given with the `default` keyword argument is returned. If a `default` argument isn't provided, `None` is used.

If we wanted to change our previous query to get the discount based on how long the `Client` has been with us, we could do so using lookups:

```
>>> a_month_ago = date.today() - timedelta(days=30)
>>> a_year_ago = date.today() - timedelta(days=365)
>>> # Get the discount for each Client based on the registration date
>>> Client.objects.annotate(
...     discount=Case(
...         When(registered_on__lte=a_year_ago, then=Value("10%")),
...         When(registered_on__lte=a_month_ago, then=Value("5%")),
...         default=Value("0%"),
...     )
... ).values_list("name", "discount")
<QuerySet [('Jane Doe', '5%'), ('James Smith', '0%'), ('Jack Black', '10%')]>
```

Note: Remember that the conditions are evaluated in order, so in the above example we get the correct result even though the second condition matches both Jane Doe and Jack Black. This works just like an `if ... elif ... else` statement in Python.

`Case()` also works in a `filter()` clause. For example, to find gold clients that registered more than a month ago and platinum clients that registered more than a year ago:

```
>>> a_month_ago = date.today() - timedelta(days=30)
>>> a_year_ago = date.today() - timedelta(days=365)
>>> Client.objects.filter(
...     registered_on__lte=Case(
...         When(account_type=Client.GOLD, then=a_month_ago),
...         When(account_type=Client.PLATINUM, then=a_year_ago),
...     ),
... ).values_list("name", "account_type")
<QuerySet [('Jack Black', 'P')]>
```

Advanced queries

Conditional expressions can be used in annotations, aggregations, filters, lookups, and updates. They can also be combined and nested with other expressions. This allows you to make powerful conditional queries.

Conditional update

Let's say we want to change the `account_type` for our clients to match their registration dates. We can do this using a conditional expression and the `update()` method:

```
>>> a_month_ago = date.today() - timedelta(days=30)
>>> a_year_ago = date.today() - timedelta(days=365)
>>> # Update the account_type for each Client from the registration date
>>> Client.objects.update(
...     account_type=Case(
...         When(registered_on__lte=a_year_ago, then=Value(Client.PLATINUM)),
...         When(registered_on__lte=a_month_ago, then=Value(Client.GOLD)),
...         default=Value(Client.REGULAR),
...     ),
... )
>>> Client.objects.values_list("name", "account_type")
<QuerySet [('Jane Doe', 'G'), ('James Smith', 'R'), ('Jack Black', 'P')]>
```

Conditional aggregation

What if we want to find out how many clients there are for each `account_type`? We can use the `filter` argument of `aggregate functions` to achieve this:

```
>>> # Create some more Clients first so we can have something to count
>>> Client.objects.create(
...     name="Jean Grey", account_type=Client.REGULAR, registered_on=date.today()
... )
>>> Client.objects.create(
...     name="James Bond", account_type=Client.PLATINUM, registered_on=date.today()
... )
>>> Client.objects.create(
...     name="Jane Porter", account_type=Client.PLATINUM, registered_on=date.today()
... )
>>> # Get counts for each value of account_type
>>> from django.db.models import Count
>>> Client.objects.aggregate(
...     regular=Count("pk", filter=Q(account_type=Client.REGULAR)),
...     gold=Count("pk", filter=Q(account_type=Client.GOLD)),
...     platinum=Count("pk", filter=Q(account_type=Client.PLATINUM)),
... )
{'regular': 2, 'gold': 1, 'platinum': 3}
```

This aggregate produces a query with the SQL 2003 `FILTER WHERE` syntax on databases that support it:

```
SELECT count('id') FILTER (WHERE account_type=1) as regular,  
       count('id') FILTER (WHERE account_type=2) as gold,  
       count('id') FILTER (WHERE account_type=3) as platinum  
FROM clients;
```

On other databases, this is emulated using a CASE statement:

```
SELECT count(CASE WHEN account_type=1 THEN id ELSE null) as regular,  
       count(CASE WHEN account_type=2 THEN id ELSE null) as gold,  
       count(CASE WHEN account_type=3 THEN id ELSE null) as platinum  
FROM clients;
```

The two SQL statements are functionally equivalent but the more explicit FILTER may perform better.

Conditional filter

When a conditional expression returns a boolean value, it is possible to use it directly in filters. This means that it will not be added to the SELECT columns, but you can still use it to filter results:

```
>>> non_unique_account_type = (  
...     Client.objects.filter(  
...         account_type=OuterRef("account_type"),  
...     )  
...     .exclude(pk=OuterRef("pk"))  
...     .values("pk")  
... )  
>>> Client.objects.filter(~Exists(non_unique_account_type))
```

In SQL terms, that evaluates to:

```
SELECT ...  
FROM client c0  
WHERE NOT EXISTS (  
    SELECT c1.id  
    FROM client c1  
    WHERE c1.account_type = c0.account_type AND NOT c1.id = c0.id  
)
```

6.16.14 Database Functions

The classes documented below provide a way for users to use functions provided by the underlying database as annotations, aggregations, or filters in Django. Functions are also [expressions](#), so they can be used and combined with other expressions like [aggregate functions](#).

We’ ll be using the following model in examples of each function:

```
class Author(models.Model):
    name = models.CharField(max_length=50)
    age = models.PositiveIntegerField(null=True, blank=True)
    alias = models.CharField(max_length=50, null=True, blank=True)
    goes_by = models.CharField(max_length=50, null=True, blank=True)
```

We don’ t usually recommend allowing `null=True` for `CharField` since this allows the field to have two “empty values” , but it’ s important for the Coalesce example below.

Comparison and conversion functions

Cast

```
class Cast(expression, output_field)
```

Forces the result type of `expression` to be the one from `output_field`.

Usage example:

```
>>> from django.db.models import FloatField
>>> from django.db.models.functions import Cast
>>> Author.objects.create(age=25, name="Margaret Smith")
>>> author = Author.objects.annotate(
...     age_as_float=Cast("age", output_field=FloatField()),
... ).get()
>>> print(author.age_as_float)
25.0
```

Coalesce

```
class Coalesce(*expressions, **extra)
```

Accepts a list of at least two field names or expressions and returns the first non-null value (note that an empty string is not considered a null value). Each argument must be of a similar type, so mixing text and numbers will result in a database error.

Usage examples:

```
>>> # Get a screen name from least to most public
>>> from django.db.models import Sum
>>> from django.db.models.functions import Coalesce
>>> Author.objects.create(name="Margaret Smith", goes_by="Maggie")
>>> author = Author.objects.annotate(screen_name=Coalesce("alias", "goes_by", "name")).get()
>>> print(author.screen_name)
Maggie

>>> # Prevent an aggregate Sum() from returning None
>>> # The aggregate default argument uses Coalesce() under the hood.
>>> aggregated = Author.objects.aggregate(
...     combined_age=Sum("age"),
...     combined_age_default=Sum("age", default=0),
...     combined_age_coalesce=Coalesce(Sum("age"), 0),
... )
>>> print(aggregated["combined_age"])
None
>>> print(aggregated["combined_age_default"])
0
>>> print(aggregated["combined_age_coalesce"])
0
```

Warning: A Python value passed to `Coalesce` on MySQL may be converted to an incorrect type unless explicitly cast to the correct database type:

```
>>> from django.db.models import DateTimeField
>>> from django.db.models.functions import Cast, Coalesce
>>> from django.utils import timezone
>>> now = timezone.now()
>>> Coalesce('updated', Cast(now, DateTimeField()))
```

Collate

`class Collate(expression, collation)`

Takes an expression and a collation name to query against.

For example, to filter case-insensitively in SQLite:

```
>>> Author.objects.filter(name=Collate(Value("john"), "nocase"))
<QuerySet [<Author: John>, <Author: john>]>
```

It can also be used when ordering, for example with PostgreSQL:

```
>>> Author.objects.order_by(Collate("name", "et-x-icu"))
<QuerySet [<Author: Ursula>, <Author: Veronika>, <Author: Ülle>]>
```

Greatest

```
class Greatest(*expressions, **extra)
```

Accepts a list of at least two field names or expressions and returns the greatest value. Each argument must be of a similar type, so mixing text and numbers will result in a database error.

Usage example:

```
class Blog(models.Model):
    body = models.TextField()
    modified = models.DateTimeField(auto_now=True)

class Comment(models.Model):
    body = models.TextField()
    modified = models.DateTimeField(auto_now=True)
    blog = models.ForeignKey(Blog, on_delete=models.CASCADE)
```

```
>>> from django.db.models.functions import Greatest
>>> blog = Blog.objects.create(body="Greatest is the best.")
>>> comment = Comment.objects.create(body="No, Least is better.", blog=blog)
>>> comments = Comment.objects.annotate(last_updated=Greatest("modified", "blog__modified"))
>>> annotated_comment = comments.get()
```

`annotated_comment.last_updated` will be the most recent of `blog.modified` and `comment.modified`.

Warning: The behavior of `Greatest` when one or more expression may be null varies between databases:

- PostgreSQL: `Greatest` will return the largest non-null expression, or null if all expressions are null.
- SQLite, Oracle, and MySQL: If any expression is null, `Greatest` will return null.

The PostgreSQL behavior can be emulated using `Coalesce` if you know a sensible minimum value to provide as a default.

JSONObject

```
class JSONObject(**fields)
```

Takes a list of key-value pairs and returns a JSON object containing those pairs.

Usage example:

```
>>> from django.db.models import F
>>> from django.db.models.functions import JSONObject, Lower
>>> Author.objects.create(name="Margaret Smith", alias="msmith", age=25)
>>> author = Author.objects.annotate(
...     json_object=JSONObject(
...         name=Lower("name"),
...         alias="alias",
...         age=F("age") * 2,
...     )
... ).get()
>>> author.json_object
{'name': 'margaret smith', 'alias': 'msmith', 'age': 50}
```

Least

```
class Least(*expressions, **extra)
```

Accepts a list of at least two field names or expressions and returns the least value. Each argument must be of a similar type, so mixing text and numbers will result in a database error.

Warning: The behavior of `Least` when one or more expression may be `null` varies between databases:

- PostgreSQL: `Least` will return the smallest non-null expression, or `null` if all expressions are `null`.
- SQLite, Oracle, and MySQL: If any expression is `null`, `Least` will return `null`.

The PostgreSQL behavior can be emulated using `Coalesce` if you know a sensible maximum value to provide as a default.

NullIf

```
class NullIf(expression1, expression2)
```

Accepts two expressions and returns `None` if they are equal, otherwise returns `expression1`.

Caveats on Oracle

Due to an [Oracle convention](#), this function returns the empty string instead of `None` when the expressions are of type *CharField*.

Passing `Value(None)` to `expression1` is prohibited on Oracle since Oracle doesn't accept `NULL` as the first argument.

Date functions

We'll be using the following model in examples of each function:

```
class Experiment(models.Model):
    start_datetime = models.DateTimeField()
    start_date = models.DateField(null=True, blank=True)
    start_time = models.TimeField(null=True, blank=True)
    end_datetime = models.DateTimeField(null=True, blank=True)
    end_date = models.DateField(null=True, blank=True)
    end_time = models.TimeField(null=True, blank=True)
```

Extract

```
class Extract(expression, lookup_name=None, tzinfo=None, **extra)
```

Extracts a component of a date as a number.

Takes an `expression` representing a `DateField`, `DateTimeField`, `TimeField`, or `DurationField` and a `lookup_name`, and returns the part of the date referenced by `lookup_name` as an `IntegerField`. Django usually uses the databases' `extract` function, so you may use any `lookup_name` that your database supports. A `tzinfo` subclass, usually provided by [zoneinfo](#), can be passed to extract a value in a specific timezone.

Given the datetime `2015-06-15 23:30:01.000321+00:00`, the built-in `lookup_names` return:

- `"year"` : 2015
- `"iso_year"` : 2015
- `"quarter"` : 2
- `"month"` : 6

- “day” : 15
- “week” : 25
- “week_day” : 2
- “iso_week_day” : 1
- “hour” : 23
- “minute” : 30
- “second” : 1

If a different timezone like [Australia/Melbourne](#) is active in Django, then the datetime is converted to the timezone before the value is extracted. The timezone offset for Melbourne in the example date above is +10:00. The values returned when this timezone is active will be the same as above except for:

- “day” : 16
- “week_day” : 3
- “iso_week_day” : 2
- “hour” : 9

week_day values

The `week_day` lookup_type is calculated differently from most databases and from Python’s standard functions. This function will return 1 for Sunday, 2 for Monday, through 7 for Saturday.

The equivalent calculation in Python is:

```
>>> from datetime import datetime
>>> dt = datetime(2015, 6, 15)
>>> (dt.isoweekday() % 7) + 1
2
```

week values

The `week` lookup_type is calculated based on [ISO-8601](#), i.e., a week starts on a Monday. The first week of a year is the one that contains the year’s first Thursday, i.e. the first week has the majority (four or more) of its days in the year. The value returned is in the range 1 to 52 or 53.

Each `lookup_name` above has a corresponding `Extract` subclass (listed below) that should typically be used instead of the more verbose equivalent, e.g. use `ExtractYear(...)` rather than `Extract(..., lookup_name='year')`.

Usage example:

```

>>> from datetime import datetime
>>> from django.db.models.functions import Extract
>>> start = datetime(2015, 6, 15)
>>> end = datetime(2015, 7, 2)
>>> Experiment.objects.create(
...     start_datetime=start, start_date=start.date(), end_datetime=end, end_date=end.date()
... )
>>> # Add the experiment start year as a field in the QuerySet.
>>> experiment = Experiment.objects.annotate(
...     start_year=Extract("start_datetime", "year")
... ).get()
>>> experiment.start_year
2015
>>> # How many experiments completed in the same year in which they started?
>>> Experiment.objects.filter(start_datetime__year=Extract("end_datetime", "year")).count()
1

```

DateField extracts

```
class ExtractYear(expression, tzinfo=None, **extra)
```

```
    lookup_name = 'year'
```

```
class ExtractIsoYear(expression, tzinfo=None, **extra)
```

Returns the ISO-8601 week-numbering year.

```
    lookup_name = 'iso_year'
```

```
class ExtractMonth(expression, tzinfo=None, **extra)
```

```
    lookup_name = 'month'
```

```
class ExtractDay(expression, tzinfo=None, **extra)
```

```
    lookup_name = 'day'
```

```
class ExtractWeekDay(expression, tzinfo=None, **extra)
```

```
    lookup_name = 'week_day'
```

```
class ExtractIsoWeekDay(expression, tzinfo=None, **extra)
```

Returns the ISO-8601 week day with day 1 being Monday and day 7 being Sunday.

```
    lookup_name = 'iso_week_day'
```

```
class ExtractWeek(expression, tzinfo=None, **extra)
```

```
lookup_name = 'week'
```

```
class ExtractQuarter(expression, tzinfo=None, **extra)
```

```
lookup_name = 'quarter'
```

These are logically equivalent to `Extract('date_field', lookup_name)`. Each class is also a `Transform` registered on `DateField` and `DateTimeField` as `__(lookup_name)`, e.g. `__year`.

Since `DateFields` don't have a time component, only `Extract` subclasses that deal with date-parts can be used with `DateField`:

```
>>> from datetime import datetime, timezone
>>> from django.db.models.functions import (
...     ExtractDay,
...     ExtractMonth,
...     ExtractQuarter,
...     ExtractWeek,
...     ExtractIsoWeekDay,
...     ExtractWeekDay,
...     ExtractIsoYear,
...     ExtractYear,
... )
>>> start_2015 = datetime(2015, 6, 15, 23, 30, 1, tzinfo=timezone.utc)
>>> end_2015 = datetime(2015, 6, 16, 13, 11, 27, tzinfo=timezone.utc)
>>> Experiment.objects.create(
...     start_datetime=start_2015,
...     start_date=start_2015.date(),
...     end_datetime=end_2015,
...     end_date=end_2015.date(),
... )
>>> Experiment.objects.annotate(
...     year=ExtractYear("start_date"),
...     isoyear=ExtractIsoYear("start_date"),
...     quarter=ExtractQuarter("start_date"),
...     month=ExtractMonth("start_date"),
...     week=ExtractWeek("start_date"),
...     day=ExtractDay("start_date"),
...     weekday=ExtractWeekDay("start_date"),
...     isoweekday=ExtractIsoWeekDay("start_date"),
... ).values(
...     "year",
...     "isoyear",
...     "quarter",
...     "month",
...     "week",
```

(continues on next page)

(continued from previous page)

```

...     "day",
...     "weekday",
...     "isoweekday",
... ).get(
...     end_date__year=ExtractYear("start_date")
... )
{'year': 2015, 'isoyear': 2015, 'quarter': 2, 'month': 6, 'week': 25,
 'day': 15, 'weekday': 2, 'isoweekday': 1}

```

DateTimeField extracts

In addition to the following, all extracts for `DateField` listed above may also be used on `DateTimeFields`.

```

class ExtractHour(expression, tzinfo=None, **extra)

    lookup_name = 'hour'

class ExtractMinute(expression, tzinfo=None, **extra)

    lookup_name = 'minute'

class ExtractSecond(expression, tzinfo=None, **extra)

    lookup_name = 'second'

```

These are logically equivalent to `Extract('datetime_field', lookup_name)`. Each class is also a `Transform` registered on `DateTimeField` as `__(lookup_name)`, e.g. `__minute`.

`DateTimeField` examples:

```

>>> from datetime import datetime, timezone
>>> from django.db.models.functions import (
...     ExtractDay,
...     ExtractHour,
...     ExtractMinute,
...     ExtractMonth,
...     ExtractQuarter,
...     ExtractSecond,
...     ExtractWeek,
...     ExtractIsoWeekDay,
...     ExtractWeekDay,
...     ExtractIsoYear,
...     ExtractYear,
... )
>>> start_2015 = datetime(2015, 6, 15, 23, 30, 1, tzinfo=timezone.utc)

```

(continues on next page)

(continued from previous page)

```

>>> end_2015 = datetime(2015, 6, 16, 13, 11, 27, tzinfo=timezone.utc)
>>> Experiment.objects.create(
...     start_datetime=start_2015,
...     start_date=start_2015.date(),
...     end_datetime=end_2015,
...     end_date=end_2015.date(),
... )
>>> Experiment.objects.annotate(
...     year=ExtractYear("start_datetime"),
...     isoyear=ExtractIsoYear("start_datetime"),
...     quarter=ExtractQuarter("start_datetime"),
...     month=ExtractMonth("start_datetime"),
...     week=ExtractWeek("start_datetime"),
...     day=ExtractDay("start_datetime"),
...     weekday=ExtractWeekDay("start_datetime"),
...     isoweekday=ExtractIsoWeekDay("start_datetime"),
...     hour=ExtractHour("start_datetime"),
...     minute=ExtractMinute("start_datetime"),
...     second=ExtractSecond("start_datetime"),
... ).values(
...     "year",
...     "isoyear",
...     "month",
...     "week",
...     "day",
...     "weekday",
...     "isoweekday",
...     "hour",
...     "minute",
...     "second",
... ).get(
...     end_datetime__year=ExtractYear("start_datetime")
... )
{'year': 2015, 'isoyear': 2015, 'quarter': 2, 'month': 6, 'week': 25,
 'day': 15, 'weekday': 2, 'isoweekday': 1, 'hour': 23, 'minute': 30,
 'second': 1}

```

When `USE_TZ` is `True` then datetimes are stored in the database in UTC. If a different timezone is active in Django, the datetime is converted to that timezone before the value is extracted. The example below converts to the Melbourne timezone (UTC +10:00), which changes the day, weekday, and hour values that are returned:

```

>>> from django.utils import timezone

```

(continues on next page)

(continued from previous page)

```
>>> import zoneinfo
>>> melb = zoneinfo.ZoneInfo("Australia/Melbourne") # UTC+10:00
>>> with timezone.override(melb):
...     Experiment.objects.annotate(
...         day=ExtractDay("start_datetime"),
...         weekday=ExtractWeekDay("start_datetime"),
...         isoweekday=ExtractIsoWeekDay("start_datetime"),
...         hour=ExtractHour("start_datetime"),
...     ).values("day", "weekday", "isoweekday", "hour").get(
...         end_datetime__year=ExtractYear("start_datetime"),
...     )
...
{'day': 16, 'weekday': 3, 'isoweekday': 2, 'hour': 9}
```

Explicitly passing the timezone to the `Extract` function behaves in the same way, and takes priority over an active timezone:

```
>>> import zoneinfo
>>> melb = zoneinfo.ZoneInfo("Australia/Melbourne")
>>> Experiment.objects.annotate(
...     day=ExtractDay("start_datetime", tzinfo=melb),
...     weekday=ExtractWeekDay("start_datetime", tzinfo=melb),
...     isoweekday=ExtractIsoWeekDay("start_datetime", tzinfo=melb),
...     hour=ExtractHour("start_datetime", tzinfo=melb),
... ).values("day", "weekday", "isoweekday", "hour").get(
...     end_datetime__year=ExtractYear("start_datetime"),
... )
{'day': 16, 'weekday': 3, 'isoweekday': 2, 'hour': 9}
```

Now

```
class Now
```

Returns the database server's current date and time when the query is executed, typically using the SQL `CURRENT_TIMESTAMP`.

Usage example:

```
>>> from django.db.models.functions import Now
>>> Article.objects.filter(published__lte=Now())
<QuerySet [Article: How to Django]>
```

PostgreSQL considerations

On PostgreSQL, the SQL `CURRENT_TIMESTAMP` returns the time that the current transaction started. Therefore for cross-database compatibility, `Now()` uses `STATEMENT_TIMESTAMP` instead. If you need the transaction timestamp, use `django.contrib.postgres.functions.TransactionNow`.

Support for microsecond precision on MySQL and millisecond precision on SQLite were added.

Trunc

```
class Trunc(expression, kind, output_field=None, tzinfo=None, is_dst=None, **extra)
```

Truncates a date up to a significant component.

When you only care if something happened in a particular year, hour, or day, but not the exact second, then `Trunc` (and its subclasses) can be useful to filter or aggregate your data. For example, you can use `Trunc` to calculate the number of sales per day.

`Trunc` takes a single `expression`, representing a `DateField`, `TimeField`, or `DateTimeField`, a `kind` representing a date or time part, and an `output_field` that's either `DateTimeField()`, `TimeField()`, or `DateField()`. It returns a datetime, date, or time depending on `output_field`, with fields up to `kind` set to their minimum value. If `output_field` is omitted, it will default to the `output_field` of `expression`. A `tzinfo` subclass, usually provided by `zoneinfo`, can be passed to truncate a value in a specific timezone.

Deprecated since version 4.0: The `is_dst` parameter indicates whether or not `pytz` should interpret non-existent and ambiguous datetimes in daylight saving time. By default (when `is_dst=None`), `pytz` raises an exception for such datetimes.

The `is_dst` parameter is deprecated and will be removed in Django 5.0.

Given the datetime `2015-06-15 14:30:50.000321+00:00`, the built-in `kinds` return:

- “year” : 2015-01-01 00:00:00+00:00
- “quarter” : 2015-04-01 00:00:00+00:00
- “month” : 2015-06-01 00:00:00+00:00
- “week” : 2015-06-15 00:00:00+00:00
- “day” : 2015-06-15 00:00:00+00:00
- “hour” : 2015-06-15 14:00:00+00:00
- “minute” : 2015-06-15 14:30:00+00:00
- “second” : 2015-06-15 14:30:50+00:00

If a different timezone like `Australia/Melbourne` is active in Django, then the datetime is converted to the new timezone before the value is truncated. The timezone offset for Melbourne in the example date above is `+10:00`. The values returned when this timezone is active will be:

- “year” : 2015-01-01 00:00:00+11:00

- “quarter” : 2015-04-01 00:00:00+10:00
- “month” : 2015-06-01 00:00:00+10:00
- “week” : 2015-06-16 00:00:00+10:00
- “day” : 2015-06-16 00:00:00+10:00
- “hour” : 2015-06-16 00:00:00+10:00
- “minute” : 2015-06-16 00:30:00+10:00
- “second” : 2015-06-16 00:30:50+10:00

The year has an offset of +11:00 because the result transitioned into daylight saving time.

Each `kind` above has a corresponding `Trunc` subclass (listed below) that should typically be used instead of the more verbose equivalent, e.g. use `TruncYear(...)` rather than `Trunc(..., kind='year')`.

The subclasses are all defined as transforms, but they aren't registered with any fields, because the lookup names are already reserved by the `Extract` subclasses.

Usage example:

```
>>> from datetime import datetime
>>> from django.db.models import Count, DateTimeField
>>> from django.db.models.functions import Trunc
>>> Experiment.objects.create(start_datetime=datetime(2015, 6, 15, 14, 30, 50, 321))
>>> Experiment.objects.create(start_datetime=datetime(2015, 6, 15, 14, 40, 2, 123))
>>> Experiment.objects.create(start_datetime=datetime(2015, 12, 25, 10, 5, 27, 999))
>>> experiments_per_day = (
...     Experiment.objects.annotate(
...         start_day=Trunc("start_datetime", "day", output_field=DateTimeField())
...     )
...     .values("start_day")
...     .annotate(experiments=Count("id"))
... )
>>> for exp in experiments_per_day:
...     print(exp["start_day"], exp["experiments"])
...
2015-06-15 00:00:00 2
2015-12-25 00:00:00 1
>>> experiments = Experiment.objects.annotate(
...     start_day=Trunc("start_datetime", "day", output_field=DateTimeField())
... ).filter(start_day=datetime(2015, 6, 15))
>>> for exp in experiments:
...     print(exp.start_datetime)
...
2015-06-15 14:30:50.000321
2015-06-15 14:40:02.000123
```

DateField truncation

```
class TruncYear(expression, output_field=None, tzinfo=None, is_dst=None, **extra)
```

```
    kind = 'year'
```

```
class TruncMonth(expression, output_field=None, tzinfo=None, is_dst=None, **extra)
```

```
    kind = 'month'
```

```
class TruncWeek(expression, output_field=None, tzinfo=None, is_dst=None, **extra)
```

Truncates to midnight on the Monday of the week.

```
    kind = 'week'
```

```
class TruncQuarter(expression, output_field=None, tzinfo=None, is_dst=None, **extra)
```

```
    kind = 'quarter'
```

Deprecated since version 4.0: The `is_dst` parameter is deprecated and will be removed in Django 5.0.

These are logically equivalent to `Trunc('date_field', kind)`. They truncate all parts of the date up to `kind` which allows grouping or filtering dates with less precision. `expression` can have an `output_field` of either `DateField` or `DateTimeField`.

Since `DateFields` don't have a time component, only `Trunc` subclasses that deal with date-parts can be used with `DateField`:

```
>>> from datetime import datetime, timezone
>>> from django.db.models import Count
>>> from django.db.models.functions import TruncMonth, TruncYear
>>> start1 = datetime(2014, 6, 15, 14, 30, 50, 321, tzinfo=timezone.utc)
>>> start2 = datetime(2015, 6, 15, 14, 40, 2, 123, tzinfo=timezone.utc)
>>> start3 = datetime(2015, 12, 31, 17, 5, 27, 999, tzinfo=timezone.utc)
>>> Experiment.objects.create(start_datetime=start1, start_date=start1.date())
>>> Experiment.objects.create(start_datetime=start2, start_date=start2.date())
>>> Experiment.objects.create(start_datetime=start3, start_date=start3.date())
>>> experiments_per_year = (
...     Experiment.objects.annotate(year=TruncYear("start_date"))
...     .values("year")
...     .annotate(experiments=Count("id"))
... )
>>> for exp in experiments_per_year:
...     print(exp["year"], exp["experiments"])
...
2014-01-01 1
2015-01-01 2
```

(continues on next page)

(continued from previous page)

```

>>> import zoneinfo
>>> melb = zoneinfo.ZoneInfo("Australia/Melbourne")
>>> experiments_per_month = (
...     Experiment.objects.annotate(month=TruncMonth("start_datetime", tzinfo=melb))
...     .values("month")
...     .annotate(experiments=Count("id"))
... )
>>> for exp in experiments_per_month:
...     print(exp["month"], exp["experiments"])
...
2015-06-01 00:00:00+10:00 1
2016-01-01 00:00:00+11:00 1
2014-06-01 00:00:00+10:00 1

```

DateTimeField truncation

```
class TruncDate(expression, tzinfo=None, **extra)
```

```
    lookup_name = 'date'
```

```
    output_field = DateField()
```

TruncDate casts expression to a date rather than using the built-in SQL truncate function. It's also registered as a transform on DateTimeField as `__date`.

```
class TruncTime(expression, tzinfo=None, **extra)
```

```
    lookup_name = 'time'
```

```
    output_field = TimeField()
```

TruncTime casts expression to a time rather than using the built-in SQL truncate function. It's also registered as a transform on DateTimeField as `__time`.

```
class TruncDay(expression, output_field=None, tzinfo=None, is_dst=None, **extra)
```

```
    kind = 'day'
```

```
class TruncHour(expression, output_field=None, tzinfo=None, is_dst=None, **extra)
```

```
    kind = 'hour'
```

```
class TruncMinute(expression, output_field=None, tzinfo=None, is_dst=None, **extra)
```

```
    kind = 'minute'
```

```
class TruncSecond(expression, output_field=None, tzinfo=None, is_dst=None, **extra)

    kind = 'second'
```

Deprecated since version 4.0: The `is_dst` parameter is deprecated and will be removed in Django 5.0.

These are logically equivalent to `Trunc('datetime_field', kind)`. They truncate all parts of the date up to `kind` and allow grouping or filtering datetimes with less precision. `expression` must have an `output_field` of `DateTimeField`.

Usage example:

```
>>> from datetime import date, datetime, timezone
>>> from django.db.models import Count
>>> from django.db.models.functions import (
...     TruncDate,
...     TruncDay,
...     TruncHour,
...     TruncMinute,
...     TruncSecond,
... )
>>> import zoneinfo
>>> start1 = datetime(2014, 6, 15, 14, 30, 50, 321, tzinfo=timezone.utc)
>>> Experiment.objects.create(start_datetime=start1, start_date=start1.date())
>>> melb = zoneinfo.ZoneInfo("Australia/Melbourne")
>>> Experiment.objects.annotate(
...     date=TruncDate("start_datetime"),
...     day=TruncDay("start_datetime", tzinfo=melb),
...     hour=TruncHour("start_datetime", tzinfo=melb),
...     minute=TruncMinute("start_datetime"),
...     second=TruncSecond("start_datetime"),
... ).values("date", "day", "hour", "minute", "second").get()
{'date': datetime.date(2014, 6, 15),
 'day': datetime.datetime(2014, 6, 16, 0, 0, tzinfo=zoneinfo.ZoneInfo('Australia/Melbourne')),
 'hour': datetime.datetime(2014, 6, 16, 0, 0, tzinfo=zoneinfo.ZoneInfo('Australia/Melbourne')),
 'minute': 'minute': datetime.datetime(2014, 6, 15, 14, 30, tzinfo=timezone.utc),
 'second': datetime.datetime(2014, 6, 15, 14, 30, 50, tzinfo=timezone.utc)
}
```

TimeField truncation

```
class TruncHour(expression, output_field=None, tzinfo=None, is_dst=None, **extra)
```

```
    kind = 'hour'
```

```
class TruncMinute(expression, output_field=None, tzinfo=None, is_dst=None, **extra)
```

```
    kind = 'minute'
```

```
class TruncSecond(expression, output_field=None, tzinfo=None, is_dst=None, **extra)
```

```
    kind = 'second'
```

Deprecated since version 4.0: The `is_dst` parameter is deprecated and will be removed in Django 5.0.

These are logically equivalent to `Trunc('time_field', kind)`. They truncate all parts of the time up to `kind` which allows grouping or filtering times with less precision. `expression` can have an `output_field` of either `TimeField` or `DateTimeField`.

Since `TimeFields` don't have a date component, only `Trunc` subclasses that deal with time-parts can be used with `TimeField`:

```
>>> from datetime import datetime, timezone
>>> from django.db.models import Count, TimeField
>>> from django.db.models.functions import TruncHour
>>> start1 = datetime(2014, 6, 15, 14, 30, 50, 321, tzinfo=timezone.utc)
>>> start2 = datetime(2014, 6, 15, 14, 40, 2, 123, tzinfo=timezone.utc)
>>> start3 = datetime(2015, 12, 31, 17, 5, 27, 999, tzinfo=timezone.utc)
>>> Experiment.objects.create(start_datetime=start1, start_time=start1.time())
>>> Experiment.objects.create(start_datetime=start2, start_time=start2.time())
>>> Experiment.objects.create(start_datetime=start3, start_time=start3.time())
>>> experiments_per_hour = (
...     Experiment.objects.annotate(
...         hour=TruncHour("start_datetime", output_field=TimeField()),
...     )
...     .values("hour")
...     .annotate(experiments=Count("id"))
... )
>>> for exp in experiments_per_hour:
...     print(exp["hour"], exp["experiments"])
...
14:00:00 2
17:00:00 1

>>> import zoneinfo
>>> melb = zoneinfo.ZoneInfo("Australia/Melbourne")
```

(continues on next page)

(continued from previous page)

```
>>> experiments_per_hour = (
...     Experiment.objects.annotate(
...         hour=TruncHour("start_datetime", tzinfo=melb),
...     )
...     .values("hour")
...     .annotate(experiments=Count("id"))
... )
>>> for exp in experiments_per_hour:
...     print(exp["hour"], exp["experiments"])
...
2014-06-16 00:00:00+10:00 2
2016-01-01 04:00:00+11:00 1
```

Math Functions

We'll be using the following model in math function examples:

```
class Vector(models.Model):
    x = models.FloatField()
    y = models.FloatField()
```

Abs

```
class Abs(expression, **extra)
```

Returns the absolute value of a numeric field or expression.

Usage example:

```
>>> from django.db.models.functions import Abs
>>> Vector.objects.create(x=-0.5, y=1.1)
>>> vector = Vector.objects.annotate(x_abs=Abs("x"), y_abs=Abs("y")).get()
>>> vector.x_abs, vector.y_abs
(0.5, 1.1)
```

It can also be registered as a transform. For example:

```
>>> from django.db.models import FloatField
>>> from django.db.models.functions import Abs
>>> FloatField.register_lookup(Abs)
>>> # Get vectors inside the unit cube
>>> vectors = Vector.objects.filter(x__abs__lt=1, y__abs__lt=1)
```

ACos

```
class ACos(expression, **extra)
```

Returns the arccosine of a numeric field or expression. The expression value must be within the range -1 to 1.

Usage example:

```
>>> from django.db.models.functions import ACos
>>> Vector.objects.create(x=0.5, y=-0.9)
>>> vector = Vector.objects.annotate(x_acos=ACos("x"), y_acos=ACos("y")).get()
>>> vector.x_acos, vector.y_acos
(1.0471975511965979, 2.6905658417935308)
```

It can also be registered as a transform. For example:

```
>>> from django.db.models import FloatField
>>> from django.db.models.functions import ACos
>>> FloatField.register_lookup(ACos)
>>> # Get vectors whose arccosine is less than 1
>>> vectors = Vector.objects.filter(x__acos__lt=1, y__acos__lt=1)
```

ASin

```
class ASin(expression, **extra)
```

Returns the arcsine of a numeric field or expression. The expression value must be in the range -1 to 1.

Usage example:

```
>>> from django.db.models.functions import ASin
>>> Vector.objects.create(x=0, y=1)
>>> vector = Vector.objects.annotate(x_asin=ASin("x"), y_asin=ASin("y")).get()
>>> vector.x_asin, vector.y_asin
(0.0, 1.5707963267948966)
```

It can also be registered as a transform. For example:

```
>>> from django.db.models import FloatField
>>> from django.db.models.functions import ASin
>>> FloatField.register_lookup(ASin)
>>> # Get vectors whose arcsine is less than 1
>>> vectors = Vector.objects.filter(x__asin__lt=1, y__asin__lt=1)
```

ATan

```
class ATan(expression, **extra)
```

Returns the arctangent of a numeric field or expression.

Usage example:

```
>>> from django.db.models.functions import ATan
>>> Vector.objects.create(x=3.12, y=6.987)
>>> vector = Vector.objects.annotate(x_atan=ATan("x"), y_atan=ATan("y")).get()
>>> vector.x_atan, vector.y_atan
(1.2606282660069106, 1.428638798133829)
```

It can also be registered as a transform. For example:

```
>>> from django.db.models import FloatField
>>> from django.db.models.functions import ATan
>>> FloatField.register_lookup(ATan)
>>> # Get vectors whose arctangent is less than 2
>>> vectors = Vector.objects.filter(x__atan__lt=2, y__atan__lt=2)
```

ATan2

```
class ATan2(expression1, expression2, **extra)
```

Returns the arctangent of $\text{expression1} / \text{expression2}$.

Usage example:

```
>>> from django.db.models.functions import ATan2
>>> Vector.objects.create(x=2.5, y=1.9)
>>> vector = Vector.objects.annotate(atan2=ATan2("x", "y")).get()
>>> vector.atan2
0.9209258773829491
```

Ceil

```
class Ceil(expression, **extra)
```

Returns the smallest integer greater than or equal to a numeric field or expression.

Usage example:

```
>>> from django.db.models.functions import Ceil
>>> Vector.objects.create(x=3.12, y=7.0)
>>> vector = Vector.objects.annotate(x_ceil=Ceil("x"), y_ceil=Ceil("y")).get()
>>> vector.x_ceil, vector.y_ceil
(4.0, 7.0)
```

It can also be registered as a transform. For example:

```
>>> from django.db.models import FloatField
>>> from django.db.models.functions import Ceil
>>> FloatField.register_lookup(Ceil)
>>> # Get vectors whose ceil is less than 10
>>> vectors = Vector.objects.filter(x__ceil__lt=10, y__ceil__lt=10)
```

Cos

```
class Cos(expression, **extra)
```

Returns the cosine of a numeric field or expression.

Usage example:

```
>>> from django.db.models.functions import Cos
>>> Vector.objects.create(x=-8.0, y=3.1415926)
>>> vector = Vector.objects.annotate(x_cos=Cos("x"), y_cos=Cos("y")).get()
>>> vector.x_cos, vector.y_cos
(-0.14550003380861354, -0.9999999999999986)
```

It can also be registered as a transform. For example:

```
>>> from django.db.models import FloatField
>>> from django.db.models.functions import Cos
>>> FloatField.register_lookup(Cos)
>>> # Get vectors whose cosine is less than 0.5
>>> vectors = Vector.objects.filter(x__cos__lt=0.5, y__cos__lt=0.5)
```

Cot

```
class Cot(expression, **extra)
```

Returns the cotangent of a numeric field or expression.

Usage example:

```
>>> from django.db.models.functions import Cot
>>> Vector.objects.create(x=12.0, y=1.0)
>>> vector = Vector.objects.annotate(x_cot=Cot("x"), y_cot=Cot("y")).get()
>>> vector.x_cot, vector.y_cot
(-1.5726734063976826, 0.642092615934331)
```

It can also be registered as a transform. For example:

```
>>> from django.db.models import FloatField
>>> from django.db.models.functions import Cot
>>> FloatField.register_lookup(Cot)
>>> # Get vectors whose cotangent is less than 1
>>> vectors = Vector.objects.filter(x__cot__lt=1, y__cot__lt=1)
```

Degrees

```
class Degrees(expression, **extra)
```

Converts a numeric field or expression from radians to degrees.

Usage example:

```
>>> from django.db.models.functions import Degrees
>>> Vector.objects.create(x=-1.57, y=3.14)
>>> vector = Vector.objects.annotate(x_d=Degrees("x"), y_d=Degrees("y")).get()
>>> vector.x_d, vector.y_d
(-89.95437383553924, 179.9087476710785)
```

It can also be registered as a transform. For example:

```
>>> from django.db.models import FloatField
>>> from django.db.models.functions import Degrees
>>> FloatField.register_lookup(Degrees)
>>> # Get vectors whose degrees are less than 360
>>> vectors = Vector.objects.filter(x__degrees__lt=360, y__degrees__lt=360)
```

Exp

```
class Exp(expression, **extra)
```

Returns the value of e (the natural logarithm base) raised to the power of a numeric field or expression.

Usage example:

```
>>> from django.db.models.functions import Exp
>>> Vector.objects.create(x=5.4, y=-2.0)
>>> vector = Vector.objects.annotate(x_exp=Exp("x"), y_exp=Exp("y")).get()
>>> vector.x_exp, vector.y_exp
(221.40641620418717, 0.1353352832366127)
```

It can also be registered as a transform. For example:

```
>>> from django.db.models import FloatField
>>> from django.db.models.functions import Exp
>>> FloatField.register_lookup(Exp)
>>> # Get vectors whose exp() is greater than 10
>>> vectors = Vector.objects.filter(x__exp__gt=10, y__exp__gt=10)
```

Floor

```
class Floor(expression, **extra)
```

Returns the largest integer value not greater than a numeric field or expression.

Usage example:

```
>>> from django.db.models.functions import Floor
>>> Vector.objects.create(x=5.4, y=-2.3)
>>> vector = Vector.objects.annotate(x_floor=Floor("x"), y_floor=Floor("y")).get()
>>> vector.x_floor, vector.y_floor
(5.0, -3.0)
```

It can also be registered as a transform. For example:

```
>>> from django.db.models import FloatField
>>> from django.db.models.functions import Floor
>>> FloatField.register_lookup(Floor)
>>> # Get vectors whose floor() is greater than 10
>>> vectors = Vector.objects.filter(x__floor__gt=10, y__floor__gt=10)
```

Ln

```
class Ln(expression, **extra)
```

Returns the natural logarithm a numeric field or expression.

Usage example:

```
>>> from django.db.models.functions import Ln
>>> Vector.objects.create(x=5.4, y=233.0)
>>> vector = Vector.objects.annotate(x_ln=Ln("x"), y_ln=Ln("y")).get()
>>> vector.x_ln, vector.y_ln
(1.6863989535702288, 5.4510384535657)
```

It can also be registered as a transform. For example:

```
>>> from django.db.models import FloatField
>>> from django.db.models.functions import Ln
>>> FloatField.register_lookup(Ln)
>>> # Get vectors whose value greater than e
>>> vectors = Vector.objects.filter(x__ln__gt=1, y__ln__gt=1)
```

Log

```
class Log(expression1, expression2, **extra)
```

Accepts two numeric fields or expressions and returns the logarithm of the second to base of the first.

Usage example:

```
>>> from django.db.models.functions import Log
>>> Vector.objects.create(x=2.0, y=4.0)
>>> vector = Vector.objects.annotate(log=Log("x", "y")).get()
>>> vector.log
2.0
```

Mod

```
class Mod(expression1, expression2, **extra)
```

Accepts two numeric fields or expressions and returns the remainder of the first divided by the second (modulo operation).

Usage example:

```
>>> from django.db.models.functions import Mod
>>> Vector.objects.create(x=5.4, y=2.3)
>>> vector = Vector.objects.annotate(mod=Mod("x", "y")).get()
>>> vector.mod
0.8
```

Pi

```
class Pi(**extra)
```

Returns the value of the mathematical constant π .

Power

```
class Power(expression1, expression2, **extra)
```

Accepts two numeric fields or expressions and returns the value of the first raised to the power of the second.

Usage example:

```
>>> from django.db.models.functions import Power
>>> Vector.objects.create(x=2, y=-2)
>>> vector = Vector.objects.annotate(power=Power("x", "y")).get()
>>> vector.power
0.25
```

Radians

```
class Radians(expression, **extra)
```

Converts a numeric field or expression from degrees to radians.

Usage example:

```
>>> from django.db.models.functions import Radians
>>> Vector.objects.create(x=-90, y=180)
>>> vector = Vector.objects.annotate(x_r=Radians("x"), y_r=Radians("y")).get()
>>> vector.x_r, vector.y_r
(-1.5707963267948966, 3.141592653589793)
```

It can also be registered as a transform. For example:

```
>>> from django.db.models import FloatField
>>> from django.db.models.functions import Radians
>>> FloatField.register_lookup(Radians)
>>> # Get vectors whose radians are less than 1
>>> vectors = Vector.objects.filter(x__radians__lt=1, y__radians__lt=1)
```

Random

```
class Random(**extra)
```

Returns a random value in the range $0.0 \leq x < 1.0$.

Round

```
class Round(expression, precision=0, **extra)
```

Rounds a numeric field or expression to `precision` (must be an integer) decimal places. By default, it rounds to the nearest integer. Whether half values are rounded up or down depends on the database.

Usage example:

```
>>> from django.db.models.functions import Round
>>> Vector.objects.create(x=5.4, y=-2.37)
>>> vector = Vector.objects.annotate(x_r=Round("x"), y_r=Round("y", precision=1)).get()
>>> vector.x_r, vector.y_r
(5.0, -2.4)
```

It can also be registered as a transform. For example:

```
>>> from django.db.models import FloatField
>>> from django.db.models.functions import Round
>>> FloatField.register_lookup(Round)
>>> # Get vectors whose round() is less than 20
>>> vectors = Vector.objects.filter(x__round__lt=20, y__round__lt=20)
```

Sign

```
class Sign(expression, **extra)
```

Returns the sign (-1, 0, 1) of a numeric field or expression.

Usage example:

```
>>> from django.db.models.functions import Sign
>>> Vector.objects.create(x=5.4, y=-2.3)
>>> vector = Vector.objects.annotate(x_sign=Sign("x"), y_sign=Sign("y")).get()
>>> vector.x_sign, vector.y_sign
(1, -1)
```

It can also be registered as a transform. For example:

```
>>> from django.db.models import FloatField
>>> from django.db.models.functions import Sign
>>> FloatField.register_lookup(Sign)
>>> # Get vectors whose signs of components are less than 0.
>>> vectors = Vector.objects.filter(x__sign__lt=0, y__sign__lt=0)
```

Sin

```
class Sin(expression, **extra)
```

Returns the sine of a numeric field or expression.

Usage example:

```
>>> from django.db.models.functions import Sin
>>> Vector.objects.create(x=5.4, y=-2.3)
>>> vector = Vector.objects.annotate(x_sin=Sin("x"), y_sin=Sin("y")).get()
>>> vector.x_sin, vector.y_sin
(-0.7727644875559871, -0.7457052121767203)
```

It can also be registered as a transform. For example:

```
>>> from django.db.models import FloatField
>>> from django.db.models.functions import Sin
>>> FloatField.register_lookup(Sin)
>>> # Get vectors whose sin() is less than 0
>>> vectors = Vector.objects.filter(x__sin__lt=0, y__sin__lt=0)
```

Sqrt

```
class Sqrt(expression, **extra)
```

Returns the square root of a nonnegative numeric field or expression.

Usage example:

```
>>> from django.db.models.functions import Sqrt
>>> Vector.objects.create(x=4.0, y=12.0)
>>> vector = Vector.objects.annotate(x_sqrt=Sqrt("x"), y_sqrt=Sqrt("y")).get()
>>> vector.x_sqrt, vector.y_sqrt
(2.0, 3.46410)
```

It can also be registered as a transform. For example:

```
>>> from django.db.models import FloatField
>>> from django.db.models.functions import Sqrt
>>> FloatField.register_lookup(Sqrt)
>>> # Get vectors whose sqrt() is less than 5
>>> vectors = Vector.objects.filter(x__sqrt__lt=5, y__sqrt__lt=5)
```

Tan

```
class Tan(expression, **extra)
```

Returns the tangent of a numeric field or expression.

Usage example:

```
>>> from django.db.models.functions import Tan
>>> Vector.objects.create(x=0, y=12)
>>> vector = Vector.objects.annotate(x_tan=Tan("x"), y_tan=Tan("y")).get()
>>> vector.x_tan, vector.y_tan
(0.0, -0.6358599286615808)
```

It can also be registered as a transform. For example:

```
>>> from django.db.models import FloatField
>>> from django.db.models.functions import Tan
>>> FloatField.register_lookup(Tan)
>>> # Get vectors whose tangent is less than 0
>>> vectors = Vector.objects.filter(x__tan__lt=0, y__tan__lt=0)
```

Text functions

Chr

```
class Chr(expression, **extra)
```

Accepts a numeric field or expression and returns the text representation of the expression as a single character. It works the same as Python's `chr()` function.

Like *Length*, it can be registered as a transform on `IntegerField`. The default lookup name is `chr`.

Usage example:

```
>>> from django.db.models.functions import Chr
>>> Author.objects.create(name="Margaret Smith")
>>> author = Author.objects.filter(name__startswith=Chr(ord("M"))).get()
>>> print(author.name)
Margaret Smith
```

Concat

```
class Concat(*expressions, **extra)
```

Accepts a list of at least two text fields or expressions and returns the concatenated text. Each argument must be of a text or char type. If you want to concatenate a `TextField()` with a `CharField()`, then be sure to tell Django that the `output_field` should be a `TextField()`. Specifying an `output_field` is also required when concatenating a `Value` as in the example below.

This function will never have a null result. On backends where a null argument results in the entire expression being null, Django will ensure that each null part is converted to an empty string first.

Usage example:

```
>>> # Get the display name as "name (goes_by)"
>>> from django.db.models import CharField, Value as V
>>> from django.db.models.functions import Concat
>>> Author.objects.create(name="Margaret Smith", goes_by="Maggie")
>>> author = Author.objects.annotate(
...     screen_name=Concat("name", V(" ("), "goes_by", V(")"), output_field=CharField())
... ).get()
>>> print(author.screen_name)
Margaret Smith (Maggie)
```

Left

```
class Left(expression, length, **extra)
```

Returns the first `length` characters of the given text field or expression.

Usage example:

```
>>> from django.db.models.functions import Left
>>> Author.objects.create(name="Margaret Smith")
>>> author = Author.objects.annotate(first_initial=Left("name", 1)).get()
>>> print(author.first_initial)
```

M

Length

```
class Length(expression, **extra)
```

Accepts a single text field or expression and returns the number of characters the value has. If the expression is null, then the length will also be null.

Usage example:

```
>>> # Get the length of the name and goes_by fields
>>> from django.db.models.functions import Length
>>> Author.objects.create(name="Margaret Smith")
>>> author = Author.objects.annotate(
...     name_length=Length("name"), goes_by_length=Length("goes_by")
... ).get()
>>> print(author.name_length, author.goes_by_length)
(14, None)
```

It can also be registered as a transform. For example:

```
>>> from django.db.models import CharField
>>> from django.db.models.functions import Length
>>> CharField.register_lookup(Length)
>>> # Get authors whose name is longer than 7 characters
>>> authors = Author.objects.filter(name__length__gt=7)
```

Lower

```
class Lower(expression, **extra)
```

Accepts a single text field or expression and returns the lowercase representation.

It can also be registered as a transform as described in [Length](#).

Usage example:

```
>>> from django.db.models.functions import Lower
>>> Author.objects.create(name="Margaret Smith")
>>> author = Author.objects.annotate(name_lower=Lower("name")).get()
>>> print(author.name_lower)
margaret smith
```

LPad

```
class LPad(expression, length, fill_text=Value(' '), **extra)
```

Returns the value of the given text field or expression padded on the left side with `fill_text` so that the resulting value is `length` characters long. The default `fill_text` is a space.

Usage example:

```
>>> from django.db.models import Value
>>> from django.db.models.functions import LPad
>>> Author.objects.create(name="John", alias="j")
>>> Author.objects.update(name=LPad("name", 8, Value("abc")))
1
>>> print(Author.objects.get(alias="j").name)
abcaJohn
```

LTrim

```
class LTrim(expression, **extra)
```

Similar to [Trim](#), but removes only leading spaces.

MD5

```
class MD5(expression, **extra)
```

Accepts a single text field or expression and returns the MD5 hash of the string.

It can also be registered as a transform as described in [Length](#).

Usage example:

```
>>> from django.db.models.functions import MD5
>>> Author.objects.create(name="Margaret Smith")
>>> author = Author.objects.annotate(name_md5=MD5("name")).get()
>>> print(author.name_md5)
749fb689816b2db85f5b169c2055b247
```

Ord

```
class Ord(expression, **extra)
```

Accepts a single text field or expression and returns the Unicode code point value for the first character of that expression. It works similar to Python's `ord()` function, but an exception isn't raised if the expression is more than one character long.

It can also be registered as a transform as described in [Length](#). The default lookup name is `ord`.

Usage example:

```
>>> from django.db.models.functions import Ord
>>> Author.objects.create(name="Margaret Smith")
>>> author = Author.objects.annotate(name_code_point=Ord("name")).get()
>>> print(author.name_code_point)
77
```

Repeat

```
class Repeat(expression, number, **extra)
```

Returns the value of the given text field or expression repeated `number` times.

Usage example:

```
>>> from django.db.models.functions import Repeat
>>> Author.objects.create(name="John", alias="j")
>>> Author.objects.update(name=Repeat("name", 3))
```

(continues on next page)

(continued from previous page)

```
1
>>> print(Author.objects.get(alias="j").name)
JohnJohnJohn
```

Replace

```
class Replace(expression, text, replacement=Value(""), **extra)
```

Replaces all occurrences of `text` with `replacement` in `expression`. The default replacement text is the empty string. The arguments to the function are case-sensitive.

Usage example:

```
>>> from django.db.models import Value
>>> from django.db.models.functions import Replace
>>> Author.objects.create(name="Margaret Johnson")
>>> Author.objects.create(name="Margaret Smith")
>>> Author.objects.update(name=Replace("name", Value("Margaret"), Value("Margareth")))
2
>>> Author.objects.values("name")
<QuerySet [{'name': 'Margareth Johnson'}, {'name': 'Margareth Smith'}]>
```

Reverse

```
class Reverse(expression, **extra)
```

Accepts a single text field or expression and returns the characters of that expression in reverse order.

It can also be registered as a transform as described in [Length](#). The default lookup name is `reverse`.

Usage example:

```
>>> from django.db.models.functions import Reverse
>>> Author.objects.create(name="Margaret Smith")
>>> author = Author.objects.annotate(backward=Reverse("name")).get()
>>> print(author.backward)
htimS teragraM
```

Right

```
class Right(expression, length, **extra)
```

Returns the last `length` characters of the given text field or expression.

Usage example:

```
>>> from django.db.models.functions import Right
>>> Author.objects.create(name="Margaret Smith")
>>> author = Author.objects.annotate(last_letter=Right("name", 1)).get()
>>> print(author.last_letter)
h
```

RPad

```
class RPad(expression, length, fill_text=Value(' '), **extra)
```

Similar to *LPad*, but pads on the right side.

RTrim

```
class RTrim(expression, **extra)
```

Similar to *Trim*, but removes only trailing spaces.

SHA1, SHA224, SHA256, SHA384, and SHA512

```
class SHA1(expression, **extra)
```

```
class SHA224(expression, **extra)
```

```
class SHA256(expression, **extra)
```

```
class SHA384(expression, **extra)
```

```
class SHA512(expression, **extra)
```

Accepts a single text field or expression and returns the particular hash of the string.

They can also be registered as transforms as described in *Length*.

Usage example:

```
>>> from django.db.models.functions import SHA1
>>> Author.objects.create(name="Margaret Smith")
>>> author = Author.objects.annotate(name_sha1=SHA1("name")).get()
>>> print(author.name_sha1)
b87efd8a6c991c390be5a68e8a7945a7851c7e5c
```

PostgreSQL

The `pgcrypto` extension must be installed. You can use the *CryptoExtension* migration operation to install it.

Oracle

Oracle doesn't support the SHA224 function.

StrIndex

```
class StrIndex(string, substring, **extra)
```

Returns a positive integer corresponding to the 1-indexed position of the first occurrence of `substring` inside `string`, or 0 if `substring` is not found.

Usage example:

```
>>> from django.db.models import Value as V
>>> from django.db.models.functions import StrIndex
>>> Author.objects.create(name="Margaret Smith")
>>> Author.objects.create(name="Smith, Margaret")
>>> Author.objects.create(name="Margaret Jackson")
>>> Author.objects.filter(name="Margaret Jackson").annotate(
...     smith_index=StrIndex("name", V("Smith"))
... ).get().smith_index
0
>>> authors = Author.objects.annotate(smith_index=StrIndex("name", V("Smith"))).filter(
...     smith_index__gt=0
... )
<QuerySet [<Author: Margaret Smith>, <Author: Smith, Margaret>]>
```

Warning: In MySQL, a database table's [collation](#) determines whether string comparisons (such as the `expression` and `substring` of this function) are case-sensitive. Comparisons are case-insensitive by default.

Substr

```
class Substr(expression, pos, length=None, **extra)
```

Returns a substring of length `length` from the field or expression starting at position `pos`. The position is 1-indexed, so the position must be greater than 0. If `length` is `None`, then the rest of the string will be returned.

Usage example:

```
>>> # Set the alias to the first 5 characters of the name as lowercase
>>> from django.db.models.functions import Lower, Substr
>>> Author.objects.create(name="Margaret Smith")
>>> Author.objects.update(alias=Lower(Substr("name", 1, 5)))
1
>>> print(Author.objects.get(name="Margaret Smith").alias)
marga
```

Trim

```
class Trim(expression, **extra)
```

Returns the value of the given text field or expression with leading and trailing spaces removed.

Usage example:

```
>>> from django.db.models.functions import Trim
>>> Author.objects.create(name=" John ", alias="j")
>>> Author.objects.update(name=Trim("name"))
1
>>> print(Author.objects.get(alias="j").name)
John
```

Upper

```
class Upper(expression, **extra)
```

Accepts a single text field or expression and returns the uppercase representation.

It can also be registered as a transform as described in [Length](#).

Usage example:

```
>>> from django.db.models.functions import Upper
>>> Author.objects.create(name="Margaret Smith")
>>> author = Author.objects.annotate(name_upper=Upper("name")).get()
>>> print(author.name_upper)
MARGARET SMITH
```

Window functions

There are a number of functions to use in a *Window* expression for computing the rank of elements or the *Ntile* of some rows.

CumeDist

```
class CumeDist(*expressions, **extra)
```

Calculates the cumulative distribution of a value within a window or partition. The cumulative distribution is defined as the number of rows preceding or peered with the current row divided by the total number of rows in the frame.

DenseRank

```
class DenseRank(*expressions, **extra)
```

Equivalent to [Rank](#) but does not have gaps.

FirstValue

```
class FirstValue(expression, **extra)
```

Returns the value evaluated at the row that's the first row of the window frame, or `None` if no such value exists.

Lag

```
class Lag(expression, offset=1, default=None, **extra)
```

Calculates the value offset by `offset`, and if no row exists there, returns `default`.

`default` must have the same type as the `expression`, however, this is only validated by the database and not in Python.

MariaDB and `default`

MariaDB *doesn't* support the `default` parameter.

LastValue

```
class LastValue(expression, **extra)
```

Comparable to *FirstValue*, it calculates the last value in a given frame clause.

Lead

```
class Lead(expression, offset=1, default=None, **extra)
```

Calculates the leading value in a given *frame*. Both `offset` and `default` are evaluated with respect to the current row.

`default` must have the same type as the `expression`, however, this is only validated by the database and not in Python.

MariaDB and `default`

MariaDB *doesn't* support the `default` parameter.

NthValue

```
class NthValue(expression, nth=1, **extra)
```

Computes the row relative to the offset `nth` (must be a positive value) within the window. Returns `None` if no row exists.

Some databases may handle a nonexistent `nth`-value differently. For example, Oracle returns an empty string rather than `None` for character-based expressions. Django *doesn't* do any conversions in these cases.

Ntile

```
class Ntile(num_buckets=1, **extra)
```

Calculates a partition for each of the rows in the frame clause, distributing numbers as evenly as possible between 1 and `num_buckets`. If the rows don't divide evenly into a number of buckets, one or more buckets will be represented more frequently.

PercentRank

```
class PercentRank(*expressions, **extra)
```

Computes the relative rank of the rows in the frame clause. This computation is equivalent to evaluating:

```
(rank - 1) / (total rows - 1)
```

The following table explains the calculation for the relative rank of a row:

Row #	Value	Rank	Calculation	Relative Rank
1	15	1	(1-1)/(7-1)	0.0000
2	20	2	(2-1)/(7-1)	0.1666
3	20	2	(2-1)/(7-1)	0.1666
4	20	2	(2-1)/(7-1)	0.1666
5	30	5	(5-1)/(7-1)	0.6666
6	30	5	(5-1)/(7-1)	0.6666
7	40	7	(7-1)/(7-1)	1.0000

Rank

```
class Rank(*expressions, **extra)
```

Comparable to `RowNumber`, this function ranks rows in the window. The computed rank contains gaps. Use *DenseRank* to compute rank without gaps.

`RowNumber`

```
class RowNumber(*expressions, **extra)
```

Computes the row number according to the ordering of either the frame clause or the ordering of the whole query if there is no partitioning of the [window frame](#).

6.17 Paginator

Django provides a few classes that help you manage paginated data –that is, data that’s split across several pages, with “Previous/Next” links. These classes live in [django/core/paginator.py](#).

For examples, see the [Pagination](#) topic guide.

6.17.1 Paginator class

```
class Paginator(object_list, per_page, orphans=0, allow_empty_first_page=True)
```

A paginator acts like a sequence of [Page](#) when using `len()` or iterating it directly.

`Paginator.object_list`

Required. A list, tuple, `QuerySet`, or other sliceable object with a `count()` or `__len__()` method. For consistent pagination, `QuerySets` should be ordered, e.g. with an [order_by\(\)](#) clause or with a default [ordering](#) on the model.

Performance issues paginating large `QuerySets`

If you’re using a `QuerySet` with a very large number of items, requesting high page numbers might be slow on some databases, because the resulting `LIMIT/OFFSET` query needs to count the number of `OFFSET` records which takes longer as the page number gets higher.

`Paginator.per_page`

Required. The maximum number of items to include on a page, not including orphans (see the [orphans](#) optional argument below).

`Paginator.orphans`

Optional. Use this when you don’t want to have a last page with very few items. If the last page would normally have a number of items less than or equal to `orphans`, then those items will be added to the previous page (which becomes the last page) instead of leaving the items on a page by themselves. For example, with 23 items, `per_page=10`, and `orphans=3`, there will be two pages; the first page with 10 items and the second (and last) page with 13 items. `orphans` defaults to zero, which means pages are never combined and the last page may have one item.

`Paginator.allow_empty_first_page`

Optional. Whether or not the first page is allowed to be empty. If `False` and `object_list` is empty, then an `EmptyPage` error will be raised.

Methods

`Paginator.get_page(number)`

Returns a [*Page*](#) object with the given 1-based index, while also handling out of range and invalid page numbers.

If the page isn't a number, it returns the first page. If the page number is negative or greater than the number of pages, it returns the last page.

Raises an [*EmptyPage*](#) exception only if you specify `Paginator(..., allow_empty_first_page=False)` and the `object_list` is empty.

`Paginator.page(number)`

Returns a [*Page*](#) object with the given 1-based index. Raises [*PageNotAnInteger*](#) if the `number` cannot be converted to an integer by calling `int()`. Raises [*EmptyPage*](#) if the given page number doesn't exist.

`Paginator.get_elided_page_range(number, *, on_each_side=3, on_ends=2)`

Returns a 1-based list of page numbers similar to [*Paginator.page_range*](#), but may add an ellipsis to either or both sides of the current page number when [*Paginator.num_pages*](#) is large.

The number of pages to include on each side of the current page number is determined by the `on_each_side` argument which defaults to 3.

The number of pages to include at the beginning and end of page range is determined by the `on_ends` argument which defaults to 2.

For example, with the default values for `on_each_side` and `on_ends`, if the current page is 10 and there are 50 pages, the page range will be `[1, 2, '...', 7, 8, 9, 10, 11, 12, 13, '...', 49, 50]`. This will result in pages 7, 8, and 9 to the left of and 11, 12, and 13 to the right of the current page as well as pages 1 and 2 at the start and 49 and 50 at the end.

Raises [*InvalidPage*](#) if the given page number doesn't exist.

Attributes

`Paginator.ELLIPSIS`

A translatable string used as a substitute for elided page numbers in the page range returned by [*get_elided_page_range\(\)*](#). Default is `'...'`.

`Paginator.count`

The total number of objects, across all pages.

Note: When determining the number of objects contained in `object_list`, `Paginator` will first try calling `object_list.count()`. If `object_list` has no `count()` method, then `Paginator` will fall back to using `len(object_list)`. This allows objects, such as `QuerySet`, to use a more efficient `count()` method when available.

`Paginator.num_pages`

The total number of pages.

`Paginator.page_range`

A 1-based range iterator of page numbers, e.g. yielding `[1, 2, 3, 4]`.

6.17.2 Page class

You usually won't construct `Page` objects by hand –you'll get them by iterating `Paginator`, or by using `Paginator.page()`.

class `Page(object_list, number, paginator)`

A page acts like a sequence of `Page.object_list` when using `len()` or iterating it directly.

Methods

`Page.has_next()`

Returns `True` if there's a next page.

`Page.has_previous()`

Returns `True` if there's a previous page.

`Page.has_other_pages()`

Returns `True` if there's a next or previous page.

`Page.next_page_number()`

Returns the next page number. Raises `InvalidPage` if next page doesn't exist.

`Page.previous_page_number()`

Returns the previous page number. Raises `InvalidPage` if previous page doesn't exist.

`Page.start_index()`

Returns the 1-based index of the first object on the page, relative to all of the objects in the paginator's list. For example, when paginating a list of 5 objects with 2 objects per page, the second page's `start_index()` would return 3.

`Page.end_index()`

Returns the 1-based index of the last object on the page, relative to all of the objects in the paginator's list. For example, when paginating a list of 5 objects with 2 objects per page, the second page's `end_index()` would return 4.

Attributes

`Page.object_list`

The list of objects on this page.

`Page.number`

The 1-based page number for this page.

`Page.paginator`

The associated *Paginator* object.

6.17.3 Exceptions

exception `InvalidPage`

A base class for exceptions raised when a paginator is passed an invalid page number.

The *Paginator*.`page()` method raises an exception if the requested page is invalid (i.e. not an integer) or contains no objects. Generally, it's enough to catch the `InvalidPage` exception, but if you'd like more granularity, you can catch either of the following exceptions:

exception `PageNotAnInteger`

Raised when `page()` is given a value that isn't an integer.

exception `EmptyPage`

Raised when `page()` is given a valid value but no objects exist on that page.

Both of the exceptions are subclasses of *InvalidPage*, so you can handle them both with `except InvalidPage`.

6.18 Request and response objects

6.18.1 Quick overview

Django uses request and response objects to pass state through the system.

When a page is requested, Django creates an *HttpRequest* object that contains metadata about the request. Then Django loads the appropriate view, passing the *HttpRequest* as the first argument to the view function. Each view is responsible for returning an *HttpResponse* object.

This document explains the APIs for *HttpRequest* and *HttpResponse* objects, which are defined in the *django.http* module.

6.18.2 HttpRequest objects

`class HttpRequest`

Attributes

All attributes should be considered read-only, unless stated otherwise.

`HttpRequest.scheme`

A string representing the scheme of the request (`http` or `https` usually).

`HttpRequest.body`

The raw HTTP request body as a bytestring. This is useful for processing data in different ways than conventional HTML forms: binary images, XML payload etc. For processing conventional form data, use *HttpRequest.POST*.

You can also read from an `HttpRequest` using a file-like interface with *HttpRequest.read()* or *HttpRequest.readline()*. Accessing the `body` attribute after reading the request with either of these I/O stream methods will produce a `RawPostDataException`.

`HttpRequest.path`

A string representing the full path to the requested page, not including the scheme, domain, or query string.

Example: `"/music/bands/the_beatles/"`

`HttpRequest.path_info`

Under some web server configurations, the portion of the URL after the host name is split up into a script prefix portion and a path info portion. The `path_info` attribute always contains the path info portion of the path, no matter what web server is being used. Using this instead of *path* can make your code easier to move between test and deployment servers.

For example, if the `WSGIScriptAlias` for your application is set to `"/minfo"`, then `path` might be `"/minfo/music/bands/the_beatles/"` and `path_info` would be `"/music/bands/the_beatles/"`.

`HttpRequest.method`

A string representing the HTTP method used in the request. This is guaranteed to be uppercase. For example:

```
if request.method == "GET":
    do_something()
```

(continues on next page)

(continued from previous page)

```
elif request.method == "POST":
    do_something_else()
```

`HttpRequest.encoding`

A string representing the current encoding used to decode form submission data (or `None`, which means the `DEFAULT_CHARSET` setting is used). You can write to this attribute to change the encoding used when accessing the form data. Any subsequent attribute accesses (such as reading from `GET` or `POST`) will use the new `encoding` value. Useful if you know the form data is not in the `DEFAULT_CHARSET` encoding.

`HttpRequest.content_type`

A string representing the MIME type of the request, parsed from the `CONTENT_TYPE` header.

`HttpRequest.content_params`

A dictionary of key/value parameters included in the `CONTENT_TYPE` header.

`HttpRequest.GET`

A dictionary-like object containing all given HTTP GET parameters. See the *QueryDict* documentation below.

`HttpRequest.POST`

A dictionary-like object containing all given HTTP POST parameters, providing that the request contains form data. See the *QueryDict* documentation below. If you need to access raw or non-form data posted in the request, access this through the `HttpRequest.body` attribute instead.

It's possible that a request can come in via POST with an empty POST dictionary –if, say, a form is requested via the POST HTTP method but does not include form data. Therefore, you shouldn't use `if request.POST` to check for use of the POST method; instead, use `if request.method == "POST"` (see *HttpRequest.method*).

POST does not include file-upload information. See *FILES*.

`HttpRequest.COOKIES`

A dictionary containing all cookies. Keys and values are strings.

`HttpRequest.FILES`

A dictionary-like object containing all uploaded files. Each key in `FILES` is the name from the `<input type="file" name=">`. Each value in `FILES` is an *UploadedFile*.

See *Managing files* for more information.

`FILES` will only contain data if the request method was POST and the `<form>` that posted to the request had `enctype="multipart/form-data"`. Otherwise, `FILES` will be a blank dictionary-like object.

`HttpRequest.META`

A dictionary containing all available HTTP headers. Available headers depend on the client and server, but here are some examples:

- `CONTENT_LENGTH` –The length of the request body (as a string).
- `CONTENT_TYPE` –The MIME type of the request body.
- `HTTP_ACCEPT` –Acceptable content types for the response.
- `HTTP_ACCEPT_ENCODING` –Acceptable encodings for the response.
- `HTTP_ACCEPT_LANGUAGE` –Acceptable languages for the response.
- `HTTP_HOST` –The HTTP Host header sent by the client.
- `HTTP_REFERER` –The referring page, if any.
- `HTTP_USER_AGENT` –The client’s user-agent string.
- `QUERY_STRING` –The query string, as a single (unparsed) string.
- `REMOTE_ADDR` –The IP address of the client.
- `REMOTE_HOST` –The hostname of the client.
- `REMOTE_USER` –The user authenticated by the web server, if any.
- `REQUEST_METHOD` –A string such as "GET" or "POST".
- `SERVER_NAME` –The hostname of the server.
- `SERVER_PORT` –The port of the server (as a string).

With the exception of `CONTENT_LENGTH` and `CONTENT_TYPE`, as given above, any HTTP headers in the request are converted to `META` keys by converting all characters to uppercase, replacing any hyphens with underscores and adding an `HTTP_` prefix to the name. So, for example, a header called `X-Bender` would be mapped to the `META` key `HTTP_X_BENDER`.

Note that *runserver* strips all headers with underscores in the name, so you won’t see them in `META`. This prevents header-spoofing based on ambiguity between underscores and dashes both being normalizing to underscores in WSGI environment variables. It matches the behavior of web servers like Nginx and Apache 2.4+.

`HttpRequest.headers` is a simpler way to access all HTTP-prefixed headers, plus `CONTENT_LENGTH` and `CONTENT_TYPE`.

`HttpRequest.headers`

A case insensitive, dict-like object that provides access to all HTTP-prefixed headers (plus `Content-Length` and `Content-Type`) from the request.

The name of each header is stylized with title-casing (e.g. `User-Agent`) when it’s displayed. You can access headers case-insensitively:

```
>>> request.headers
{'User-Agent': 'Mozilla/5.0 (Macintosh; Intel Mac OS X 10_12_6', ...}

>>> "User-Agent" in request.headers
True
>>> "user-agent" in request.headers
True

>>> request.headers["User-Agent"]
Mozilla/5.0 (Macintosh; Intel Mac OS X 10_12_6)
>>> request.headers["user-agent"]
Mozilla/5.0 (Macintosh; Intel Mac OS X 10_12_6)

>>> request.headers.get("User-Agent")
Mozilla/5.0 (Macintosh; Intel Mac OS X 10_12_6)
>>> request.headers.get("user-agent")
Mozilla/5.0 (Macintosh; Intel Mac OS X 10_12_6)
```

For use in, for example, Django templates, headers can also be looked up using underscores in place of hyphens:

```
{{ request.headers.user_agent }}
```

`HttpRequest.resolver_match`

An instance of *ResolverMatch* representing the resolved URL. This attribute is only set after URL resolving took place, which means it's available in all views but not in middleware which are executed before URL resolving takes place (you can use it in *process_view()* though).

Attributes set by application code

Django doesn't set these attributes itself but makes use of them if set by your application.

`HttpRequest.current_app`

The *url* template tag will use its value as the *current_app* argument to *reverse()*.

`HttpRequest.urlconf`

This will be used as the root URLconf for the current request, overriding the *ROOT_URLCONF* setting. See [How Django processes a request](#) for details.

urlconf can be set to *None* to revert any changes made by previous middleware and return to using the *ROOT_URLCONF*.

`HttpRequest.exception_reporter_filter`

This will be used instead of *DEFAULT_EXCEPTION_REPORTER_FILTER* for the current request. See [Custom error reports](#) for details.

`HttpRequest.exception_reporter_class`

This will be used instead of `DEFAULT_EXCEPTION_REPORTER` for the current request. See [Custom error reports](#) for details.

Attributes set by middleware

Some of the middleware included in Django's contrib apps set attributes on the request. If you don't see the attribute on a request, be sure the appropriate middleware class is listed in [MIDDLEWARE](#).

`HttpRequest.session`

From the [SessionMiddleware](#): A readable and writable, dictionary-like object that represents the current session.

`HttpRequest.site`

From the [CurrentSiteMiddleware](#): An instance of [Site](#) or [RequestSite](#) as returned by [get_current_site\(\)](#) representing the current site.

`HttpRequest.user`

From the [AuthenticationMiddleware](#): An instance of [AUTH_USER_MODEL](#) representing the currently logged-in user. If the user isn't currently logged in, `user` will be set to an instance of [AnonymousUser](#). You can tell them apart with `is_authenticated`, like so:

```
if request.user.is_authenticated:
    ... # Do something for logged-in users.
else:
    ... # Do something for anonymous users.
```

Methods

`HttpRequest.get_host()`

Returns the originating host of the request using information from the `HTTP_X_FORWARDED_HOST` (if [USE_X_FORWARDED_HOST](#) is enabled) and `HTTP_HOST` headers, in that order. If they don't provide a value, the method uses a combination of `SERVER_NAME` and `SERVER_PORT` as detailed in [PEP 3333](#).

Example: `"127.0.0.1:8000"`

Raises `django.core.exceptions.DisallowedHost` if the host is not in [ALLOWED_HOSTS](#) or the domain name is invalid according to [RFC 1034/1035](#).

Note: The `get_host()` method fails when the host is behind multiple proxies. One solution is to use middleware to rewrite the proxy headers, as in the following example:

```
class MultipleProxyMiddleware:
    FORWARDED_FOR_FIELDS = [
        "HTTP_X_FORWARDED_FOR",
        "HTTP_X_FORWARDED_HOST",
        "HTTP_X_FORWARDED_SERVER",
    ]

    def __init__(self, get_response):
        self.get_response = get_response

    def __call__(self, request):
        """
        Rewrites the proxy headers so that only the most
        recent proxy is used.
        """
        for field in self.FORWARDED_FOR_FIELDS:
            if field in request.META:
                if "," in request.META[field]:
                    parts = request.META[field].split(",")
                    request.META[field] = parts[-1].strip()
        return self.get_response(request)
```

This middleware should be positioned before any other middleware that relies on the value of `get_host()` –for instance, *CommonMiddleware* or *CsrfViewMiddleware*.

`HttpRequest.get_port()`

Returns the originating port of the request using information from the `HTTP_X_FORWARDED_PORT` (if `USE_X_FORWARDED_PORT` is enabled) and `SERVER_PORT` META variables, in that order.

`HttpRequest.get_full_path()`

Returns the path, plus an appended query string, if applicable.

Example: `"/music/bands/the_beatles/?print=true"`

`HttpRequest.get_full_path_info()`

Like `get_full_path()`, but uses *path_info* instead of *path*.

Example: `"/minfo/music/bands/the_beatles/?print=true"`

`HttpRequest.build_absolute_uri(location=None)`

Returns the absolute URI form of `location`. If no location is provided, the location will be set to `request.get_full_path()`.

If the location is already an absolute URI, it will not be altered. Otherwise the absolute URI is built using the server variables available in this request. For example:

```
>>> request.build_absolute_uri()
'https://example.com/music/bands/the_beatles/?print=true'
>>> request.build_absolute_uri('/bands/')
'https://example.com/bands/'
>>> request.build_absolute_uri('https://example2.com/bands/')
'https://example2.com/bands/'
```

Note: Mixing HTTP and HTTPS on the same site is discouraged, therefore `build_absolute_uri()` will always generate an absolute URI with the same scheme the current request has. If you need to redirect users to HTTPS, it's best to let your web server redirect all HTTP traffic to HTTPS.

`HttpRequest.get_signed_cookie(key, default=RAISE_ERROR, salt='', max_age=None)`

Returns a cookie value for a signed cookie, or raises a `django.core.signing.BadSignature` exception if the signature is no longer valid. If you provide the `default` argument the exception will be suppressed and that default value will be returned instead.

The optional `salt` argument can be used to provide extra protection against brute force attacks on your secret key. If supplied, the `max_age` argument will be checked against the signed timestamp attached to the cookie value to ensure the cookie is not older than `max_age` seconds.

For example:

```
>>> request.get_signed_cookie("name")
'Tony'
>>> request.get_signed_cookie("name", salt="name-salt")
'Tony' # assuming cookie was set using the same salt
>>> request.get_signed_cookie("nonexistent-cookie")
KeyError: 'nonexistent-cookie'
>>> request.get_signed_cookie("nonexistent-cookie", False)
False
>>> request.get_signed_cookie("cookie-that-was-tampered-with")
BadSignature: ...
>>> request.get_signed_cookie("name", max_age=60)
SignatureExpired: Signature age 1677.3839159 > 60 seconds
>>> request.get_signed_cookie("name", False, max_age=60)
False
```

See [cryptographic signing](#) for more information.

`HttpRequest.is_secure()`

Returns `True` if the request is secure; that is, if it was made with HTTPS.

`HttpRequest.accepts(mime_type)`

Returns `True` if the request Accept header matches the `mime_type` argument:

```
>>> request.accepts("text/html")
True
```

Most browsers send `Accept: */*` by default, so this would return `True` for all content types. Setting an explicit `Accept` header in API requests can be useful for returning a different content type for those consumers only. See [Content negotiation example](#) of using `accepts()` to return different content to API consumers.

If a response varies depending on the content of the `Accept` header and you are using some form of caching like Django's [cache middleware](#), you should decorate the view with [vary_on_headers\('Accept'\)](#) so that the responses are properly cached.

`HttpRequest.read(size=None)`

`HttpRequest.readline()`

`HttpRequest.readlines()`

`HttpRequest.__iter__()`

Methods implementing a file-like interface for reading from an `HttpRequest` instance. This makes it possible to consume an incoming request in a streaming fashion. A common use-case would be to process a big XML payload with an iterative parser without constructing a whole XML tree in memory.

Given this standard interface, an `HttpRequest` instance can be passed directly to an XML parser such as [ElementTree](#):

```
import xml.etree.ElementTree as ET

for element in ET.iterparse(request):
    process(element)
```

6.18.3 QueryDict objects

`class QueryDict`

In an [HttpRequest](#) object, the [GET](#) and [POST](#) attributes are instances of `django.http.QueryDict`, a dictionary-like class customized to deal with multiple values for the same key. This is necessary because some HTML form elements, notably `<select multiple>`, pass multiple values for the same key.

The `QueryDict`s at `request.POST` and `request.GET` will be immutable when accessed in a normal request/response cycle. To get a mutable version you need to use [QueryDict.copy\(\)](#).

Methods

QueryDict implements all the standard dictionary methods because it's a subclass of dictionary. Exceptions are outlined here:

`QueryDict.__init__(query_string=None, mutable=False, encoding=None)`

Instantiates a *QueryDict* object based on *query_string*.

```
>>> QueryDict('a=1&a=2&c=3')
<QueryDict: {'a': ['1', '2'], 'c': ['3']}>
```

If *query_string* is not passed in, the resulting *QueryDict* will be empty (it will have no keys or values).

Most *QueryDict*s you encounter, and in particular those at `request.POST` and `request.GET`, will be immutable. If you are instantiating one yourself, you can make it mutable by passing `mutable=True` to its `__init__()`.

Strings for setting both keys and values will be converted from *encoding* to *str*. If *encoding* is not set, it defaults to *DEFAULT_CHARSET*.

`classmethod QueryDict.fromkeys(iterable, value="", mutable=False, encoding=None)`

Creates a new *QueryDict* with keys from *iterable* and each value equal to *value*. For example:

```
>>> QueryDict.fromkeys(["a", "a", "b"], value="val")
<QueryDict: {'a': ['val', 'val'], 'b': ['val']}>
```

`QueryDict.__getitem__(key)`

Returns the value for the given key. If the key has more than one value, it returns the last value. Raises `django.utils.datastructures.MultiValueDictKeyError` if the key does not exist. (This is a subclass of Python's standard `KeyError`, so you can stick to catching `KeyError`.)

`QueryDict.__setitem__(key, value)`

Sets the given key to `[value]` (a list whose single element is *value*). Note that this, as other dictionary functions that have side effects, can only be called on a mutable *QueryDict* (such as one that was created via *QueryDict.copy()*).

`QueryDict.__contains__(key)`

Returns True if the given key is set. This lets you do, e.g., `if "foo" in request.GET`.

`QueryDict.get(key, default=None)`

Uses the same logic as `__getitem__()`, with a hook for returning a default value if the key doesn't exist.

`QueryDict.setdefault(key, default=None)`

Like `dict.setdefault()`, except it uses `__setitem__()` internally.

`QueryDict.update(other_dict)`

Takes either a `QueryDict` or a dictionary. Like `dict.update()`, except it appends to the current dictionary items rather than replacing them. For example:

```
>>> q = QueryDict("a=1", mutable=True)
>>> q.update({"a": "2"})
>>> q.getlist("a")
['1', '2']
>>> q["a"] # returns the last
'2'
```

`QueryDict.items()`

Like `dict.items()`, except this uses the same last-value logic as `__getitem__()` and returns an iterator object instead of a view object. For example:

```
>>> q = QueryDict("a=1&a=2&a=3")
>>> list(q.items())
[('a', '3')]
```

`QueryDict.values()`

Like `dict.values()`, except this uses the same last-value logic as `__getitem__()` and returns an iterator instead of a view object. For example:

```
>>> q = QueryDict("a=1&a=2&a=3")
>>> list(q.values())
['3']
```

In addition, `QueryDict` has the following methods:

`QueryDict.copy()`

Returns a copy of the object using `copy.deepcopy()`. This copy will be mutable even if the original was not.

`QueryDict.getlist(key, default=None)`

Returns a list of the data with the requested key. Returns an empty list if the key doesn't exist and `default` is `None`. It's guaranteed to return a list unless the default value provided isn't a list.

`QueryDict.setlist(key, list_)`

Sets the given key to `list_` (unlike `__setitem__()`).

`QueryDict.appendlist(key, item)`

Appends an item to the internal list associated with key.

`QueryDict.setlistdefault(key, default_list=None)`

Like `setdefault()`, except it takes a list of values instead of a single value.

QueryDict.lists()

Like *items()*, except it includes all values, as a list, for each member of the dictionary. For example:

```
>>> q = QueryDict("a=1&a=2&a=3")
>>> q.lists()
[('a', ['1', '2', '3'])]
```

QueryDict.pop(key)

Returns a list of values for the given key and removes them from the dictionary. Raises `KeyError` if the key does not exist. For example:

```
>>> q = QueryDict("a=1&a=2&a=3", mutable=True)
>>> q.pop("a")
['1', '2', '3']
```

QueryDict.popitem()

Removes an arbitrary member of the dictionary (since there's no concept of ordering), and returns a two value tuple containing the key and a list of all values for the key. Raises `KeyError` when called on an empty dictionary. For example:

```
>>> q = QueryDict("a=1&a=2&a=3", mutable=True)
>>> q.popitem()
('a', ['1', '2', '3'])
```

QueryDict.dict()

Returns a dict representation of `QueryDict`. For every (key, list) pair in `QueryDict`, `dict` will have (key, item), where item is one element of the list, using the same logic as *QueryDict.__getitem__()*:

```
>>> q = QueryDict("a=1&a=3&a=5")
>>> q.dict()
{'a': '5'}
```

QueryDict.urlencode(safe=None)

Returns a string of the data in query string format. For example:

```
>>> q = QueryDict("a=2&b=3&b=5")
>>> q.urlencode()
'a=2&b=3&b=5'
```

Use the `safe` parameter to pass characters which don't require encoding. For example:

```
>>> q = QueryDict(mutable=True)
>>> q["next"] = "/a&b/"
```

(continues on next page)

(continued from previous page)

```
>>> q.urlencode(safe="/")
'next=/a%26b/'
```

6.18.4 `HttpResponse` objects

`class HttpResponse`

In contrast to *HttpRequest* objects, which are created automatically by Django, *HttpResponse* objects are your responsibility. Each view you write is responsible for instantiating, populating, and returning an *HttpResponse*.

The *HttpResponse* class lives in the *django.http* module.

Usage

Passing strings

Typical usage is to pass the contents of the page, as a string, bytestring, or *memoryview*, to the *HttpResponse* constructor:

```
>>> from django.http import HttpResponse
>>> response = HttpResponse("Here's the text of the web page.")
>>> response = HttpResponse("Text only, please.", content_type="text/plain")
>>> response = HttpResponse(b"Bytestrings are also accepted.")
>>> response = HttpResponse(memoryview(b"Memoryview as well."))
```

But if you want to add content incrementally, you can use `response` as a file-like object:

```
>>> response = HttpResponse()
>>> response.write("<p>Here's the text of the web page.</p>")
>>> response.write("<p>Here's another paragraph.</p>")
```

Passing iterators

Finally, you can pass *HttpResponse* an iterator rather than strings. *HttpResponse* will consume the iterator immediately, store its content as a string, and discard it. Objects with a `close()` method such as files and generators are immediately closed.

If you need the response to be streamed from the iterator to the client, you must use the *StreamingHttpResponse* class instead.

Setting header fields

To set or remove a header field in your response, use `HttpResponse.headers`:

```
>>> response = HttpResponse()
>>> response.headers["Age"] = 120
>>> del response.headers["Age"]
```

You can also manipulate headers by treating your response like a dictionary:

```
>>> response = HttpResponse()
>>> response["Age"] = 120
>>> del response["Age"]
```

This proxies to `HttpResponse.headers`, and is the original interface offered by `HttpResponse`.

When using this interface, unlike a dictionary, `del` doesn't raise `KeyError` if the header field doesn't exist.

You can also set headers on instantiation:

```
>>> response = HttpResponse(headers={"Age": 120})
```

For setting the `Cache-Control` and `Vary` header fields, it is recommended to use the `patch_cache_control()` and `patch_vary_headers()` methods from `django.utils.cache`, since these fields can have multiple, comma-separated values. The “patch” methods ensure that other values, e.g. added by a middleware, are not removed.

HTTP header fields cannot contain newlines. An attempt to set a header field containing a newline character (CR or LF) will raise `BadHeaderError`

Telling the browser to treat the response as a file attachment

To tell the browser to treat the response as a file attachment, set the `Content-Type` and `Content-Disposition` headers. For example, this is how you might return a Microsoft Excel spreadsheet:

```
>>> response = HttpResponse(
...     my_data,
...     headers={
...         "Content-Type": "application/vnd.ms-excel",
...         "Content-Disposition": 'attachment; filename="foo.xls"',
...     },
... )
```

There's nothing Django-specific about the `Content-Disposition` header, but it's easy to forget the syntax, so we've included it here.

Attributes

`HttpResponse.content`

A bytestring representing the content, encoded from a string if necessary.

`HttpResponse.headers`

A case insensitive, dict-like object that provides an interface to all HTTP headers on the response. See [Setting header fields](#).

`HttpResponse.charset`

A string denoting the charset in which the response will be encoded. If not given at `HttpResponse` instantiation time, it will be extracted from `content_type` and if that is unsuccessful, the `DEFAULT_CHARSET` setting will be used.

`HttpResponse.status_code`

The [HTTP status code](#) for the response.

Unless `reason_phrase` is explicitly set, modifying the value of `status_code` outside the constructor will also modify the value of `reason_phrase`.

`HttpResponse.reason_phrase`

The HTTP reason phrase for the response. It uses the [HTTP standard](#)'s default reason phrases.

Unless explicitly set, `reason_phrase` is determined by the value of `status_code`.

`HttpResponse.streaming`

This is always `False`.

This attribute exists so middleware can treat streaming responses differently from regular responses.

`HttpResponse.closed`

`True` if the response has been closed.

Methods

`HttpResponse.__init__(content=b'', content_type=None, status=200, reason=None, charset=None, headers=None)`

Instantiates an `HttpResponse` object with the given page content, content type, and headers.

`content` is most commonly an iterator, bytestring, [memoryview](#), or string. Other types will be converted to a bytestring by encoding their string representation. Iterators should return strings or bytestrings and those will be joined together to form the content of the response.

`content_type` is the MIME type optionally completed by a character set encoding and is used to fill the HTTP Content-Type header. If not specified, it is formed by `'text/html'` and the `DEFAULT_CHARSET` settings, by default: `"text/html; charset=utf-8"`.

`status` is the [HTTP status code](#) for the response. You can use Python's `http.HTTPStatus` for meaningful aliases, such as `HTTPStatus.NO_CONTENT`.

`reason` is the HTTP response phrase. If not provided, a default phrase will be used.

`charset` is the charset in which the response will be encoded. If not given it will be extracted from `content_type`, and if that is unsuccessful, the [DEFAULT_CHARSET](#) setting will be used.

`headers` is a [dict](#) of HTTP headers for the response.

`HttpResponse.__setitem__(header, value)`

Sets the given header name to the given value. Both `header` and `value` should be strings.

`HttpResponse.__delitem__(header)`

Deletes the header with the given name. Fails silently if the header doesn't exist. Case-insensitive.

`HttpResponse.__getitem__(header)`

Returns the value for the given header name. Case-insensitive.

`HttpResponse.get(header, alternate=None)`

Returns the value for the given header, or an `alternate` if the header doesn't exist.

`HttpResponse.has_header(header)`

Returns `True` or `False` based on a case-insensitive check for a header with the given name.

`HttpResponse.items()`

Acts like `dict.items()` for HTTP headers on the response.

`HttpResponse.setdefault(header, value)`

Sets a header unless it has already been set.

`HttpResponse.set_cookie(key, value='', max_age=None, expires=None, path='/', domain=None, secure=False, httponly=False, samesite=None)`

Sets a cookie. The parameters are the same as in the [Morsel](#) cookie object in the Python standard library.

- `max_age` should be a [timedelta](#) object, an integer number of seconds, or `None` (default) if the cookie should last only as long as the client's browser session. If `expires` is not specified, it will be calculated.

Support for `timedelta` objects was added.

- `expires` should either be a string in the format "Wdy, DD-Mon-YY HH:MM:SS GMT" or a `datetime.datetime` object in UTC. If `expires` is a `datetime` object, the `max_age` will be calculated.
- Use `domain` if you want to set a cross-domain cookie. For example, `domain="example.com"` will set a cookie that is readable by the domains `www.example.com`, `blog.example.com`, etc. Otherwise, a cookie will only be readable by the domain that set it.

- Use `secure=True` if you want the cookie to be only sent to the server when a request is made with the `https` scheme.
- Use `httponly=True` if you want to prevent client-side JavaScript from having access to the cookie.

`HttpOnly` is a flag included in a Set-Cookie HTTP response header. It's part of the [RFC 6265](#) standard for cookies and can be a useful way to mitigate the risk of a client-side script accessing the protected cookie data.

- Use `samesite='Strict'` or `samesite='Lax'` to tell the browser not to send this cookie when performing a cross-origin request. `SameSite` isn't supported by all browsers, so it's not a replacement for Django's CSRF protection, but rather a defense in depth measure.

Use `samesite='None'` (string) to explicitly state that this cookie is sent with all same-site and cross-site requests.

Warning: [RFC 6265](#) states that user agents should support cookies of at least 4096 bytes. For many browsers this is also the maximum size. Django will not raise an exception if there's an attempt to store a cookie of more than 4096 bytes, but many browsers will not set the cookie correctly.

```
HttpResponse.set_signed_cookie(key, value, salt='', max_age=None, expires=None, path='/',
                               domain=None, secure=False, httponly=False, samesite=None)
```

Like `set_cookie()`, but [cryptographic signing](#) the cookie before setting it. Use in conjunction with `HttpRequest.get_signed_cookie()`. You can use the optional `salt` argument for added key strength, but you will need to remember to pass it to the corresponding `HttpRequest.get_signed_cookie()` call.

```
HttpResponse.delete_cookie(key, path='/', domain=None, samesite=None)
```

Deletes the cookie with the given key. Fails silently if the key doesn't exist.

Due to the way cookies work, `path` and `domain` should be the same values you used in `set_cookie()` – otherwise the cookie may not be deleted.

```
HttpResponse.close()
```

This method is called at the end of the request directly by the WSGI server.

```
HttpResponse.write(content)
```

This method makes an `HttpResponse` instance a file-like object.

```
HttpResponse.flush()
```

This method makes an `HttpResponse` instance a file-like object.

```
HttpResponse.tell()
```

This method makes an `HttpResponse` instance a file-like object.

`HttpResponse.getvalue()`

Returns the value of `HttpResponse.content`. This method makes an `HttpResponse` instance a stream-like object.

`HttpResponse.readable()`

Always `False`. This method makes an `HttpResponse` instance a stream-like object.

`HttpResponse.seekable()`

Always `False`. This method makes an `HttpResponse` instance a stream-like object.

`HttpResponse.writable()`

Always `True`. This method makes an `HttpResponse` instance a stream-like object.

`HttpResponse.writelines(lines)`

Writes a list of lines to the response. Line separators are not added. This method makes an `HttpResponse` instance a stream-like object.

`HttpResponse` subclasses

Django includes a number of `HttpResponse` subclasses that handle different types of HTTP responses. Like `HttpResponse`, these subclasses live in `django.http`.

class `HttpResponseRedirect`

The first argument to the constructor is required –the path to redirect to. This can be a fully qualified URL (e.g. `'https://www.yahoo.com/search/'`), an absolute path with no domain (e.g. `'/search/'`), or even a relative path (e.g. `'search/'`). In that last case, the client browser will reconstruct the full URL itself according to the current path. See `HttpResponse` for other optional constructor arguments. Note that this returns an HTTP status code 302.

`url`

This read-only attribute represents the URL the response will redirect to (equivalent to the `Location` response header).

class `HttpResponsePermanentRedirect`

Like `HttpResponseRedirect`, but it returns a permanent redirect (HTTP status code 301) instead of a “found” redirect (status code 302).

class `HttpResponseNotModified`

The constructor doesn't take any arguments and no content should be added to this response. Use this to designate that a page hasn't been modified since the user's last request (status code 304).

class `HttpResponseBadRequest`

Acts just like `HttpResponse` but uses a 400 status code.

```
class HttpResponseNotFound
```

Acts just like *HttpResponse* but uses a 404 status code.

```
class HttpResponseForbidden
```

Acts just like *HttpResponse* but uses a 403 status code.

```
class HttpResponseNotAllowed
```

Like *HttpResponse*, but uses a 405 status code. The first argument to the constructor is required: a list of permitted methods (e.g. ['GET', 'POST']).

```
class HttpResponseGone
```

Acts just like *HttpResponse* but uses a 410 status code.

```
class HttpResponseServerError
```

Acts just like *HttpResponse* but uses a 500 status code.

Note: If a custom subclass of *HttpResponse* implements a `render` method, Django will treat it as emulating a *SimpleTemplateResponse*, and the `render` method must itself return a valid response object.

Custom response classes

If you find yourself needing a response class that Django doesn't provide, you can create it with the help of `http.HTTPStatus`. For example:

```
from http import HTTPStatus
from django.http import HttpResponse

class HttpResponseNoContent(HttpResponse):
    status_code = HTTPStatus.NO_CONTENT
```

6.18.5 JsonResponse objects

```
class JsonResponse(data, encoder=DjangoJSONEncoder, safe=True, json_dumps_params=None,
                  **kwargs)
```

An *HttpResponse* subclass that helps to create a JSON-encoded response. It inherits most behavior from its superclass with a couple differences:

Its default Content-Type header is set to *application/json*.

The first parameter, `data`, should be a `dict` instance. If the `safe` parameter is set to `False` (see below) it can be any JSON-serializable object.

The encoder, which defaults to `django.core.serializers.json.DjangoJSONEncoder`, will be used to serialize the data. See [JSON serialization](#) for more details about this serializer.

The `safe` boolean parameter defaults to `True`. If it's set to `False`, any object can be passed for serialization (otherwise only `dict` instances are allowed). If `safe` is `True` and a non-`dict` object is passed as the first argument, a `TypeError` will be raised.

The `json_dumps_params` parameter is a dictionary of keyword arguments to pass to the `json.dumps()` call used to generate the response.

Usage

Typical usage could look like:

```
>>> from django.http import JsonResponse
>>> response = JsonResponse({"foo": "bar"})
>>> response.content
b'{"foo": "bar"}'
```

Serializing non-dictionary objects

In order to serialize objects other than `dict` you must set the `safe` parameter to `False`:

```
>>> response = JsonResponse([1, 2, 3], safe=False)
```

Without passing `safe=False`, a `TypeError` will be raised.

Note that an API based on `dict` objects is more extensible, flexible, and makes it easier to maintain forwards compatibility. Therefore, you should avoid using non-`dict` objects in JSON-encoded response.

Warning: Before the [5th edition of ECMAScript](#) it was possible to poison the JavaScript `Array` constructor. For this reason, Django does not allow passing non-`dict` objects to the `JsonResponse` constructor by default. However, most modern browsers implement ECMAScript 5 which removes this attack vector. Therefore it is possible to disable this security precaution.

Changing the default JSON encoder

If you need to use a different JSON encoder class you can pass the `encoder` parameter to the constructor method:

```
>>> response = JsonResponse(data, encoder=MyJSONEncoder)
```

6.18.6 StreamingHttpResponse objects

class `StreamingHttpResponse`

The *`StreamingHttpResponse`* class is used to stream a response from Django to the browser.

Advanced usage

`StreamingHttpResponse` is somewhat advanced, in that it is important to know whether you'll be serving your application synchronously under WSGI or asynchronously under ASGI, and adjust your usage appropriately.

Please read these notes with care.

An example usage of *`StreamingHttpResponse`* under WSGI is streaming content when generating the response would take too long or uses too much memory. For instance, it's useful for [generating large CSV files](#).

There are performance considerations when doing this, though. Django, under WSGI, is designed for short-lived requests. Streaming responses will tie a worker process for the entire duration of the response. This may result in poor performance.

Generally speaking, you would perform expensive tasks outside of the request-response cycle, rather than resorting to a streamed response.

When serving under ASGI, however, a *`StreamingHttpResponse`* need not stop other requests from being served whilst waiting for I/O. This opens up the possibility of long-lived requests for streaming content and implementing patterns such as long-polling, and server-sent events.

Even under ASGI note, *`StreamingHttpResponse`* should only be used in situations where it is absolutely required that the whole content isn't iterated before transferring the data to the client. Because the content can't be accessed, many middleware can't function normally. For example the `ETag` and `Content-Length` headers can't be generated for streaming responses.

The *`StreamingHttpResponse`* is not a subclass of *`HttpResponse`*, because it features a slightly different API. However, it is almost identical, with the following notable differences:

- It should be given an iterator that yields bytestrings, `memoryview`, or strings as content. When serving under WSGI, this should be a sync iterator. When serving under ASGI, then it should be an async iterator.
- You cannot access its content, except by iterating the response object itself. This should only occur when the response is returned to the client: you should not iterate the response yourself.

Under WSGI the response will be iterated synchronously. Under ASGI the response will be iterated asynchronously. (This is why the iterator type must match the protocol you're using.)

To avoid a crash, an incorrect iterator type will be mapped to the correct type during iteration, and a warning will be raised, but in order to do this the iterator must be fully-consumed, which defeats the purpose of using a *StreamingHttpResponse* at all.

- It has no `content` attribute. Instead, it has a *streaming_content* attribute. This can be used in middleware to wrap the response iterable, but should not be consumed.
- You cannot use the file-like object `tell()` or `write()` methods. Doing so will raise an exception.

The *HttpResponseBase* base class is common between *HttpResponse* and *StreamingHttpResponse*.

Support for asynchronous iteration was added.

Attributes

`StreamingHttpResponse.streaming_content`

An iterator of the response content, bytestring encoded according to *HttpResponse.charset*.

`StreamingHttpResponse.status_code`

The HTTP status code for the response.

Unless *reason_phrase* is explicitly set, modifying the value of `status_code` outside the constructor will also modify the value of *reason_phrase*.

`StreamingHttpResponse.reason_phrase`

The HTTP reason phrase for the response. It uses the HTTP standard's default reason phrases.

Unless explicitly set, *reason_phrase* is determined by the value of *status_code*.

`StreamingHttpResponse.streaming`

This is always True.

`StreamingHttpResponse.is_async`

Boolean indicating whether *StreamingHttpResponse.streaming_content* is an asynchronous iterator or not.

This is useful for middleware needing to wrap *StreamingHttpResponse.streaming_content*.

6.18.7 FileResponse objects

`class FileResponse(open_file, as_attachment=False, filename='', **kwargs)`

FileResponse is a subclass of *StreamingHttpResponse* optimized for binary files. It uses `wsgi.file_wrapper` if provided by the wsgi server, otherwise it streams the file out in small chunks.

If `as_attachment=True`, the `Content-Disposition` header is set to `attachment`, which asks the browser to offer the file to the user as a download. Otherwise, a `Content-Disposition` header with a value of `inline` (the browser default) will be set only if a filename is available.

If `open_file` doesn't have a name or if the name of `open_file` isn't appropriate, provide a custom file name using the `filename` parameter. Note that if you pass a file-like object like `io.BytesIO`, it's your task to `seek()` it before passing it to `FileResponse`.

The `Content-Length` header is automatically set when it can be guessed from the content of `open_file`.

The `Content-Type` header is automatically set when it can be guessed from the `filename`, or the name of `open_file`.

`FileResponse` accepts any file-like object with binary content, for example a file open in binary mode like so:

```
>>> from django.http import FileResponse
>>> response = FileResponse(open("myfile.png", "rb"))
```

The file will be closed automatically, so don't open it with a context manager.

Use under ASGI

Python's file API is synchronous. This means that the file must be fully consumed in order to be served under ASGI.

In order to stream a file asynchronously you need to use a third-party package that provides an asynchronous file API, such as [aiofiles](#).

Methods

`FileResponse.set_headers(open_file)`

This method is automatically called during the response initialization and set various headers (`Content-Length`, `Content-Type`, and `Content-Disposition`) depending on `open_file`.

6.18.8 `HttpResponseBase` class

```
class HttpResponseBase
```

The `HttpResponseBase` class is common to all Django responses. It should not be used to create responses directly, but it can be useful for type-checking.

6.19 `SchemaEditor`

```
class BaseDatabaseSchemaEditor
```

Django’s migration system is split into two parts; the logic for calculating and storing what operations should be run (`django.db.migrations`), and the database abstraction layer that turns things like “create a model” or “delete a field” into SQL - which is the job of the `SchemaEditor`.

It’s unlikely that you will want to interact directly with `SchemaEditor` as a normal developer using Django, but if you want to write your own migration system, or have more advanced needs, it’s a lot nicer than writing SQL.

Each database backend in Django supplies its own version of `SchemaEditor`, and it’s always accessible via the `connection.schema_editor()` context manager:

```
with connection.schema_editor() as schema_editor:
    schema_editor.delete_model(MyModel)
```

It must be used via the context manager as this allows it to manage things like transactions and deferred SQL (like creating `ForeignKey` constraints).

It exposes all possible operations as methods, that should be called in the order you wish changes to be applied. Some possible operations or types of change are not possible on all databases - for example, MyISAM does not support foreign key constraints.

If you are writing or maintaining a third-party database backend for Django, you will need to provide a `SchemaEditor` implementation in order to work with Django’s migration functionality - however, as long as your database is relatively standard in its use of SQL and relational design, you should be able to subclass one of the built-in Django `SchemaEditor` classes and tweak the syntax a little.

6.19.1 Methods

`execute()`

`BaseDatabaseSchemaEditor.execute(sql, params=())`

Executes the SQL statement passed in, with parameters if supplied. This is a wrapper around the normal database cursors that allows capture of the SQL to a `.sql` file if the user wishes.

`create_model()`

`BaseDatabaseSchemaEditor.create_model(model)`

Creates a new table in the database for the provided model, along with any unique constraints or indexes it requires.

`delete_model()`

`BaseDatabaseSchemaEditor.delete_model(model)`

Drops the model's table in the database along with any unique constraints or indexes it has.

`add_index()`

`BaseDatabaseSchemaEditor.add_index(model, index)`

Adds index to model's table.

`remove_index()`

`BaseDatabaseSchemaEditor.remove_index(model, index)`

Removes index from model's table.

`rename_index()`

`BaseDatabaseSchemaEditor.rename_index(model, old_index, new_index)`

Renames `old_index` from model's table to `new_index`.

`add_constraint()`

`BaseDatabaseSchemaEditor.add_constraint(model, constraint)`

Adds constraint to model's table.

`remove_constraint()`

`BaseDatabaseSchemaEditor.remove_constraint(model, constraint)`

Removes constraint from model's table.

`alter_unique_together()`

`BaseDatabaseSchemaEditor.alter_unique_together(model, old_unique_together,
new_unique_together)`

Changes a model's *unique_together* value; this will add or remove unique constraints from the model's table until they match the new value.

`alter_index_together()`

`BaseDatabaseSchemaEditor.alter_index_together(model, old_index_together, new_index_together)`

Changes a model's *index_together* value; this will add or remove indexes from the model's table until they match the new value.

`alter_db_table()`

`BaseDatabaseSchemaEditor.alter_db_table(model, old_db_table, new_db_table)`

Renames the model's table from `old_db_table` to `new_db_table`.

`alter_db_table_comment()`

`BaseDatabaseSchemaEditor.alter_db_table_comment(model, old_db_table_comment,
new_db_table_comment)`

Change the model's table comment to `new_db_table_comment`.

`alter_db_tablespace()`

`BaseDatabaseSchemaEditor.alter_db_tablespace(model, old_db_tablespace, new_db_tablespace)`

Moves the model's table from one tablespace to another.

`add_field()`

`BaseDatabaseSchemaEditor.add_field(model, field)`

Adds a column (or sometimes multiple) to the model's table to represent the field. This will also add indexes or a unique constraint if the field has `db_index=True` or `unique=True`.

If the field is a `ManyToManyField` without a value for `through`, instead of creating a column, it will make a table to represent the relationship. If `through` is provided, it is a no-op.

If the field is a `ForeignKey`, this will also add the foreign key constraint to the column.

`remove_field()`

`BaseDatabaseSchemaEditor.remove_field(model, field)`

Removes the column(s) representing the field from the model's table, along with any unique constraints, foreign key constraints, or indexes caused by that field.

If the field is a `ManyToManyField` without a value for `through`, it will remove the table created to track the relationship. If `through` is provided, it is a no-op.

`alter_field()`

`BaseDatabaseSchemaEditor.alter_field(model, old_field, new_field, strict=False)`

This transforms the field on the model from the old field to the new one. This includes changing the name of the column (the `db_column` attribute), changing the type of the field (if the field class changes), changing the NULL status of the field, adding or removing field-only unique constraints and indexes, changing primary key, and changing the destination of `ForeignKey` constraints.

The most common transformation this cannot do is transforming a `ManyToManyField` into a normal `Field` or vice-versa; Django cannot do this without losing data, and so it will refuse to do it. Instead, `remove_field()` and `add_field()` should be called separately.

If the database has the `supports_combined_alters`, Django will try and do as many of these in a single database call as possible; otherwise, it will issue a separate ALTER statement for each change, but will not issue ALTERs where no change is required.

6.19.2 Attributes

All attributes should be considered read-only unless stated otherwise.

`connection`

`SchemaEditor.connection`

A connection object to the database. A useful attribute of the connection is `alias` which can be used to determine the name of the database being accessed.

This is useful when doing data migrations for [migrations with multiple databases](#).

6.20 Settings

- [Core Settings](#)
- [Auth](#)
- [Messages](#)
- [Sessions](#)
- [Sites](#)
- [Static Files](#)
- [Core Settings Topical Index](#)

Warning: Be careful when you override settings, especially when the default value is a non-empty list or dictionary, such as `STATICFILES_FINDERS`. Make sure you keep the components required by the features of Django you wish to use.

6.20.1 Core Settings

Here's a list of settings available in Django core and their default values. Settings provided by contrib apps are listed below, followed by a topical index of the core settings. For introductory material, see the [settings topic guide](#).

ABSOLUTE_URL_OVERRIDES

Default: {} (Empty dictionary)

A dictionary mapping "app_label.model_name" strings to functions that take a model object and return its URL. This is a way of inserting or overriding `get_absolute_url()` methods on a per-installation basis.

Example:

```
ABSOLUTE_URL_OVERRIDES = {
    "blogs.blog": lambda o: "/blogs/%s/" % o.slug,
    "news.story": lambda o: "/stories/%s/%s/" % (o.pub_year, o.slug),
}
```

The model name used in this setting should be all lowercase, regardless of the case of the actual model class name.

ADMINS

Default: [] (Empty list)

A list of all the people who get code error notifications. When `DEBUG=False` and `AdminEmailHandler` is configured in `LOGGING` (done by default), Django emails these people the details of exceptions raised in the request/response cycle.

Each item in the list should be a tuple of (Full name, email address). Example:

```
[("John", "john@example.com"), ("Mary", "mary@example.com")]
```

ALLOWED_HOSTS

Default: [] (Empty list)

A list of strings representing the host/domain names that this Django site can serve. This is a security measure to prevent [HTTP Host header attacks](#), which are possible even under many seemingly-safe web server configurations.

Values in this list can be fully qualified names (e.g. `'www.example.com'`), in which case they will be matched against the request's `Host` header exactly (case-insensitive, not including port). A value beginning with a period can be used as a subdomain wildcard: `'.example.com'` will match `example.com`, `www.example.com`, and any other subdomain of `example.com`. A value of `'*'` will match anything; in this case you are responsible to provide your own validation of the `Host` header (perhaps in a middleware; if so this middleware must be listed first in [MIDDLEWARE](#)).

Django also allows the [fully qualified domain name \(FQDN\)](#) of any entries. Some browsers include a trailing dot in the `Host` header which Django strips when performing host validation.

If the `Host` header (or `X-Forwarded-Host` if `USE_X_FORWARDED_HOST` is enabled) does not match any value in this list, the `django.http.HttpRequest.get_host()` method will raise `SuspiciousOperation`.

When `DEBUG` is `True` and `ALLOWED_HOSTS` is empty, the host is validated against `['.localhost', '127.0.0.1', ':::1']`.

`ALLOWED_HOSTS` is also checked when running tests.

This validation only applies via `get_host()`; if your code accesses the `Host` header directly from `request.META` you are bypassing this security protection.

APPEND_SLASH

Default: `True`

When set to `True`, if the request URL does not match any of the patterns in the `URLconf` and it doesn't end in a slash, an HTTP redirect is issued to the same URL with a slash appended. Note that the redirect may cause any data submitted in a POST request to be lost.

The `APPEND_SLASH` setting is only used if `CommonMiddleware` is installed (see [Middleware](#)). See also `PREPEND_WWW`.

CACHES

Default:

```
{
    "default": {
        "BACKEND": "django.core.cache.backends.locmem.LocMemCache",
    }
}
```

A dictionary containing the settings for all caches to be used with Django. It is a nested dictionary whose contents maps cache aliases to a dictionary containing the options for an individual cache.

The `CACHES` setting must configure a `default` cache; any number of additional caches may also be specified. If you are using a cache backend other than the local memory cache, or you need to define multiple caches, other options will be required. The following cache options are available.

BACKEND

Default: '' (Empty string)

The cache backend to use. The built-in cache backends are:

- `'django.core.cache.backends.db.DatabaseCache'`
- `'django.core.cache.backends.dummy.DummyCache'`
- `'django.core.cache.backends.filebased.FileBasedCache'`
- `'django.core.cache.backends.locmem.LocMemCache'`
- `'django.core.cache.backends.memcached.PyMemcacheCache'`
- `'django.core.cache.backends.memcached.PyLibMCCache'`
- `'django.core.cache.backends.redis.RedisCache'`

You can use a cache backend that doesn't ship with Django by setting `BACKEND` to a fully-qualified path of a cache backend class (i.e. `mypackage.backends.whatever.WhateverCache`).

KEY_FUNCTION

A string containing a dotted path to a function (or any callable) that defines how to compose a prefix, version and key into a final cache key. The default implementation is equivalent to the function:

```
def make_key(key, key_prefix, version):
    return ":".join([key_prefix, str(version), key])
```

You may use any key function you want, as long as it has the same argument signature.

See the [cache documentation](#) for more information.

KEY_PREFIX

Default: '' (Empty string)

A string that will be automatically included (prepended by default) to all cache keys used by the Django server.

See the [cache documentation](#) for more information.

LOCATION

Default: '' (Empty string)

The location of the cache to use. This might be the directory for a file system cache, a host and port for a memcache server, or an identifying name for a local memory cache. e.g.:

```
CACHES = {
    "default": {
        "BACKEND": "django.core.cache.backends.filebased.FileBasedCache",
        "LOCATION": "/var/tmp/django_cache",
    }
}
```

OPTIONS

Default: None

Extra parameters to pass to the cache backend. Available parameters vary depending on your cache backend.

Some information on available parameters can be found in the [cache arguments](#) documentation. For more information, consult your backend module's own documentation.

TIMEOUT

Default: 300

The number of seconds before a cache entry is considered stale. If the value of this setting is `None`, cache entries will not expire. A value of 0 causes keys to immediately expire (effectively “don't cache”).

VERSION

Default: 1

The default version number for cache keys generated by the Django server.

See the [cache documentation](#) for more information.

CACHE_MIDDLEWARE_ALIAS

Default: 'default'

The cache connection to use for the [cache middleware](#).

CACHE_MIDDLEWARE_KEY_PREFIX

Default: '' (Empty string)

A string which will be prefixed to the cache keys generated by the [cache middleware](#). This prefix is combined with the [KEY_PREFIX](#) setting; it does not replace it.

See Django's [cache framework](#).

CACHE_MIDDLEWARE_SECONDS

Default: 600

The default number of seconds to cache a page for the [cache middleware](#).

See Django's [cache framework](#).

CSRF_COOKIE_AGE

Default: 31449600 (approximately 1 year, in seconds)

The age of CSRF cookies, in seconds.

The reason for setting a long-lived expiration time is to avoid problems in the case of a user closing a browser or bookmarking a page and then loading that page from a browser cache. Without persistent cookies, the form submission would fail in this case.

Some browsers (specifically Internet Explorer) can disallow the use of persistent cookies or can have the indexes to the cookie jar corrupted on disk, thereby causing CSRF protection checks to (sometimes intermittently) fail. Change this setting to `None` to use session-based CSRF cookies, which keep the cookies in-memory instead of on persistent storage.

CSRF_COOKIE_DOMAIN

Default: `None`

The domain to be used when setting the CSRF cookie. This can be useful for easily allowing cross-subdomain requests to be excluded from the normal cross site request forgery protection. It should be set to a string such as `".example.com"` to allow a POST request from a form on one subdomain to be accepted by a view served from another subdomain.

Please note that the presence of this setting does not imply that Django's CSRF protection is safe from cross-subdomain attacks by default - please see the [CSRF limitations](#) section.

`CSRF_COOKIE_HTTPONLY`

Default: `False`

Whether to use `HttpOnly` flag on the CSRF cookie. If this is set to `True`, client-side JavaScript will not be able to access the CSRF cookie.

Designating the CSRF cookie as `HttpOnly` doesn't offer any practical protection because CSRF is only to protect against cross-domain attacks. If an attacker can read the cookie via JavaScript, they're already on the same domain as far as the browser knows, so they can do anything they like anyway. (XSS is a much bigger hole than CSRF.)

Although the setting offers little practical benefit, it's sometimes required by security auditors.

If you enable this and need to send the value of the CSRF token with an AJAX request, your JavaScript must pull the value [from a hidden CSRF token form input](#) instead of [from the cookie](#).

See [SESSION_COOKIE_HTTPONLY](#) for details on `HttpOnly`.

`CSRF_COOKIE_MASKED`

Default: `False`

Whether to mask the CSRF cookie. See [release notes](#) for usage details.

Deprecated since version 4.1: This transitional setting is deprecated and will be removed in Django 5.0.

`CSRF_COOKIE_NAME`

Default: `'csrftoken'`

The name of the cookie to use for the CSRF authentication token. This can be whatever you want (as long as it's different from the other cookie names in your application). See [Cross Site Request Forgery protection](#).

`CSRF_COOKIE_PATH`

Default: `'/'`

The path set on the CSRF cookie. This should either match the URL path of your Django installation or be a parent of that path.

This is useful if you have multiple Django instances running under the same hostname. They can use different cookie paths, and each instance will only see its own CSRF cookie.

CSRF_COOKIE_SAMESITE

Default: 'Lax'

The value of the [SameSite](#) flag on the CSRF cookie. This flag prevents the cookie from being sent in cross-site requests.

See [SESSION_COOKIE_SAMESITE](#) for details about [SameSite](#).

CSRF_COOKIE_SECURE

Default: False

Whether to use a secure cookie for the CSRF cookie. If this is set to `True`, the cookie will be marked as “secure”, which means browsers may ensure that the cookie is only sent with an HTTPS connection.

CSRF_USE_SESSIONS

Default: False

Whether to store the CSRF token in the user’s session instead of in a cookie. It requires the use of [django.contrib.sessions](#).

Storing the CSRF token in a cookie (Django’s default) is safe, but storing it in the session is common practice in other web frameworks and therefore sometimes demanded by security auditors.

Since the [default error views](#) require the CSRF token, [SessionMiddleware](#) must appear in [MIDDLEWARE](#) before any middleware that may raise an exception to trigger an error view (such as [PermissionDenied](#)) if you’re using `CSRF_USE_SESSIONS`. See [Middleware ordering](#).

CSRF_FAILURE_VIEW

Default: 'django.views.csrf.csrf_failure'

A dotted path to the view function to be used when an incoming request is rejected by the [CSRF protection](#). The function should have this signature:

```
def csrf_failure(request, reason=""):
    ...
```

where `reason` is a short message (intended for developers or logging, not for end users) indicating the reason the request was rejected. It should return an [HttpResponseForbidden](#).

`django.views.csrf.csrf_failure()` accepts an additional `template_name` parameter that defaults to `'403_csrf.html'`. If a template with that name exists, it will be used to render the page.

CSRF_HEADER_NAME

Default: 'HTTP_X_CSRFTOKEN'

The name of the request header used for CSRF authentication.

As with other HTTP headers in `request.META`, the header name received from the server is normalized by converting all characters to uppercase, replacing any hyphens with underscores, and adding an 'HTTP_' prefix to the name. For example, if your client sends a 'X-XSRF-TOKEN' header, the setting should be 'HTTP_X_XSRF_TOKEN'.

CSRF_TRUSTED_ORIGINS

Default: [] (Empty list)

A list of trusted origins for unsafe requests (e.g. POST).

For requests that include the `Origin` header, Django's CSRF protection requires that header match the origin present in the `Host` header.

For a *secure* unsafe request that doesn't include the `Origin` header, the request must have a `Referer` header that matches the origin present in the `Host` header.

These checks prevent, for example, a POST request from `subdomain.example.com` from succeeding against `api.example.com`. If you need cross-origin unsafe requests, continuing the example, add '`https://subdomain.example.com`' to this list (and/or `http://...` if requests originate from an insecure page).

The setting also supports subdomains, so you could add '`https://*.example.com`', for example, to allow access from all subdomains of `example.com`.

DATABASES

Default: {} (Empty dictionary)

A dictionary containing the settings for all databases to be used with Django. It is a nested dictionary whose contents map a database alias to a dictionary containing the options for an individual database.

The `DATABASES` setting must configure a `default` database; any number of additional databases may also be specified.

The simplest possible settings file is for a single-database setup using SQLite. This can be configured using the following:

```
DATABASES = {
    "default": {
        "ENGINE": "django.db.backends.sqlite3",
        "NAME": "mydatabase",
```

(continues on next page)

(continued from previous page)

```
}  
}
```

When connecting to other database backends, such as MariaDB, MySQL, Oracle, or PostgreSQL, additional connection parameters will be required. See the [ENGINE](#) setting below on how to specify other database types. This example is for PostgreSQL:

```
DATABASES = {  
    "default": {  
        "ENGINE": "django.db.backends.postgresql",  
        "NAME": "mydatabase",  
        "USER": "mydatabaseuser",  
        "PASSWORD": "mypassword",  
        "HOST": "127.0.0.1",  
        "PORT": "5432",  
    }  
}
```

The following inner options that may be required for more complex configurations are available:

ATOMIC_REQUESTS

Default: `False`

Set this to `True` to wrap each view in a transaction on this database. See [Tying transactions to HTTP requests](#).

AUTOCOMMIT

Default: `True`

Set this to `False` if you want to [disable Django's transaction management](#) and implement your own.

ENGINE

Default: `''` (Empty string)

The database backend to use. The built-in database backends are:

- `'django.db.backends.postgresql'`
- `'django.db.backends.mysql'`
- `'django.db.backends.sqlite3'`

- `'django.db.backends.oracle'`

You can use a database backend that doesn't ship with Django by setting `ENGINE` to a fully-qualified path (i.e. `mypackage.backends.whatever`).

HOST

Default: `''` (Empty string)

Which host to use when connecting to the database. An empty string means localhost. Not used with SQLite.

If this value starts with a forward slash (`'/'`) and you're using MySQL, MySQL will connect via a Unix socket to the specified socket. For example:

```
"HOST": "/var/run/mysql"
```

If you're using MySQL and this value doesn't start with a forward slash, then this value is assumed to be the host.

If you're using PostgreSQL, by default (empty `HOST`), the connection to the database is done through UNIX domain sockets (`'local'` lines in `pg_hba.conf`). If your UNIX domain socket is not in the standard location, use the same value of `unix_socket_directory` from `postgresql.conf`. If you want to connect through TCP sockets, set `HOST` to `'localhost'` or `'127.0.0.1'` (`'host'` lines in `pg_hba.conf`). On Windows, you should always define `HOST`, as UNIX domain sockets are not available.

NAME

Default: `''` (Empty string)

The name of the database to use. For SQLite, it's the full path to the database file. When specifying the path, always use forward slashes, even on Windows (e.g. `C:/homes/user/mysite/sqlite3.db`).

CONN_MAX_AGE

Default: 0

The lifetime of a database connection, as an integer of seconds. Use 0 to close database connections at the end of each request —Django's historical behavior—and `None` for unlimited [persistent database connections](#).

CONN_HEALTH_CHECKS

Default: `False`

If set to `True`, existing [persistent database connections](#) will be health checked before they are reused in each request performing database access. If the health check fails, the connection will be reestablished without failing the request when the connection is no longer usable but the database server is ready to accept and serve new connections (e.g. after database server restart closing existing connections).

OPTIONS

Default: `{}` (Empty dictionary)

Extra parameters to use when connecting to the database. Available parameters vary depending on your database backend.

Some information on available parameters can be found in the [Database Backends](#) documentation. For more information, consult your backend module's own documentation.

PASSWORD

Default: `''` (Empty string)

The password to use when connecting to the database. Not used with SQLite.

PORT

Default: `''` (Empty string)

The port to use when connecting to the database. An empty string means the default port. Not used with SQLite.

TIME_ZONE

Default: `None`

A string representing the time zone for this database connection or `None`. This inner option of the [DATABASES](#) setting accepts the same values as the general [TIME_ZONE](#) setting.

When [USE_TZ](#) is `True` and this option is set, reading datetimes from the database returns aware datetimes in this time zone instead of UTC. When [USE_TZ](#) is `False`, it is an error to set this option.

- If the database backend doesn't support time zones (e.g. SQLite, MySQL, Oracle), Django reads and writes datetimes in local time according to this option if it is set and in UTC if it isn't.

Changing the connection time zone changes how datetimes are read from and written to the database.

- If Django manages the database and you don't have a strong reason to do otherwise, you should leave this option unset. It's best to store datetimes in UTC because it avoids ambiguous or nonexistent datetimes during daylight saving time changes. Also, receiving datetimes in UTC keeps datetime arithmetic simple —there's no need to consider potential offset changes over a DST transition.
- If you're connecting to a third-party database that stores datetimes in a local time rather than UTC, then you must set this option to the appropriate time zone. Likewise, if Django manages the database but third-party systems connect to the same database and expect to find datetimes in local time, then you must set this option.
- If the database backend supports time zones (e.g. PostgreSQL), the `TIME_ZONE` option is very rarely needed. It can be changed at any time; the database takes care of converting datetimes to the desired time zone.

Setting the time zone of the database connection may be useful for running raw SQL queries involving date/time functions provided by the database, such as `date_trunc`, because their results depend on the time zone.

However, this has a downside: receiving all datetimes in local time makes datetime arithmetic more tricky —you must account for possible offset changes over DST transitions.

Consider converting to local time explicitly with `AT TIME ZONE` in raw SQL queries instead of setting the `TIME_ZONE` option.

`DISABLE_SERVER_SIDE_CURSORS`

Default: `False`

Set this to `True` if you want to disable the use of server-side cursors with `QuerySet.iterator()`. [Transaction pooling and server-side cursors](#) describes the use case.

This is a PostgreSQL-specific setting.

`USER`

Default: `''` (Empty string)

The username to use when connecting to the database. Not used with SQLite.

TEST

Default: {} (Empty dictionary)

A dictionary of settings for test databases; for more details about the creation and use of test databases, see [The test database](#).

Here's an example with a test database configuration:

```
DATABASES = {
    "default": {
        "ENGINE": "django.db.backends.postgresql",
        "USER": "mydatabaseuser",
        "NAME": "mydatabase",
        "TEST": {
            "NAME": "mytestdatabase",
        },
    },
}
```

The following keys in the TEST dictionary are available:

CHARSET

Default: None

The character set encoding used to create the test database. The value of this string is passed directly through to the database, so its format is backend-specific.

Supported by the [PostgreSQL \(postgresql\)](#) and [MySQL \(mysql\)](#) backends.

COLLATION

Default: None

The collation order to use when creating the test database. This value is passed directly to the backend, so its format is backend-specific.

Only supported for the `mysql` backend (see the [MySQL manual](#) for details).

DEPENDENCIES

Default: `['default']`, for all databases other than `default`, which has no dependencies.

The creation-order dependencies of the database. See the documentation on [controlling the creation order of test databases](#) for details.

MIGRATE

Default: `True`

When set to `False`, migrations won't run when creating the test database. This is similar to setting `None` as a value in [MIGRATION_MODULES](#), but for all apps.

MIRROR

Default: `None`

The alias of the database that this database should mirror during testing. It depends on transactions and therefore must be used within [TransactionTestCase](#) instead of [TestCase](#).

This setting exists to allow for testing of primary/replica (referred to as master/slave by some databases) configurations of multiple databases. See the documentation on [testing primary/replica configurations](#) for details.

NAME

Default: `None`

The name of database to use when running the test suite.

If the default value (`None`) is used with the SQLite database engine, the tests will use a memory resident database. For all other database engines the test database will use the name `'test_' + DATABASE_NAME`.

See [The test database](#).

SERIALIZE

Boolean value to control whether or not the default test runner serializes the database into an in-memory JSON string before running tests (used to restore the database state between tests if you don't have transactions). You can set this to `False` to speed up creation time if you don't have any test classes with [serialized_rollback=True](#).

Deprecated since version 4.0: This setting is deprecated as it can be inferred from the [databases](#) with the [serialized_rollback](#) option enabled.

TEMPLATE

This is a PostgreSQL-specific setting.

The name of a `template` (e.g. `'template0'`) from which to create the test database.

CREATE_DB

Default: `True`

This is an Oracle-specific setting.

If it is set to `False`, the test tablespaces won't be automatically created at the beginning of the tests or dropped at the end.

CREATE_USER

Default: `True`

This is an Oracle-specific setting.

If it is set to `False`, the test user won't be automatically created at the beginning of the tests and dropped at the end.

USER

Default: `None`

This is an Oracle-specific setting.

The username to use when connecting to the Oracle database that will be used when running tests. If not provided, Django will use `'test_' + USER`.

PASSWORD

Default: `None`

This is an Oracle-specific setting.

The password to use when connecting to the Oracle database that will be used when running tests. If not provided, Django will generate a random password.

ORACLE_MANAGED_FILES

Default: `False`

This is an Oracle-specific setting.

If set to `True`, Oracle Managed Files (OMF) tablespaces will be used. `DATAFILE` and `DATAFILE_TMP` will be ignored.

TBLSPACE

Default: `None`

This is an Oracle-specific setting.

The name of the tablespace that will be used when running tests. If not provided, Django will use `'test_' + USER`.

TBLSPACE_TMP

Default: `None`

This is an Oracle-specific setting.

The name of the temporary tablespace that will be used when running tests. If not provided, Django will use `'test_' + USER + '_temp'`.

DATAFILE

Default: `None`

This is an Oracle-specific setting.

The name of the datafile to use for the TBLSPACE. If not provided, Django will use `TBLSPACE + '.dbf'`.

DATAFILE_TMP

Default: `None`

This is an Oracle-specific setting.

The name of the datafile to use for the TBLSPACE_TMP. If not provided, Django will use `TBLSPACE_TMP + '.dbf'`.

DATAFILE_MAXSIZE

Default: '500M'

This is an Oracle-specific setting.

The maximum size that the DATAFILE is allowed to grow to.

DATAFILE_TMP_MAXSIZE

Default: '500M'

This is an Oracle-specific setting.

The maximum size that the DATAFILE_TMP is allowed to grow to.

DATAFILE_SIZE

Default: '50M'

This is an Oracle-specific setting.

The initial size of the DATAFILE.

DATAFILE_TMP_SIZE

Default: '50M'

This is an Oracle-specific setting.

The initial size of the DATAFILE_TMP.

DATAFILE_EXTSIZE

Default: '25M'

This is an Oracle-specific setting.

The amount by which the DATAFILE is extended when more space is required.

DATAFILE_TMP_EXTSIZE

Default: '25M'

This is an Oracle-specific setting.

The amount by which the DATAFILE_TMP is extended when more space is required.

DATA_UPLOAD_MAX_MEMORY_SIZE

Default: 2621440 (i.e. 2.5 MB).

The maximum size in bytes that a request body may be before a *SuspiciousOperation* (`RequestDataTooBig`) is raised. The check is done when accessing `request.body` or `request.POST` and is calculated against the total request size excluding any file upload data. You can set this to `None` to disable the check. Applications that are expected to receive unusually large form posts should tune this setting.

The amount of request data is correlated to the amount of memory needed to process the request and populate the GET and POST dictionaries. Large requests could be used as a denial-of-service attack vector if left unchecked. Since web servers don't typically perform deep request inspection, it's not possible to perform a similar check at that level.

See also *FILE_UPLOAD_MAX_MEMORY_SIZE*.

DATA_UPLOAD_MAX_NUMBER_FIELDS

Default: 1000

The maximum number of parameters that may be received via GET or POST before a *SuspiciousOperation* (`TooManyFields`) is raised. You can set this to `None` to disable the check. Applications that are expected to receive an unusually large number of form fields should tune this setting.

The number of request parameters is correlated to the amount of time needed to process the request and populate the GET and POST dictionaries. Large requests could be used as a denial-of-service attack vector if left unchecked. Since web servers don't typically perform deep request inspection, it's not possible to perform a similar check at that level.

DATA_UPLOAD_MAX_NUMBER_FILES

Default: 100

The maximum number of files that may be received via POST in a multipart/form-data encoded request before a *SuspiciousOperation* (TooManyFiles) is raised. You can set this to `None` to disable the check. Applications that are expected to receive an unusually large number of file fields should tune this setting.

The number of accepted files is correlated to the amount of time and memory needed to process the request. Large requests could be used as a denial-of-service attack vector if left unchecked. Since web servers don't typically perform deep request inspection, it's not possible to perform a similar check at that level.

DATABASE_ROUTERS

Default: [] (Empty list)

The list of routers that will be used to determine which database to use when performing a database query.

See the documentation on [automatic database routing in multi database configurations](#).

DATE_FORMAT

Default: 'N j, Y' (e.g. Feb. 4, 2003)

The default formatting to use for displaying date fields in any part of the system. Note that if *USE_L10N* is set to `True`, then the locale-dictated format has higher precedence and will be applied instead. See *allowed date format strings*.

See also *DATETIME_FORMAT*, *TIME_FORMAT* and *SHORT_DATE_FORMAT*.

DATE_INPUT_FORMATS

Default:

```
[
    "%Y-%m-%d", # '2006-10-25'
    "%m/%d/%Y", # '10/25/2006'
    "%m/%d/%y", # '10/25/06'
    "%b %d %Y", # 'Oct 25 2006'
    "%b %d, %Y", # 'Oct 25, 2006'
    "%d %b %Y", # '25 Oct 2006'
    "%d %b, %Y", # '25 Oct, 2006'
    "%B %d %Y", # 'October 25 2006'
    "%B %d, %Y", # 'October 25, 2006'
    "%d %B %Y", # '25 October 2006'
```

(continues on next page)

(continued from previous page)

```
"%d %B, %Y", # '25 October, 2006'
]
```

A list of formats that will be accepted when inputting data on a date field. Formats will be tried in order, using the first valid one. Note that these format strings use Python's `datetime module syntax`, not the format strings from the `date` template filter.

When `USE_L10N` is `True`, the locale-dictated format has higher precedence and will be applied instead.

See also `DATETIME_INPUT_FORMATS` and `TIME_INPUT_FORMATS`.

DATETIME_FORMAT

Default: `'N j, Y, P'` (e.g. Feb. 4, 2003, 4 p.m.)

The default formatting to use for displaying datetime fields in any part of the system. Note that if `USE_L10N` is set to `True`, then the locale-dictated format has higher precedence and will be applied instead. See *allowed date format strings*.

See also `DATE_FORMAT`, `TIME_FORMAT` and `SHORT_DATETIME_FORMAT`.

DATETIME_INPUT_FORMATS

Default:

```
[
    "%Y-%m-%d %H:%M:%S", # '2006-10-25 14:30:59'
    "%Y-%m-%d %H:%M:%S.%f", # '2006-10-25 14:30:59.000200'
    "%Y-%m-%d %H:%M", # '2006-10-25 14:30'
    "%m/%d/%Y %H:%M:%S", # '10/25/2006 14:30:59'
    "%m/%d/%Y %H:%M:%S.%f", # '10/25/2006 14:30:59.000200'
    "%m/%d/%Y %H:%M", # '10/25/2006 14:30'
    "%m/%d/%y %H:%M:%S", # '10/25/06 14:30:59'
    "%m/%d/%y %H:%M:%S.%f", # '10/25/06 14:30:59.000200'
    "%m/%d/%y %H:%M", # '10/25/06 14:30'
]
```

A list of formats that will be accepted when inputting data on a datetime field. Formats will be tried in order, using the first valid one. Note that these format strings use Python's `datetime module syntax`, not the format strings from the `date` template filter. Date-only formats are not included as datetime fields will automatically try `DATE_INPUT_FORMATS` in last resort.

When `USE_L10N` is `True`, the locale-dictated format has higher precedence and will be applied instead.

See also `DATE_INPUT_FORMATS` and `TIME_INPUT_FORMATS`.

DEBUG

Default: `False`

A boolean that turns on/off debug mode.

Never deploy a site into production with `DEBUG` turned on.

One of the main features of debug mode is the display of detailed error pages. If your app raises an exception when `DEBUG` is `True`, Django will display a detailed traceback, including a lot of metadata about your environment, such as all the currently defined Django settings (from `settings.py`).

As a security measure, Django will not include settings that might be sensitive, such as `SECRET_KEY`. Specifically, it will exclude any setting whose name includes any of the following:

- `'API'`
- `'KEY'`
- `'PASS'`
- `'SECRET'`
- `'SIGNATURE'`
- `'TOKEN'`

Note that these are partial matches. `'PASS'` will also match `PASSWORD`, just as `'TOKEN'` will also match `TOKENIZED` and so on.

Still, note that there are always going to be sections of your debug output that are inappropriate for public consumption. File paths, configuration options and the like all give attackers extra information about your server.

It is also important to remember that when running with `DEBUG` turned on, Django will remember every SQL query it executes. This is useful when you're debugging, but it'll rapidly consume memory on a production server.

Finally, if `DEBUG` is `False`, you also need to properly set the `ALLOWED_HOSTS` setting. Failing to do so will result in all requests being returned as “Bad Request (400)” .

Note: The default `settings.py` file created by `django-admin startproject` sets `DEBUG = True` for convenience.

DEBUG_PROPAGATE_EXCEPTIONS

Default: `False`

If set to `True`, Django's exception handling of view functions (*handler500*, or the debug view if *DEBUG* is `True`) and logging of 500 responses (*django.request*) is skipped and exceptions propagate upward.

This can be useful for some test setups. It shouldn't be used on a live site unless you want your web server (instead of Django) to generate "Internal Server Error" responses. In that case, make sure your server doesn't show the stack trace or other sensitive information in the response.

DECIMAL_SEPARATOR

Default: `'.'` (Dot)

Default decimal separator used when formatting decimal numbers.

Note that if *USE_L10N* is set to `True`, then the locale-dictated format has higher precedence and will be applied instead.

See also *NUMBER_GROUPING*, *THOUSAND_SEPARATOR* and *USE_THOUSAND_SEPARATOR*.

DEFAULT_AUTO_FIELD

Default: `'django.db.models.AutoField'`

Default primary key field type to use for models that don't have a field with *primary_key=True*.

Migrating auto-created through tables

The value of *DEFAULT_AUTO_FIELD* will be respected when creating new auto-created through tables for many-to-many relationships.

Unfortunately, the primary keys of existing auto-created through tables cannot currently be updated by the migrations framework.

This means that if you switch the value of *DEFAULT_AUTO_FIELD* and then generate migrations, the primary keys of the related models will be updated, as will the foreign keys from the through table, but the primary key of the auto-created through table will not be migrated.

In order to address this, you should add a *RunSQL* operation to your migrations to perform the required `ALTER TABLE` step. You can check the existing table name through *sqlmigrate*, *dbshell*, or with the field's `remote_field.through._meta.db_table` property.

Explicitly defined through models are already handled by the migrations system.

Allowing automatic migrations for the primary key of existing auto-created through tables [may be implemented at a later date](#).

DEFAULT_CHARSET

Default: `'utf-8'`

Default charset to use for all `HttpResponse` objects, if a MIME type isn't manually specified. Used when constructing the `Content-Type` header.

DEFAULT_EXCEPTION_REPORTER

Default: `'django.views.debug.ExceptionReporter'`

Default exception reporter class to be used if none has been assigned to the `HttpRequest` instance yet. See [Custom error reports](#).

DEFAULT_EXCEPTION_REPORTER_FILTER

Default: `'django.views.debug.SafeExceptionReporterFilter'`

Default exception reporter filter class to be used if none has been assigned to the `HttpRequest` instance yet. See [Filtering error reports](#).

DEFAULT_FILE_STORAGE

Default: `'django.core.files.storage.FileSystemStorage'`

Default file storage class to be used for any file-related operations that don't specify a particular storage system. See [Managing files](#).

Deprecated since version 4.2: This setting is deprecated. Starting with Django 4.2, default file storage engine can be configured with the `STORAGES` setting under the `default` key.

DEFAULT_FROM_EMAIL

Default: `'webmaster@localhost'`

Default email address to use for various automated correspondence from the site manager(s). This doesn't include error messages sent to `ADMINS` and `MANAGERS`; for that, see [SERVER_EMAIL](#).

DEFAULT_INDEX_TABLESPACE

Default: '' (Empty string)

Default tablespace to use for indexes on fields that don't specify one, if the backend supports it (see [Tablespaces](#)).

DEFAULT_TABLESPACE

Default: '' (Empty string)

Default tablespace to use for models that don't specify one, if the backend supports it (see [Tablespaces](#)).

DISALLOWED_USER_AGENTS

Default: [] (Empty list)

List of compiled regular expression objects representing User-Agent strings that are not allowed to visit any page, systemwide. Use this for bots/crawlers. This is only used if `CommonMiddleware` is installed (see [Middleware](#)).

EMAIL_BACKEND

Default: `'django.core.mail.backends.smtp.EmailBackend'`

The backend to use for sending emails. For the list of available backends see [Sending email](#).

EMAIL_FILE_PATH

Default: Not defined

The directory used by the [file email backend](#) to store output files.

EMAIL_HOST

Default: `'localhost'`

The host to use for sending email.

See also [EMAIL_PORT](#).

EMAIL_HOST_PASSWORD

Default: '' (Empty string)

Password to use for the SMTP server defined in [EMAIL_HOST](#). This setting is used in conjunction with [EMAIL_HOST_USER](#) when authenticating to the SMTP server. If either of these settings is empty, Django won't attempt authentication.

See also [EMAIL_HOST_USER](#).

EMAIL_HOST_USER

Default: '' (Empty string)

Username to use for the SMTP server defined in [EMAIL_HOST](#). If empty, Django won't attempt authentication.

See also [EMAIL_HOST_PASSWORD](#).

EMAIL_PORT

Default: 25

Port to use for the SMTP server defined in [EMAIL_HOST](#).

EMAIL_SUBJECT_PREFIX

Default: '[Django] '

Subject-line prefix for email messages sent with `django.core.mail.mail_admins` or `django.core.mail.mail_managers`. You'll probably want to include the trailing space.

EMAIL_USE_LOCALTIME

Default: `False`

Whether to send the SMTP `Date` header of email messages in the local time zone (`True`) or in UTC (`False`).

EMAIL_USE_TLS

Default: `False`

Whether to use a TLS (secure) connection when talking to the SMTP server. This is used for explicit TLS connections, generally on port 587. If you are experiencing hanging connections, see the implicit TLS setting [EMAIL_USE_SSL](#).

EMAIL_USE_SSL

Default: `False`

Whether to use an implicit TLS (secure) connection when talking to the SMTP server. In most email documentation this type of TLS connection is referred to as SSL. It is generally used on port 465. If you are experiencing problems, see the explicit TLS setting [EMAIL_USE_TLS](#).

Note that [EMAIL_USE_TLS](#)/[EMAIL_USE_SSL](#) are mutually exclusive, so only set one of those settings to `True`.

EMAIL_SSL_CERTFILE

Default: `None`

If [EMAIL_USE_SSL](#) or [EMAIL_USE_TLS](#) is `True`, you can optionally specify the path to a PEM-formatted certificate chain file to use for the SSL connection.

EMAIL_SSL_KEYFILE

Default: `None`

If [EMAIL_USE_SSL](#) or [EMAIL_USE_TLS](#) is `True`, you can optionally specify the path to a PEM-formatted private key file to use for the SSL connection.

Note that setting [EMAIL_SSL_CERTFILE](#) and [EMAIL_SSL_KEYFILE](#) doesn't result in any certificate checking. They're passed to the underlying SSL connection. Please refer to the documentation of Python's `ssl.wrap_socket()` function for details on how the certificate chain file and private key file are handled.

EMAIL_TIMEOUT

Default: `None`

Specifies a timeout in seconds for blocking operations like the connection attempt.

FILE_UPLOAD_HANDLERS

Default:

```
[
    "django.core.files.uploadhandler.MemoryFileUploadHandler",
    "django.core.files.uploadhandler.TemporaryFileUploadHandler",
]
```

A list of handlers to use for uploading. Changing this setting allows complete customization –even replacement– of Django's upload process.

See [Managing files](#) for details.

`FILE_UPLOAD_MAX_MEMORY_SIZE`

Default: 2621440 (i.e. 2.5 MB).

The maximum size (in bytes) that an upload will be before it gets streamed to the file system. See [Managing files](#) for details.

See also `DATA_UPLOAD_MAX_MEMORY_SIZE`.

`FILE_UPLOAD_DIRECTORY_PERMISSIONS`

Default: `None`

The numeric mode to apply to directories created in the process of uploading files.

This setting also determines the default permissions for collected static directories when using the `collectstatic` management command. See `collectstatic` for details on overriding it.

This value mirrors the functionality and caveats of the `FILE_UPLOAD_PERMISSIONS` setting.

`FILE_UPLOAD_PERMISSIONS`

Default: `0o644`

The numeric mode (i.e. `0o644`) to set newly uploaded files to. For more information about what these modes mean, see the documentation for `os.chmod()`.

If `None`, you'll get operating-system dependent behavior. On most platforms, temporary files will have a mode of `0o600`, and files saved from memory will be saved using the system's standard umask.

For security reasons, these permissions aren't applied to the temporary files that are stored in `FILE_UPLOAD_TEMP_DIR`.

This setting also determines the default permissions for collected static files when using the `collectstatic` management command. See `collectstatic` for details on overriding it.

Warning: Always prefix the mode with `0o`.

If you're not familiar with file modes, please note that the `0o` prefix is very important: it indicates an octal number, which is the way that modes must be specified. If you try to use `644`, you'll get totally incorrect behavior.

FILE_UPLOAD_TEMP_DIR

Default: `None`

The directory to store data to (typically files larger than `FILE_UPLOAD_MAX_MEMORY_SIZE`) temporarily while uploading files. If `None`, Django will use the standard temporary directory for the operating system. For example, this will default to `/tmp` on *nix-style operating systems.

See [Managing files](#) for details.

FIRST_DAY_OF_WEEK

Default: 0 (Sunday)

A number representing the first day of the week. This is especially useful when displaying a calendar. This value is only used when not using format internationalization, or when a format cannot be found for the current locale.

The value must be an integer from 0 to 6, where 0 means Sunday, 1 means Monday and so on.

FIXTURE_DIRS

Default: `[]` (Empty list)

List of directories searched for `fixture` files, in addition to the `fixtures` directory of each application, in search order.

Note that these paths should use Unix-style forward slashes, even on Windows.

See [Provide data with fixtures](#) and [Fixture loading](#).

FORCE_SCRIPT_NAME

Default: `None`

If not `None`, this will be used as the value of the `SCRIPT_NAME` environment variable in any HTTP request. This setting can be used to override the server-provided value of `SCRIPT_NAME`, which may be a rewritten version of the preferred value or not supplied at all. It is also used by `django.setup()` to set the URL resolver script prefix outside of the request/response cycle (e.g. in management commands and standalone scripts) to generate correct URLs when `SCRIPT_NAME` is not `/`.

FORM_RENDERER

Default: `'django.forms.renderers.DjangoTemplates'`

The class that renders forms and form widgets. It must implement [the low-level render API](#). Included form renderers are:

- `'django.forms.renderers.DjangoTemplates'`
- `'django.forms.renderers.Jinja2'`
- `'django.forms.renderers.TemplatesSetting'`

FORMAT_MODULE_PATH

Default: `None`

A full Python path to a Python package that contains custom format definitions for project locales. If not `None`, Django will check for a `formats.py` file, under the directory named as the current locale, and will use the formats defined in this file.

For example, if `FORMAT_MODULE_PATH` is set to `mysite.formats`, and current language is `en` (English), Django will expect a directory tree like:

```
mysite/
  formats/
    __init__.py
  en/
    __init__.py
    formats.py
```

You can also set this setting to a list of Python paths, for example:

```
FORMAT_MODULE_PATH = [
    "mysite.formats",
    "some_app.formats",
]
```

When Django searches for a certain format, it will go through all given Python paths until it finds a module that actually defines the given format. This means that formats defined in packages farther up in the list will take precedence over the same formats in packages farther down.

Available formats are:

- `DATE_FORMAT`
- `DATE_INPUT_FORMATS`
- `DATETIME_FORMAT`,

- *DATETIME_INPUT_FORMATS*
- *DECIMAL_SEPARATOR*
- *FIRST_DAY_OF_WEEK*
- *MONTH_DAY_FORMAT*
- *NUMBER_GROUPING*
- *SHORT_DATE_FORMAT*
- *SHORT_DATETIME_FORMAT*
- *THOUSAND_SEPARATOR*
- *TIME_FORMAT*
- *TIME_INPUT_FORMATS*
- *YEAR_MONTH_FORMAT*

IGNORABLE_404_URLS

Default: [] (Empty list)

List of compiled regular expression objects describing URLs that should be ignored when reporting HTTP 404 errors via email (see [How to manage error reporting](#)). Regular expressions are matched against *request's full paths* (including query string, if any). Use this if your site does not provide a commonly requested file such as `favicon.ico` or `robots.txt`.

This is only used if *BrokenLinkEmailsMiddleware* is enabled (see [Middleware](#)).

INSTALLED_APPS

Default: [] (Empty list)

A list of strings designating all applications that are enabled in this Django installation. Each string should be a dotted Python path to:

- an application configuration class (preferred), or
- a package containing an application.

[Learn more about application configurations.](#)

Use the application registry for introspection

Your code should never access *INSTALLED_APPS* directly. Use *django.apps.apps* instead.

Application names and labels must be unique in `INSTALLED_APPS`

Application *names* —the dotted Python path to the application package —must be unique. There is no way to include the same application twice, short of duplicating its code under another name.

Application *labels* —by default the final part of the name —must be unique too. For example, you can't include both `django.contrib.auth` and `myproject.auth`. However, you can relabel an application with a custom configuration that defines a different *label*.

These rules apply regardless of whether `INSTALLED_APPS` references application configuration classes or application packages.

When several applications provide different versions of the same resource (template, static file, management command, translation), the application listed first in `INSTALLED_APPS` has precedence.

INTERNAL_IPS

Default: `[]` (Empty list)

A list of IP addresses, as strings, that:

- Allow the `debug()` context processor to add some variables to the template context.
- Can use the `admindocs` bookmarklets even if not logged in as a staff user.
- Are marked as “internal” (as opposed to “EXTERNAL”) in `AdminEmailHandler` emails.

LANGUAGE_CODE

Default: `'en-us'`

A string representing the language code for this installation. This should be in standard [language ID format](#). For example, U.S. English is `"en-us"`. See also the [list of language identifiers](#) and [Internationalization and localization](#).

`USE_I18N` must be active for this setting to have any effect.

It serves two purposes:

- If the locale middleware isn't in use, it decides which translation is served to all users.
- If the locale middleware is active, it provides a fallback language in case the user's preferred language can't be determined or is not supported by the website. It also provides the fallback translation when a translation for a given literal doesn't exist for the user's preferred language.

See [How Django discovers language preference](#) for more details.

LANGUAGE_COOKIE_AGE

Default: `None` (expires at browser close)

The age of the language cookie, in seconds.

LANGUAGE_COOKIE_DOMAIN

Default: `None`

The domain to use for the language cookie. Set this to a string such as `"example.com"` for cross-domain cookies, or use `None` for a standard domain cookie.

Be cautious when updating this setting on a production site. If you update this setting to enable cross-domain cookies on a site that previously used standard domain cookies, existing user cookies that have the old domain will not be updated. This will result in site users being unable to switch the language as long as these cookies persist. The only safe and reliable option to perform the switch is to change the language cookie name permanently (via the [LANGUAGE_COOKIE_NAME](#) setting) and to add a middleware that copies the value from the old cookie to a new one and then deletes the old one.

LANGUAGE_COOKIE_HTTPONLY

Default: `False`

Whether to use `HttpOnly` flag on the language cookie. If this is set to `True`, client-side JavaScript will not be able to access the language cookie.

See [SESSION_COOKIE_HTTPONLY](#) for details on `HttpOnly`.

LANGUAGE_COOKIE_NAME

Default: `'django_language'`

The name of the cookie to use for the language cookie. This can be whatever you want (as long as it's different from the other cookie names in your application). See [Internationalization and localization](#).

LANGUAGE_COOKIE_PATH

Default: `'/'`

The path set on the language cookie. This should either match the URL path of your Django installation or be a parent of that path.

This is useful if you have multiple Django instances running under the same hostname. They can use different cookie paths and each instance will only see its own language cookie.

Be cautious when updating this setting on a production site. If you update this setting to use a deeper path than it previously used, existing user cookies that have the old path will not be updated. This will result in site users being unable to switch the language as long as these cookies persist. The only safe and reliable option to perform the switch is to change the language cookie name permanently (via the [LANGUAGE_COOKIE_NAME](#) setting), and to add a middleware that copies the value from the old cookie to a new one and then deletes the one.

LANGUAGE_COOKIE_SAMESITE

Default: `None`

The value of the `SameSite` flag on the language cookie. This flag prevents the cookie from being sent in cross-site requests.

See [SESSION_COOKIE_SAMESITE](#) for details about `SameSite`.

LANGUAGE_COOKIE_SECURE

Default: `False`

Whether to use a secure cookie for the language cookie. If this is set to `True`, the cookie will be marked as “secure” , which means browsers may ensure that the cookie is only sent under an HTTPS connection.

LANGUAGES

Default: A list of all available languages. This list is continually growing and including a copy here would inevitably become rapidly out of date. You can see the current list of translated languages by looking in [django/conf/global_settings.py](#).

The list is a list of two-tuples in the format `(language code, language name)` –for example, `('ja', 'Japanese')`. This specifies which languages are available for language selection. See [Internationalization and localization](#).

Generally, the default value should suffice. Only set this setting if you want to restrict language selection to a subset of the Django-provided languages.

If you define a custom [LANGUAGES](#) setting, you can mark the language names as translation strings using the [gettext_lazy\(\)](#) function.

Here’s a sample settings file:

```
from django.utils.translation import gettext_lazy as _

LANGUAGES = [
    ("de", _("German")),
```

(continues on next page)

(continued from previous page)

```
("en", _("English")),  
]
```

LANGUAGES_BIDI

Default: A list of all language codes that are written right-to-left. You can see the current list of these languages by looking in [django/conf/global_settings.py](#).

The list contains [language codes](#) for languages that are written right-to-left.

Generally, the default value should suffice. Only set this setting if you want to restrict language selection to a subset of the Django-provided languages. If you define a custom [LANGUAGES](#) setting, the list of bidirectional languages may contain language codes which are not enabled on a given site.

LOCALE_PATHS

Default: [] (Empty list)

A list of directories where Django looks for translation files. See [How Django discovers translations](#).

Example:

```
LOCALE_PATHS = [  
    "/home/www/project/common_files/locale",  
    "/var/local/translations/locale",  
]
```

Django will look within each of these paths for the `<locale_code>/LC_MESSAGES` directories containing the actual translation files.

LOGGING

Default: A logging configuration dictionary.

A data structure containing configuration information. When not-empty, the contents of this data structure will be passed as the argument to the configuration method described in [LOGGING_CONFIG](#).

Among other things, the default logging configuration passes HTTP 500 server errors to an email log handler when [DEBUG](#) is `False`. See also [Configuring logging](#).

You can see the default logging configuration by looking in [django/utils/log.py](#).

LOGGING_CONFIG

Default: `'logging.config.dictConfig'`

A path to a callable that will be used to configure logging in the Django project. Points at an instance of Python's `dictConfig` configuration method by default.

If you set `LOGGING_CONFIG` to `None`, the logging configuration process will be skipped.

MANAGERS

Default: `[]` (Empty list)

A list in the same format as `ADMINS` that specifies who should get broken link notifications when `BrokenLinkEmailsMiddleware` is enabled.

MEDIA_ROOT

Default: `''` (Empty string)

Absolute filesystem path to the directory that will hold user-uploaded files.

Example: `"/var/www/example.com/media/"`

See also `MEDIA_URL`.

Warning: `MEDIA_ROOT` and `STATIC_ROOT` must have different values. Before `STATIC_ROOT` was introduced, it was common to rely or fallback on `MEDIA_ROOT` to also serve static files; however, since this can have serious security implications, there is a validation check to prevent it.

MEDIA_URL

Default: `''` (Empty string)

URL that handles the media served from `MEDIA_ROOT`, used for managing stored files. It must end in a slash if set to a non-empty value. You will need to configure these files to be served in both development and production environments.

If you want to use `{{ MEDIA_URL }}` in your templates, add `'django.template.context_processors.media'` in the `'context_processors'` option of `TEMPLATES`.

Example: `"http://media.example.com/"`

Warning: There are security risks if you are accepting uploaded content from untrusted users! See the security guide’s topic on [User-uploaded content](#) for mitigation details.

Warning: `MEDIA_URL` and `STATIC_URL` must have different values. See `MEDIA_ROOT` for more details.

Note: If `MEDIA_URL` is a relative path, then it will be prefixed by the server-provided value of `SCRIPT_NAME` (or `/` if not set). This makes it easier to serve a Django application in a subpath without adding an extra configuration to the settings.

MIDDLEWARE

Default: `None`

A list of middleware to use. See [Middleware](#).

MIGRATION_MODULES

Default: `{}` (Empty dictionary)

A dictionary specifying the package where migration modules can be found on a per-app basis. The default value of this setting is an empty dictionary, but the default package name for migration modules is `migrations`.

Example:

```
{"blog": "blog.db_migrations"}
```

In this case, migrations pertaining to the `blog` app will be contained in the `blog.db_migrations` package.

If you provide the `app_label` argument, *makemigrations* will automatically create the package if it doesn’t already exist.

When you supply `None` as a value for an app, Django will consider the app as an app without migrations regardless of an existing `migrations` submodule. This can be used, for example, in a test settings file to skip migrations while testing (tables will still be created for the apps’ models). To disable migrations for all apps during tests, you can set the `MIGRATE` to `False` instead. If `MIGRATION_MODULES` is used in your general project settings, remember to use the *migrate* `--run-syncdb` option if you want to create tables for the app.

MONTH_DAY_FORMAT

Default: 'F j'

The default formatting to use for date fields on Django admin change-list pages –and, possibly, by other parts of the system –in cases when only the month and day are displayed.

For example, when a Django admin change-list page is being filtered by a date drilldown, the header for a given day displays the day and month. Different locales have different formats. For example, U.S. English would say “January 1,” whereas Spanish might say “1 Enero.”

Note that if `USE_L10N` is set to `True`, then the corresponding locale-dictated format has higher precedence and will be applied.

See *allowed date format strings*. See also `DATE_FORMAT`, `DATETIME_FORMAT`, `TIME_FORMAT` and `YEAR_MONTH_FORMAT`.

NUMBER_GROUPING

Default: 0

Number of digits grouped together on the integer part of a number.

Common use is to display a thousand separator. If this setting is 0, then no grouping will be applied to the number. If this setting is greater than 0, then `THOUSAND_SEPARATOR` will be used as the separator between those groups.

Some locales use non-uniform digit grouping, e.g. 10,00,00,000 in `en_IN`. For this case, you can provide a sequence with the number of digit group sizes to be applied. The first number defines the size of the group preceding the decimal delimiter, and each number that follows defines the size of preceding groups. If the sequence is terminated with `-1`, no further grouping is performed. If the sequence terminates with a 0, the last group size is used for the remainder of the number.

Example tuple for `en_IN`:

```
NUMBER_GROUPING = (3, 2, 0)
```

Note that if `USE_L10N` is set to `True`, then the locale-dictated format has higher precedence and will be applied instead.

See also `DECIMAL_SEPARATOR`, `THOUSAND_SEPARATOR` and `USE_THOUSAND_SEPARATOR`.

PREPEND_WWW

Default: `False`

Whether to prepend the “www.” subdomain to URLs that don’t have it. This is only used if *CommonMiddleware* is installed (see *Middleware*). See also *APPEND_SLASH*.

ROOT_URLCONF

Default: Not defined

A string representing the full Python import path to your root URLconf, for example “`mydjangoapps.urls`”. Can be overridden on a per-request basis by setting the attribute `urlconf` on the incoming `HttpRequest` object. See *How Django processes a request* for details.

SECRET_KEY

Default: ‘’ (Empty string)

A secret key for a particular Django installation. This is used to provide *cryptographic signing*, and should be set to a unique, unpredictable value.

django-admin startproject automatically adds a randomly-generated `SECRET_KEY` to each new project.

Uses of the key shouldn’t assume that it’s text or bytes. Every use should go through *force_str()* or *force_bytes()* to convert it to the desired type.

Django will refuse to start if *SECRET_KEY* is not set.

Warning: Keep this value secret.

Running Django with a known *SECRET_KEY* defeats many of Django’s security protections, and can lead to privilege escalation and remote code execution vulnerabilities.

The secret key is used for:

- All *sessions* if you are using any other session backend than `django.contrib.sessions.backends.cache`, or are using the default *get_session_auth_hash()*.
- All *messages* if you are using *CookieStorage* or *FallbackStorage*.
- All *PasswordResetView* tokens.
- Any usage of *cryptographic signing*, unless a different key is provided.

When a secret key is no longer set as *SECRET_KEY* or contained within *SECRET_KEY_FALLBACKS* all of the above will be invalidated. When rotating your secret key, you should move the old key to *SECRET_KEY_FALLBACKS* temporarily. Secret keys are not used for passwords of users and key rotation will not affect them.

Note: The default `settings.py` file created by `django-admin startproject` creates a unique `SECRET_KEY` for convenience.

`SECRET_KEY_FALLBACKS`

Default: `[]`

A list of fallback secret keys for a particular Django installation. These are used to allow rotation of the `SECRET_KEY`.

In order to rotate your secret keys, set a new `SECRET_KEY` and move the previous value to the beginning of `SECRET_KEY_FALLBACKS`. Then remove the old values from the end of the `SECRET_KEY_FALLBACKS` when you are ready to expire the sessions, password reset tokens, and so on, that make use of them.

Note: Signing operations are computationally expensive. Having multiple old key values in `SECRET_KEY_FALLBACKS` adds additional overhead to all checks that don't match an earlier key.

As such, fallback values should be removed after an appropriate period, allowing for key rotation.

Uses of the secret key values shouldn't assume that they are text or bytes. Every use should go through `force_str()` or `force_bytes()` to convert it to the desired type.

`SECURE_CONTENT_TYPE_NOSNIFF`

Default: `True`

If `True`, the `SecurityMiddleware` sets the `X-Content-Type-Options: nosniff` header on all responses that do not already have it.

`SECURE_CROSS_ORIGIN_OPENER_POLICY`

Default: `'same-origin'`

Unless set to `None`, the `SecurityMiddleware` sets the `Cross-Origin Opener Policy` header on all responses that do not already have it to the value provided.

SECURE_HSTS_INCLUDE_SUBDOMAINS

Default: `False`

If `True`, the *SecurityMiddleware* adds the `includeSubDomains` directive to the HTTP Strict Transport Security header. It has no effect unless *SECURE_HSTS_SECONDS* is set to a non-zero value.

Warning: Setting this incorrectly can irreversibly (for the value of *SECURE_HSTS_SECONDS*) break your site. Read the [HTTP Strict Transport Security](#) documentation first.

SECURE_HSTS_PRELOAD

Default: `False`

If `True`, the *SecurityMiddleware* adds the `preload` directive to the HTTP Strict Transport Security header. It has no effect unless *SECURE_HSTS_SECONDS* is set to a non-zero value.

SECURE_HSTS_SECONDS

Default: `0`

If set to a non-zero integer value, the *SecurityMiddleware* sets the HTTP Strict Transport Security header on all responses that do not already have it.

Warning: Setting this incorrectly can irreversibly (for some time) break your site. Read the [HTTP Strict Transport Security](#) documentation first.

SECURE_PROXY_SSL_HEADER

Default: `None`

A tuple representing an HTTP header/value combination that signifies a request is secure. This controls the behavior of the request object's `is_secure()` method.

By default, `is_secure()` determines if a request is secure by confirming that a requested URL uses `https://`. This method is important for Django's CSRF protection, and it may be used by your own code or third-party apps.

If your Django app is behind a proxy, though, the proxy may be “swallowing” whether the original request uses HTTPS or not. If there is a non-HTTPS connection between the proxy and Django then `is_secure()` would always return `False` –even for requests that were made via HTTPS by the end user. In contrast, if

there is an HTTPS connection between the proxy and Django then `is_secure()` would always return `True` –even for requests that were made originally via HTTP.

In this situation, configure your proxy to set a custom HTTP header that tells Django whether the request came in via HTTPS, and set `SECURE_PROXY_SSL_HEADER` so that Django knows what header to look for.

Set a tuple with two elements –the name of the header to look for and the required value. For example:

```
SECURE_PROXY_SSL_HEADER = ("HTTP_X_FORWARDED_PROTO", "https")
```

This tells Django to trust the `X-Forwarded-Proto` header that comes from our proxy and that the request is guaranteed to be secure (i.e., it originally came in via HTTPS) when:

- the header value is `'https'`, or
- its initial, leftmost value is `'https'` in the case of a comma-separated list of protocols (e.g. `'https, http, http'`).

Support for a comma-separated list of protocols in the header value was added.

You should only set this setting if you control your proxy or have some other guarantee that it sets/strips this header appropriately.

Note that the header needs to be in the format as used by `request.META` –all caps and likely starting with `HTTP_`. (Remember, Django automatically adds `'HTTP_'` to the start of x-header names before making the header available in `request.META`.)

Warning: Modifying this setting can compromise your site’s security. Ensure you fully understand your setup before changing it.

Make sure ALL of the following are true before setting this (assuming the values from the example above):

- Your Django app is behind a proxy.
- Your proxy strips the `X-Forwarded-Proto` header from all incoming requests, even when it contains a comma-separated list of protocols. In other words, if end users include that header in their requests, the proxy will discard it.
- Your proxy sets the `X-Forwarded-Proto` header and sends it to Django, but only for requests that originally come in via HTTPS.

If any of those are not true, you should keep this setting set to `None` and find another way of determining HTTPS, perhaps via custom middleware.

SECURE_REDIRECT_EXEMPT

Default: [] (Empty list)

If a URL path matches a regular expression in this list, the request will not be redirected to HTTPS. The *SecurityMiddleware* strips leading slashes from URL paths, so patterns shouldn't include them, e.g. `SECURE_REDIRECT_EXEMPT = [r'^no-ssl/$', ...]`. If *SECURE_SSL_REDIRECT* is `False`, this setting has no effect.

SECURE_REFERRER_POLICY

Default: 'same-origin'

If configured, the *SecurityMiddleware* sets the *Referrer Policy* header on all responses that do not already have it to the value provided.

SECURE_SSL_HOST

Default: None

If a string (e.g. `secure.example.com`), all SSL redirects will be directed to this host rather than the originally-requested host (e.g. `www.example.com`). If *SECURE_SSL_REDIRECT* is `False`, this setting has no effect.

SECURE_SSL_REDIRECT

Default: `False`

If `True`, the *SecurityMiddleware* redirects all non-HTTPS requests to HTTPS (except for those URLs matching a regular expression listed in *SECURE_REDIRECT_EXEMPT*).

Note: If turning this to `True` causes infinite redirects, it probably means your site is running behind a proxy and can't tell which requests are secure and which are not. Your proxy likely sets a header to indicate secure requests; you can correct the problem by finding out what that header is and configuring the *SECURE_PROXY_SSL_HEADER* setting accordingly.

SERIALIZATION_MODULES

Default: Not defined

A dictionary of modules containing serializer definitions (provided as strings), keyed by a string identifier for that serialization type. For example, to define a YAML serializer, use:

```
SERIALIZATION_MODULES = {"yaml": "path.to.yaml_serializer"}
```

SERVER_EMAIL

Default: 'root@localhost'

The email address that error messages come from, such as those sent to [ADMINS](#) and [MANAGERS](#).

Why are my emails sent from a different address?

This address is used only for error messages. It is not the address that regular email messages sent with `send_mail()` come from; for that, see [DEFAULT_FROM_EMAIL](#).

SHORT_DATE_FORMAT

Default: 'm/d/Y' (e.g. 12/31/2003)

An available formatting that can be used for displaying date fields on templates. Note that if [USE_L10N](#) is set to `True`, then the corresponding locale-dictated format has higher precedence and will be applied. See [allowed date format strings](#).

See also [DATE_FORMAT](#) and [SHORT_DATETIME_FORMAT](#).

SHORT_DATETIME_FORMAT

Default: 'm/d/Y P' (e.g. 12/31/2003 4 p.m.)

An available formatting that can be used for displaying datetime fields on templates. Note that if [USE_L10N](#) is set to `True`, then the corresponding locale-dictated format has higher precedence and will be applied. See [allowed date format strings](#).

See also [DATE_FORMAT](#) and [SHORT_DATE_FORMAT](#).

SIGNING_BACKEND

Default: `'django.core.signing.TimestampSigner'`

The backend used for signing cookies and other data.

See also the [Cryptographic signing](#) documentation.

SILENCED_SYSTEM_CHECKS

Default: `[]` (Empty list)

A list of identifiers of messages generated by the system check framework (i.e. `["models.W001"]`) that you wish to permanently acknowledge and ignore. Silenced checks will not be output to the console.

See also the [System check framework](#) documentation.

STORAGES

Default:

```
{
    "default": {
        "BACKEND": "django.core.files.storage.FileSystemStorage",
    },
    "staticfiles": {
        "BACKEND": "django.contrib.staticfiles.storage.StaticFilesStorage",
    },
}
```

A dictionary containing the settings for all storages to be used with Django. It is a nested dictionary whose contents map a storage alias to a dictionary containing the options for an individual storage.

Storages can have any alias you choose. However, there are two aliases with special significance:

- **default** for [managing files](#). `'django.core.files.storage.FileSystemStorage'` is the default storage engine.
- **staticfiles** for [managing static files](#). `'django.contrib.staticfiles.storage.StaticFilesStorage'` is the default storage engine.

The following is an example `settings.py` snippet defining a custom file storage called `example`:

```
STORAGES = {
    # ...
    "example": {
        "BACKEND": "django.core.files.storage.FileSystemStorage",
```

(continues on next page)

(continued from previous page)

```

    "OPTIONS": {
        "location": "/example",
        "base_url": "/example/",
    },
},
}

```

OPTIONS are passed to the BACKEND on initialization in ****kwargs**.

A ready-to-use instance of the storage backends can be retrieved from `django.core.files.storage.storages`. Use a key corresponding to the backend definition in *STORAGES*.

TEMPLATES

Default: [] (Empty list)

A list containing the settings for all template engines to be used with Django. Each item of the list is a dictionary containing the options for an individual engine.

Here's a setup that tells the Django template engine to load templates from the `templates` subdirectory inside each installed application:

```

TEMPLATES = [
    {
        "BACKEND": "django.template.backends.django.DjangoTemplates",
        "APP_DIRS": True,
    },
]

```

The following options are available for all backends.

BACKEND

Default: Not defined

The template backend to use. The built-in template backends are:

- `'django.template.backends.django.DjangoTemplates'`
- `'django.template.backends.jinja2.Jinja2'`

You can use a template backend that doesn't ship with Django by setting BACKEND to a fully-qualified path (i.e. `'mypackage.whatever.Backend'`).

NAME

Default: see below

The alias for this particular template engine. It's an identifier that allows selecting an engine for rendering. Aliases must be unique across all configured template engines.

It defaults to the name of the module defining the engine class, i.e. the next to last piece of `BACKEND`, when it isn't provided. For example if the backend is `'mypackage.whatever.Backend'` then its default name is `'whatever'`.

DIRS

Default: `[]` (Empty list)

Directories where the engine should look for template source files, in search order.

APP_DIRS

Default: `False`

Whether the engine should look for template source files inside installed applications.

Note: The default `settings.py` file created by `django-admin startproject` sets `'APP_DIRS': True`.

OPTIONS

Default: `{}` (Empty dict)

Extra parameters to pass to the template backend. Available parameters vary depending on the template backend. See *DjangoTemplates* and *Jinja2* for the options of the built-in backends.

TEST_RUNNER

Default: `'django.test.runner.DiscoverRunner'`

The name of the class to use for starting the test suite. See [Using different testing frameworks](#).

TEST_NON_SERIALIZED_APPS

Default: [] (Empty list)

In order to restore the database state between tests for `TransactionTestCase`s and database backends without transactions, Django will [serialize the contents of all apps](#) when it starts the test run so it can then reload from that copy before running tests that need it.

This slows down the startup time of the test runner; if you have apps that you know don't need this feature, you can add their full names in here (e.g. `'django.contrib.contenttypes'`) to exclude them from this serialization process.

THOUSAND_SEPARATOR

Default: ',' (Comma)

Default thousand separator used when formatting numbers. This setting is used only when [USE_THOUSAND_SEPARATOR](#) is `True` and [NUMBER_GROUPING](#) is greater than 0.

Note that if [USE_L10N](#) is set to `True`, then the locale-dictated format has higher precedence and will be applied instead.

See also [NUMBER_GROUPING](#), [DECIMAL_SEPARATOR](#) and [USE_THOUSAND_SEPARATOR](#).

TIME_FORMAT

Default: 'P' (e.g. 4 p.m.)

The default formatting to use for displaying time fields in any part of the system. Note that if [USE_L10N](#) is set to `True`, then the locale-dictated format has higher precedence and will be applied instead. See [allowed date format strings](#).

See also [DATE_FORMAT](#) and [DATETIME_FORMAT](#).

TIME_INPUT_FORMATS

Default:

```
[
    "%H:%M:%S", # '14:30:59'
    "%H:%M:%S.%f", # '14:30:59.000200'
    "%H:%M", # '14:30'
]
```

A list of formats that will be accepted when inputting data on a time field. Formats will be tried in order, using the first valid one. Note that these format strings use Python's [datetime module syntax](#), not the format strings from the [date](#) template filter.

When `USE_L10N` is `True`, the locale-dictated format has higher precedence and will be applied instead.

See also `DATE_INPUT_FORMATS` and `DATETIME_INPUT_FORMATS`.

`TIME_ZONE`

Default: `'America/Chicago'`

A string representing the time zone for this installation. See the [list of time zones](#).

Note: Since Django was first released with the `TIME_ZONE` set to `'America/Chicago'`, the global setting (used if nothing is defined in your project's `settings.py`) remains `'America/Chicago'` for backwards compatibility. New project templates default to `'UTC'`.

Note that this isn't necessarily the time zone of the server. For example, one server may serve multiple Django-powered sites, each with a separate time zone setting.

When `USE_TZ` is `False`, this is the time zone in which Django will store all datetimes. When `USE_TZ` is `True`, this is the default time zone that Django will use to display datetimes in templates and to interpret datetimes entered in forms.

On Unix environments (where `time.tzset()` is implemented), Django sets the `os.environ['TZ']` variable to the time zone you specify in the `TIME_ZONE` setting. Thus, all your views and models will automatically operate in this time zone. However, Django won't set the TZ environment variable if you're using the manual configuration option as described in [manually configuring settings](#). If Django doesn't set the TZ environment variable, it's up to you to ensure your processes are running in the correct environment.

Note: Django cannot reliably use alternate time zones in a Windows environment. If you're running Django on Windows, `TIME_ZONE` must be set to match the system time zone.

`USE_DEPRECATED_PYTZ`

Default: `False`

A boolean that specifies whether to use `pytz`, rather than `zoneinfo`, as the default time zone implementation.

Deprecated since version 4.0: This transitional setting is deprecated. Support for using `pytz` will be removed in Django 5.0.

USE_I18N

Default: `True`

A boolean that specifies whether Django’s translation system should be enabled. This provides a way to turn it off, for performance. If this is set to `False`, Django will make some optimizations so as not to load the translation machinery.

See also [LANGUAGE_CODE](#), [USE_L10N](#) and [USE_TZ](#).

Note: The default `settings.py` file created by *django-admin startproject* includes `USE_I18N = True` for convenience.

USE_L10N

Default: `True`

A boolean that specifies if localized formatting of data will be enabled by default or not. If this is set to `True`, e.g. Django will display numbers and dates using the format of the current locale.

See also [LANGUAGE_CODE](#), [USE_I18N](#) and [USE_TZ](#).

Deprecated since version 4.0: This setting is deprecated. Starting with Django 5.0, localized formatting of data will always be enabled. For example Django will display numbers and dates using the format of the current locale.

USE_THOUSAND_SEPARATOR

Default: `False`

A boolean that specifies whether to display numbers using a thousand separator. When set to `True` and [USE_L10N](#) is also `True`, Django will format numbers using the [NUMBER_GROUPING](#) and [THOUSAND_SEPARATOR](#) settings. The latter two settings may also be dictated by the locale, which takes precedence.

See also [DECIMAL_SEPARATOR](#), [NUMBER_GROUPING](#) and [THOUSAND_SEPARATOR](#).

USE_TZ

Default: `False`

Note: In Django 5.0, the default value will change from `False` to `True`.

A boolean that specifies if datetimes will be timezone-aware by default or not. If this is set to `True`, Django will use timezone-aware datetimes internally.

When `USE_TZ` is `False`, Django will use naive datetimes in local time, except when parsing ISO 8601 formatted strings, where timezone information will always be retained if present.

See also [`TIME\_ZONE`](#), [`USE\_I18N`](#) and [`USE\_L10N`](#).

Note: The default `settings.py` file created by `django-admin startproject` includes `USE_TZ = True` for convenience.

`USE_X_FORWARDED_HOST`

Default: `False`

A boolean that specifies whether to use the `X-Forwarded-Host` header in preference to the `Host` header. This should only be enabled if a proxy which sets this header is in use.

This setting takes priority over [`USE\_X\_FORWARDED\_PORT`](#). Per [RFC 7239#section-5.3](#), the `X-Forwarded-Host` header can include the port number, in which case you shouldn't use [`USE\_X\_FORWARDED\_PORT`](#).

`USE_X_FORWARDED_PORT`

Default: `False`

A boolean that specifies whether to use the `X-Forwarded-Port` header in preference to the `SERVER_PORT` META variable. This should only be enabled if a proxy which sets this header is in use.

[`USE\_X\_FORWARDED\_HOST`](#) takes priority over this setting.

`WSGI_APPLICATION`

Default: `None`

The full Python path of the WSGI application object that Django's built-in servers (e.g. [`runserver`](#)) will use. The `django-admin startproject` management command will create a standard `wsgi.py` file with an application callable in it, and point this setting to that application.

If not set, the return value of `django.core.wsgi.get_wsgi_application()` will be used. In this case, the behavior of [`runserver`](#) will be identical to previous Django versions.

YEAR_MONTH_FORMAT

Default: 'F Y'

The default formatting to use for date fields on Django admin change-list pages –and, possibly, by other parts of the system –in cases when only the year and month are displayed.

For example, when a Django admin change-list page is being filtered by a date drilldown, the header for a given month displays the month and the year. Different locales have different formats. For example, U.S. English would say “January 2006,” whereas another locale might say “2006/January.”

Note that if `USE_L10N` is set to `True`, then the corresponding locale-dictated format has higher precedence and will be applied.

See *allowed date format strings*. See also `DATE_FORMAT`, `DATETIME_FORMAT`, `TIME_FORMAT` and `MONTH_DAY_FORMAT`.

X_FRAME_OPTIONS

Default: 'DENY'

The default value for the X-Frame-Options header used by `XFrameOptionsMiddleware`. See the [clickjacking protection](#) documentation.

6.20.2 Auth

Settings for `django.contrib.auth`.

AUTHENTICATION_BACKENDS

Default: `['django.contrib.auth.backends.ModelBackend']`

A list of authentication backend classes (as strings) to use when attempting to authenticate a user. See the [authentication backends](#) documentation for details.

AUTH_USER_MODEL

Default: `'auth.User'`

The model to use to represent a User. See [Substituting a custom User model](#).

Warning: You cannot change the `AUTH_USER_MODEL` setting during the lifetime of a project (i.e. once you have made and migrated models that depend on it) without serious effort. It is intended to be

set at the project start, and the model it refers to must be available in the first migration of the app that it lives in. See [Substituting a custom User model](#) for more details.

LOGIN_REDIRECT_URL

Default: `'/accounts/profile/'`

The URL or [named URL pattern](#) where requests are redirected after login when the *LoginView* doesn't get a next GET parameter.

LOGIN_URL

Default: `'/accounts/login/'`

The URL or [named URL pattern](#) where requests are redirected for login when using the *login_required()* decorator, *LoginRequiredMixin*, or *AccessMixin*.

LOGOUT_REDIRECT_URL

Default: `None`

The URL or [named URL pattern](#) where requests are redirected after logout if *LogoutView* doesn't have a `next_page` attribute.

If `None`, no redirect will be performed and the logout view will be rendered.

PASSWORD_RESET_TIMEOUT

Default: `259200` (3 days, in seconds)

The number of seconds a password reset link is valid for.

Used by the *PasswordResetConfirmView*.

Note: Reducing the value of this timeout doesn't make any difference to the ability of an attacker to brute-force a password reset token. Tokens are designed to be safe from brute-forcing without any timeout.

This timeout exists to protect against some unlikely attack scenarios, such as someone gaining access to email archives that may contain old, unused password reset tokens.

PASSWORD_HASHERS

See [How Django stores passwords](#).

Default:

```
[
    "django.contrib.auth.hashers.PBKDF2PasswordHasher",
    "django.contrib.auth.hashers.PBKDF2SHA1PasswordHasher",
    "django.contrib.auth.hashers.Argon2PasswordHasher",
    "django.contrib.auth.hashers.BCryptSHA256PasswordHasher",
]
```

AUTH_PASSWORD_VALIDATORS

Default: `[]` (Empty list)

The list of validators that are used to check the strength of user's passwords. See [Password validation](#) for more details. By default, no validation is performed and all passwords are accepted.

6.20.3 Messages

Settings for *django.contrib.messages*.

MESSAGE_LEVEL

Default: `messages.INFO`

Sets the minimum message level that will be recorded by the messages framework. See [message levels](#) for more details.

Avoiding circular imports

If you override `MESSAGE_LEVEL` in your settings file and rely on any of the built-in constants, you must import the constants module directly to avoid the potential for circular imports, e.g.:

```
from django.contrib.messages import constants as message_constants

MESSAGE_LEVEL = message_constants.DEBUG
```

If desired, you may specify the numeric values for the constants directly according to the values in the [above constants table](#).

MESSAGE_STORAGE

Default: `'django.contrib.messages.storage.fallback.FallbackStorage'`

Controls where Django stores message data. Valid values are:

- `'django.contrib.messages.storage.fallback.FallbackStorage'`
- `'django.contrib.messages.storage.session.SessionStorage'`
- `'django.contrib.messages.storage.cookie.CookieStorage'`

See [message storage backends](#) for more details.

The backends that use cookies –*CookieStorage* and *FallbackStorage* –use the value of *SESSION_COOKIE_DOMAIN*, *SESSION_COOKIE_SECURE* and *SESSION_COOKIE_HTTPONLY* when setting their cookies.

MESSAGE_TAGS

Default:

```
{
    messages.DEBUG: "debug",
    messages.INFO: "info",
    messages.SUCCESS: "success",
    messages.WARNING: "warning",
    messages.ERROR: "error",
}
```

This sets the mapping of message level to message tag, which is typically rendered as a CSS class in HTML. If you specify a value, it will extend the default. This means you only have to specify those values which you need to override. See [Displaying messages](#) above for more details.

Avoiding circular imports

If you override `MESSAGE_TAGS` in your settings file and rely on any of the built-in constants, you must import the `constants` module directly to avoid the potential for circular imports, e.g.:

```
from django.contrib.messages import constants as message_constants

MESSAGE_TAGS = {message_constants.INFO: ""}
```

If desired, you may specify the numeric values for the constants directly according to the values in the above [constants table](#).

6.20.4 Sessions

Settings for *django.contrib.sessions*.

SESSION_CACHE_ALIAS

Default: 'default'

If you're using [cache-based session storage](#), this selects the cache to use.

SESSION_COOKIE_AGE

Default: 1209600 (2 weeks, in seconds)

The age of session cookies, in seconds.

SESSION_COOKIE_DOMAIN

Default: None

The domain to use for session cookies. Set this to a string such as "example.com" for cross-domain cookies, or use None for a standard domain cookie.

To use cross-domain cookies with [CSRF_USE_SESSIONS](#), you must include a leading dot (e.g. ".example.com") to accommodate the CSRF middleware's referer checking.

Be cautious when updating this setting on a production site. If you update this setting to enable cross-domain cookies on a site that previously used standard domain cookies, existing user cookies will be set to the old domain. This may result in them being unable to log in as long as these cookies persist.

This setting also affects cookies set by *django.contrib.messages*.

SESSION_COOKIE_HTTPONLY

Default: True

Whether to use `HttpOnly` flag on the session cookie. If this is set to `True`, client-side JavaScript will not be able to access the session cookie.

`HttpOnly` is a flag included in a `Set-Cookie` HTTP response header. It's part of the [RFC 6265#section-4.1.2.6](#) standard for cookies and can be a useful way to mitigate the risk of a client-side script accessing the protected cookie data.

This makes it less trivial for an attacker to escalate a cross-site scripting vulnerability into full hijacking of a user's session. There aren't many good reasons for turning this off. Your code shouldn't read session cookies from JavaScript.

SESSION_COOKIE_NAME

Default: `'sessionid'`

The name of the cookie to use for sessions. This can be whatever you want (as long as it's different from the other cookie names in your application).

SESSION_COOKIE_PATH

Default: `'/'`

The path set on the session cookie. This should either match the URL path of your Django installation or be parent of that path.

This is useful if you have multiple Django instances running under the same hostname. They can use different cookie paths, and each instance will only see its own session cookie.

SESSION_COOKIE_SAMESITE

Default: `'Lax'`

The value of the `SameSite` flag on the session cookie. This flag prevents the cookie from being sent in cross-site requests thus preventing CSRF attacks and making some methods of stealing session cookie impossible.

Possible values for the setting are:

- `'Strict'`: prevents the cookie from being sent by the browser to the target site in all cross-site browsing context, even when following a regular link.

For example, for a GitHub-like website this would mean that if a logged-in user follows a link to a private GitHub project posted on a corporate discussion forum or email, GitHub will not receive the session cookie and the user won't be able to access the project. A bank website, however, most likely doesn't want to allow any transactional pages to be linked from external sites so the `'Strict'` flag would be appropriate.

- `'Lax'` (default): provides a balance between security and usability for websites that want to maintain user's logged-in session after the user arrives from an external link.

In the GitHub scenario, the session cookie would be allowed when following a regular link from an external website and be blocked in CSRF-prone request methods (e.g. `POST`).

- `'None'` (string): the session cookie will be sent with all same-site and cross-site requests.
- `False`: disables the flag.

Note: Modern browsers provide a more secure default policy for the `SameSite` flag and will assume `Lax` for cookies without an explicit value set.

SESSION_COOKIE_SECURE

Default: `False`

Whether to use a secure cookie for the session cookie. If this is set to `True`, the cookie will be marked as “secure”, which means browsers may ensure that the cookie is only sent under an HTTPS connection.

Leaving this setting off isn’t a good idea because an attacker could capture an unencrypted session cookie with a packet sniffer and use the cookie to hijack the user’s session.

SESSION_ENGINE

Default: `'django.contrib.sessions.backends.db'`

Controls where Django stores session data. Included engines are:

- `'django.contrib.sessions.backends.db'`
- `'django.contrib.sessions.backends.file'`
- `'django.contrib.sessions.backends.cache'`
- `'django.contrib.sessions.backends.cached_db'`
- `'django.contrib.sessions.backends.signed_cookies'`

See [Configuring the session engine](#) for more details.

SESSION_EXPIRE_AT_BROWSER_CLOSE

Default: `False`

Whether to expire the session when the user closes their browser. See [Browser-length sessions vs. persistent sessions](#).

SESSION_FILE_PATH

Default: `None`

If you’re using file-based session storage, this sets the directory in which Django will store session data. When the default value (`None`) is used, Django will use the standard temporary directory for the system.

SESSION_SAVE_EVERY_REQUEST

Default: `False`

Whether to save the session data on every request. If this is `False` (default), then the session data will only be saved if it has been modified—that is, if any of its dictionary values have been assigned or deleted. Empty sessions won't be created, even if this setting is active.

SESSION_SERIALIZER

Default: `'django.contrib.sessions.serializers.JSONSerializer'`

Full import path of a serializer class to use for serializing session data. Included serializer is:

- `'django.contrib.sessions.serializers.JSONSerializer'`

See [Session serialization](#) for details.

6.20.5 Sites

Settings for *`django.contrib.sites`*.

SITE_ID

Default: Not defined

The ID, as an integer, of the current site in the `django_site` database table. This is used so that application data can hook into specific sites and a single database can manage content for multiple sites.

6.20.6 Static Files

Settings for *`django.contrib.staticfiles`*.

STATIC_ROOT

Default: `None`

The absolute path to the directory where *`collectstatic`* will collect static files for deployment.

Example: `"/var/www/example.com/static/"`

If the *`staticfiles`* contrib app is enabled (as in the default project template), the *`collectstatic`* management command will collect static files into this directory. See the how-to on [managing static files](#) for more details about usage.

Warning: This should be an initially empty destination directory for collecting your static files from their permanent locations into one directory for ease of deployment; it is not a place to store your static files permanently. You should do that in directories that will be found by `staticfiles`'s *finders*, which by default, are `'static/'` app sub-directories and any directories you include in `STATICFILES_DIRS`.

STATIC_URL

Default: `None`

URL to use when referring to static files located in `STATIC_ROOT`.

Example: `"static/"` or `"http://static.example.com/"`

If not `None`, this will be used as the base path for `asset definitions` (the `Media` class) and the `staticfiles` app.

It must end in a slash if set to a non-empty value.

You may need to [configure these files to be served in development](#) and will definitely need to do so [in production](#).

Note: If `STATIC_URL` is a relative path, then it will be prefixed by the server-provided value of `SCRIPT_NAME` (or `/` if not set). This makes it easier to serve a Django application in a subpath without adding an extra configuration to the settings.

STATICFILES_DIRS

Default: `[]` (Empty list)

This setting defines the additional locations the `staticfiles` app will traverse if the `FileSystemFinder` finder is enabled, e.g. if you use the `collectstatic` or `findstatic` management command or use the static file serving view.

This should be set to a list of strings that contain full paths to your additional files directory(ies) e.g.:

```
STATICFILES_DIRS = [  
    "/home/special.polls.com/polls/static",  
    "/home/polls.com/polls/static",  
    "/opt/webfiles/common",  
]
```

Note that these paths should use Unix-style forward slashes, even on Windows (e.g. `"C:/Users/user/mysite/extra_static_content"`).

Prefixes (optional)

In case you want to refer to files in one of the locations with an additional namespace, you can optionally provide a prefix as (prefix, path) tuples, e.g.:

```
STATICFILES_DIRS = [
    # ...
    ("downloads", "/opt/webfiles/stats"),
]
```

For example, assuming you have `STATIC_URL` set to `'static/'`, the `collectstatic` management command would collect the “stats” files in a `'downloads'` subdirectory of `STATIC_ROOT`.

This would allow you to refer to the local file `'/opt/webfiles/stats/polls_20101022.tar.gz'` with `'/static/downloads/polls_20101022.tar.gz'` in your templates, e.g.:

```
<a href="{% static 'downloads/polls_20101022.tar.gz' %}">
```

STATICFILES_STORAGE

Default: `'django.contrib.staticfiles.storage.StaticFilesStorage'`

The file storage engine to use when collecting static files with the `collectstatic` management command.

A ready-to-use instance of the storage backend defined in this setting can be found under `staticfiles` key in `django.core.files.storage.storages`.

For an example, see [Serving static files from a cloud service or CDN](#).

Deprecated since version 4.2: This setting is deprecated. Starting with Django 4.2, static files storage engine can be configured with the `STORAGES` setting under the `staticfiles` key.

STATICFILES_FINDERS

Default:

```
[
    "django.contrib.staticfiles.finders.FileSystemFinder",
    "django.contrib.staticfiles.finders.AppDirectoriesFinder",
]
```

The list of finder backends that know how to find static files in various locations.

The default will find files stored in the `STATICFILES_DIRS` setting (using `django.contrib.staticfiles.finders.FileSystemFinder`) and in a `static` subdirectory of each app (using `django.contrib`.

`staticfiles.finders.AppDirectoriesFinder`). If multiple files with the same name are present, the first file that is found will be used.

One finder is disabled by default: `django.contrib.staticfiles.finders.DefaultStorageFinder`. If added to your `STATICFILES_FINDERS` setting, it will look for static files in the default file storage as defined by the default key in the `STORAGES` setting.

Note: When using the `AppDirectoriesFinder` finder, make sure your apps can be found by staticfiles by adding the app to the `INSTALLED_APPS` setting of your site.

Static file finders are currently considered a private interface, and this interface is thus undocumented.

6.20.7 Core Settings Topical Index

Cache

- `CACHES`
- `CACHE_MIDDLEWARE_ALIAS`
- `CACHE_MIDDLEWARE_KEY_PREFIX`
- `CACHE_MIDDLEWARE_SECONDS`

Database

- `DATABASES`
- `DATABASE_ROUTERS`
- `DEFAULT_INDEX_TABLESPACE`

6.21 Signals

A list of all the signals that Django sends. All built-in signals are sent using the *send()* method.

See also:

See the documentation on the [signal dispatcher](#) for information regarding how to register for and receive signals.

The [authentication framework](#) sends signals when a user is logged in / out.

6.21.1 Model signals

The `django.db.models.signals` module defines a set of signals sent by the model system.

Warning: Signals can make your code harder to maintain. Consider implementing a helper method on a [custom manager](#), to both update your models and perform additional logic, or else [overriding model methods](#) before using model signals.

Warning: Many of these signals are sent by various model methods like `__init__()` or `save()` that you can override in your own code.

If you override these methods on your model, you must call the parent class' methods for these signals to be sent.

Note also that Django stores signal handlers as weak references by default, so if your handler is a local function, it may be garbage collected. To prevent this, pass `weak=False` when you call the signal' s `connect()`.

Note: Model signals `sender` model can be lazily referenced when connecting a receiver by specifying its full application label. For example, an `Question` model defined in the `polls` application could be referenced as `'polls.Question'`. This sort of reference can be quite handy when dealing with circular import dependencies and swappable models.

`pre_init`

`django.db.models.signals.pre_init`

Whenever you instantiate a Django model, this signal is sent at the beginning of the model' s `__init__()` method.

Arguments sent with this signal:

sender

The model class that just had an instance created.

args

A list of positional arguments passed to `__init__()`.

kwargs

A dictionary of keyword arguments passed to `__init__()`.

For example, the [tutorial](#) has this line:

```
q = Question(question_text="What's new?", pub_date=timezone.now())
```

The arguments sent to a *pre_init* handler would be:

Argument	Value
sender	Question (the class itself)
args	[] (an empty list because there were no positional arguments passed to <code>__init__()</code>)
kwargs	{'question_text': 'What's new?', 'pub_date': datetime.datetime(2012, 2, 26, 13, 0, 0, 775217, tzinfo=datetime.timezone.utc)}

post_init

`django.db.models.signals.post_init`

Like *pre_init*, but this one is sent when the `__init__()` method finishes.

Arguments sent with this signal:

sender

As above: the model class that just had an instance created.

instance

The actual instance of the model that's just been created.

Note: *instance._state* isn't set before sending the *post_init* signal, so *_state* attributes always have their default values. For example, *_state.db* is *None*.

Warning: For performance reasons, you shouldn't perform queries in receivers of *pre_init* or *post_init* signals because they would be executed for each instance returned during queryset iteration.

pre_save

`django.db.models.signals.pre_save`

This is sent at the beginning of a model's *save()* method.

Arguments sent with this signal:

sender

The model class.

instance

The actual instance being saved.

raw

A boolean; `True` if the model is saved exactly as presented (i.e. when loading a [fixture](#)). One should not query/modify other records in the database as the database might not be in a consistent state yet.

using

The database alias being used.

update_fields

The set of fields to update as passed to `Model.save()`, or `None` if `update_fields` wasn't passed to `save()`.

post_save

`django.db.models.signals.post_save`

Like [pre_save](#), but sent at the end of the `save()` method.

Arguments sent with this signal:

sender

The model class.

instance

The actual instance being saved.

created

A boolean; `True` if a new record was created.

raw

A boolean; `True` if the model is saved exactly as presented (i.e. when loading a [fixture](#)). One should not query/modify other records in the database as the database might not be in a consistent state yet.

using

The database alias being used.

update_fields

The set of fields to update as passed to `Model.save()`, or `None` if `update_fields` wasn't passed to `save()`.

`pre_delete`

`django.db.models.signals.pre_delete`

Sent at the beginning of a model's `delete()` method and a queryset's `delete()` method.

Arguments sent with this signal:

sender

The model class.

instance

The actual instance being deleted.

using

The database alias being used.

origin

The origin of the deletion being the instance of a `Model` or `QuerySet` class.

`post_delete`

`django.db.models.signals.post_delete`

Like `pre_delete`, but sent at the end of a model's `delete()` method and a queryset's `delete()` method.

Arguments sent with this signal:

sender

The model class.

instance

The actual instance being deleted.

Note that the object will no longer be in the database, so be very careful what you do with this instance.

using

The database alias being used.

origin

The origin of the deletion being the instance of a `Model` or `QuerySet` class.

`m2m_changed`

`django.db.models.signals.m2m_changed`

Sent when a *ManyToManyField* is changed on a model instance. Strictly speaking, this is not a model signal since it is sent by the *ManyToManyField*, but since it complements the *pre_save/post_save* and *pre_delete/post_delete* when it comes to tracking changes to models, it is included here.

Arguments sent with this signal:

sender

The intermediate model class describing the *ManyToManyField*. This class is automatically created when a many-to-many field is defined; you can access it using the `through` attribute on the many-to-many field.

instance

The instance whose many-to-many relation is updated. This can be an instance of the **sender**, or of the class the *ManyToManyField* is related to.

action

A string indicating the type of update that is done on the relation. This can be one of the following:

"pre_add"

Sent before one or more objects are added to the relation.

"post_add"

Sent after one or more objects are added to the relation.

"pre_remove"

Sent before one or more objects are removed from the relation.

"post_remove"

Sent after one or more objects are removed from the relation.

"pre_clear"

Sent before the relation is cleared.

"post_clear"

Sent after the relation is cleared.

reverse

Indicates which side of the relation is updated (i.e., if it is the forward or reverse relation that is being modified).

model

The class of the objects that are added to, removed from or cleared from the relation.

pk_set

For the *pre_add* and *post_add* actions, this is a set of primary key values that will be, or have been,

added to the relation. This may be a subset of the values submitted to be added, since inserts must filter existing values in order to avoid a database `IntegrityError`.

For the `pre_remove` and `post_remove` actions, this is a set of primary key values that was submitted to be removed from the relation. This is not dependent on whether the values actually will be, or have been, removed. In particular, non-existent values may be submitted, and will appear in `pk_set`, even though they have no effect on the database.

For the `pre_clear` and `post_clear` actions, this is `None`.

using

The database alias being used.

For example, if a `Pizza` can have multiple `Topping` objects, modeled like this:

```
class Topping(models.Model):
    # ...
    pass

class Pizza(models.Model):
    # ...
    toppings = models.ManyToManyField(Topping)
```

If we connected a handler like this:

```
from django.db.models.signals import m2m_changed

def toppings_changed(sender, **kwargs):
    # Do something
    pass

m2m_changed.connect(toppings_changed, sender=Pizza.toppings.through)
```

and then did something like this:

```
>>> p = Pizza.objects.create(...)
>>> t = Topping.objects.create(...)
>>> p.toppings.add(t)
```

the arguments sent to a `m2m_changed` handler (`toppings_changed` in the example above) would be:

Argument	Value
<code>sender</code>	<code>Pizza.toppings.through</code> (the intermediate m2m class)
<code>instance</code>	<code>p</code> (the <code>Pizza</code> instance being modified)
<code>action</code>	"pre_add" (followed by a separate signal with "post_add")
<code>reverse</code>	False (<code>Pizza</code> contains the <i>ManyToManyField</i> , so this call modifies the forward relation)
<code>model</code>	<code>Topping</code> (the class of the objects added to the <code>Pizza</code>)
<code>pk_set</code>	<code>{t.id}</code> (since only <code>Topping t</code> was added to the relation)
<code>using</code>	"default" (since the default router sends writes here)

And if we would then do something like this:

```
>>> t.pizza_set.remove(p)
```

the arguments sent to a *m2m_changed* handler would be:

Argument	Value
<code>sender</code>	<code>Pizza.toppings.through</code> (the intermediate m2m class)
<code>instance</code>	<code>t</code> (the <code>Topping</code> instance being modified)
<code>action</code>	"pre_remove" (followed by a separate signal with "post_remove")
<code>reverse</code>	True (<code>Pizza</code> contains the <i>ManyToManyField</i> , so this call modifies the reverse relation)
<code>model</code>	<code>Pizza</code> (the class of the objects removed from the <code>Topping</code>)
<code>pk_set</code>	<code>{p.id}</code> (since only <code>Pizza p</code> was removed from the relation)
<code>using</code>	"default" (since the default router sends writes here)

class_prepared

`django.db.models.signals.class_prepared`

Sent whenever a model class has been “prepared” –that is, once a model has been defined and registered with Django’s model system. Django uses this signal internally; it’s not generally used in third-party applications.

Since this signal is sent during the app registry population process, and *AppConfig.ready()* runs after the app registry is fully populated, receivers cannot be connected in that method. One possibility is to connect them *AppConfig.__init__()* instead, taking care not to import models or trigger calls to the app registry.

Arguments that are sent with this signal:

sender

The model class which was just prepared.

6.21.2 Management signals

Signals sent by `django-admin`.

`pre_migrate`

`django.db.models.signals.pre_migrate`

Sent by the `migrate` command before it starts to install an application. It's not emitted for applications that lack a `models` module.

Arguments sent with this signal:

sender

An *AppConfig* instance for the application about to be migrated/synced.

app_config

Same as **sender**.

verbosity

Indicates how much information `manage.py` is printing on screen. See the `--verbosity` flag for details.

Functions which listen for `pre_migrate` should adjust what they output to the screen based on the value of this argument.

interactive

If `interactive` is `True`, it's safe to prompt the user to input things on the command line. If `interactive` is `False`, functions which listen for this signal should not try to prompt for anything.

For example, the `django.contrib.auth` app only prompts to create a superuser when `interactive` is `True`.

stdout

A stream-like object where verbose output should be redirected.

using

The alias of database on which a command will operate.

plan

The migration plan that is going to be used for the migration run. While the plan is not public API, this allows for the rare cases when it is necessary to know the plan. A plan is a list of two-tuples with the first item being the instance of a migration class and the second item showing if the migration was rolled back (`True`) or applied (`False`).

apps

An instance of *Apps* containing the state of the project before the migration run. It should be used instead of the global *apps* registry to retrieve the models you want to perform operations on.

`post_migrate`

`django.db.models.signals.post_migrate`

Sent at the end of the `migrate` (even if no migrations are run) and `flush` commands. It's not emitted for applications that lack a `models` module.

Handlers of this signal must not perform database schema alterations as doing so may cause the `flush` command to fail if it runs during the `migrate` command.

Arguments sent with this signal:

sender

An `AppConfig` instance for the application that was just installed.

app_config

Same as `sender`.

verbosity

Indicates how much information `manage.py` is printing on screen. See the `--verbosity` flag for details.

Functions which listen for `post_migrate` should adjust what they output to the screen based on the value of this argument.

interactive

If `interactive` is `True`, it's safe to prompt the user to input things on the command line. If `interactive` is `False`, functions which listen for this signal should not try to prompt for anything.

For example, the `django.contrib.auth` app only prompts to create a superuser when `interactive` is `True`.

stdout

A stream-like object where verbose output should be redirected.

using

The database alias used for synchronization. Defaults to the `default` database.

plan

The migration plan that was used for the migration run. While the plan is not public API, this allows for the rare cases when it is necessary to know the plan. A plan is a list of two-tuples with the first item being the instance of a migration class and the second item showing if the migration was rolled back (`True`) or applied (`False`).

apps

An instance of `Apps` containing the state of the project after the migration run. It should be used instead of the global `apps` registry to retrieve the models you want to perform operations on.

For example, you could register a callback in an `AppConfig` like this:

```
from django.apps import AppConfig
from django.db.models.signals import post_migrate

def my_callback(sender, **kwargs):
    # Your specific logic here
    pass

class MyAppConfig(AppConfig):
    ...

    def ready(self):
        post_migrate.connect(my_callback, sender=self)
```

Note: If you provide an [AppConfig](#) instance as the sender argument, please ensure that the signal is registered in [ready\(\)](#). AppConfigs are recreated for tests that run with a modified set of [INSTALLED_APPS](#) (such as when settings are overridden) and such signals should be connected for each new `AppConfig` instance.

6.21.3 Request/response signals

Signals sent by the core framework when processing a request.

Warning: Signals can make your code harder to maintain. Consider [using a middleware](#) before using request/response signals.

`request_started`

`django.core.signals.request_started`

Sent when Django begins processing an HTTP request.

Arguments sent with this signal:

sender

The handler class –e.g. `django.core.handlers.wsgi.WsgiHandler` –that handled the request.

environ

The `environ` dictionary provided to the request.

`request_finished`

`django.core.signals.request_finished`

Sent when Django finishes delivering an HTTP response to the client.

Arguments sent with this signal:

sender

The handler class, as above.

`got_request_exception`

`django.core.signals.got_request_exception`

This signal is sent whenever Django encounters an exception while processing an incoming HTTP request.

Arguments sent with this signal:

sender

Unused (always `None`).

request

The *HttpRequest* object.

6.21.4 Test signals

Signals only sent when [running tests](#).

`setting_changed`

`django.test.signals.setting_changed`

This signal is sent when the value of a setting is changed through the `django.test.TestCase.settings()` context manager or the `django.test.override_settings()` decorator/context manager.

It's actually sent twice: when the new value is applied (“setup”) and when the original value is restored (“teardown”). Use the `enter` argument to distinguish between the two.

You can also import this signal from `django.core.signals` to avoid importing from `django.test` in non-test situations.

Arguments sent with this signal:

sender

The settings handler.

setting

The name of the setting.

value

The value of the setting after the change. For settings that initially don't exist, in the “teardown” phase, value is `None`.

enter

A boolean; `True` if the setting is applied, `False` if restored.

template_rendered**`django.test.signals.template_rendered`**

Sent when the test system renders a template. This signal is not emitted during normal operation of a Django server –it is only available during testing.

Arguments sent with this signal:

sender

The *Template* object which was rendered.

template

Same as sender

context

The *Context* with which the template was rendered.

6.21.5 Database Wrappers

Signals sent by the database wrapper when a database connection is initiated.

connection_created**`django.db.backends.signals.connection_created`**

Sent when the database wrapper makes the initial connection to the database. This is particularly useful if you'd like to send any post connection commands to the SQL backend.

Arguments sent with this signal:

sender

The database wrapper class –i.e. `django.db.backends.postgresql.DatabaseWrapper` or `django.db.backends.mysql.DatabaseWrapper`, etc.

connection

The database connection that was opened. This can be used in a multiple-database configuration to differentiate connection signals from different databases.

6.22 Templates

Django’s template engine provides a powerful mini-language for defining the user-facing layer of your application, encouraging a clean separation of application and presentation logic. Templates can be maintained by anyone with an understanding of HTML; no knowledge of Python is required. For introductory material, see [Templates](#) topic guide.

6.22.1 The Django template language

This document explains the language syntax of the Django template system. If you’re looking for a more technical perspective on how it works and how to extend it, see [The Django template language: for Python programmers](#).

Django’s template language is designed to strike a balance between power and ease. It’s designed to feel comfortable to those used to working with HTML. If you have any exposure to other text-based template languages, such as [Smarty](#) or [Jinja2](#), you should feel right at home with Django’s templates.

Philosophy

If you have a background in programming, or if you’re used to languages which mix programming code directly into HTML, you’ll want to bear in mind that the Django template system is not simply Python embedded into HTML. This is by design: the template system is meant to express presentation, not program logic.

The Django template system provides tags which function similarly to some programming constructs –an *if* tag for boolean tests, a *for* tag for looping, etc. –but these are not simply executed as the corresponding Python code, and the template system will not execute arbitrary Python expressions. Only the tags, filters and syntax listed below are supported by default (although you can add [your own extensions](#) to the template language as needed).

Templates

A template is a text file. It can generate any text-based format (HTML, XML, CSV, etc.).

A template contains variables, which get replaced with values when the template is evaluated, and tags, which control the logic of the template.

Below is a minimal template that illustrates a few basics. Each element will be explained later in this document.

```
{% extends "base_generic.html" %}
```

(continues on next page)

(continued from previous page)

```
{% block title %}{% section.title %}{% endblock %}

{% block content %}
<h1>{% section.title %}</h1>

{% for story in story_list %}
<h2>
  <a href="{% story.get_absolute_url %}">
    {% story.headline|upper %}
  </a>
</h2>
<p>{% story.tease|truncatewords:"100" %}</p>
{% endfor %}
{% endblock %}
```

Philosophy

Why use a text-based template instead of an XML-based one (like Zope's TAL)? We wanted Django's template language to be usable for more than just XML/HTML templates. You can use the template language for any text-based format such as emails, JavaScript and CSV.

Variables

Variables look like this: `{{ variable }}`. When the template engine encounters a variable, it evaluates that variable and replaces it with the result. Variable names consist of any combination of alphanumeric characters and the underscore ("`_`") but may not start with an underscore, and may not be a number. The dot ("`.`") also appears in variable sections, although that has a special meaning, as indicated below. Importantly, you cannot have spaces or punctuation characters in variable names.

Use a dot (`.`) to access attributes of a variable.

Behind the scenes

Technically, when the template system encounters a dot, it tries the following lookups, in this order:

- Dictionary lookup
- Attribute or method lookup
- Numeric index lookup

If the resulting value is callable, it is called with no arguments. The result of the call becomes the template value.

This lookup order can cause some unexpected behavior with objects that override dictionary lookup. For example, consider the following code snippet that attempts to loop over a `collections.defaultdict`:

```
{% for k, v in defaultdict.items %}
    Do something with k and v here...
{% endfor %}
```

Because dictionary lookup happens first, that behavior kicks in and provides a default value instead of using the intended `.items()` method. In this case, consider converting to a dictionary first.

In the above example, `{{ section.title }}` will be replaced with the `title` attribute of the `section` object.

If you use a variable that doesn't exist, the template system will insert the value of the `string_if_invalid` option, which is set to `' '` (the empty string) by default.

Note that `"bar"` in a template expression like `{{ foo.bar }}` will be interpreted as a literal string and not using the value of the variable `"bar"`, if one exists in the template context.

Variable attributes that begin with an underscore may not be accessed as they're generally considered private.

Filters

You can modify variables for display by using filters.

Filters look like this: `{{ name|lower }}`. This displays the value of the `{{ name }}` variable after being filtered through the `lower` filter, which converts text to lowercase. Use a pipe (`|`) to apply a filter.

Filters can be “chained.” The output of one filter is applied to the next. `{{ text|escape|linebreaks }}` is a common idiom for escaping text contents, then converting line breaks to `<p>` tags.

Some filters take arguments. A filter argument looks like this: `{{ bio|truncatewords:30 }}`. This will display the first 30 words of the `bio` variable.

Filter arguments that contain spaces must be quoted; for example, to join a list with commas and spaces you'd use `{{ list|join:", " }}`.

Django provides about sixty built-in template filters. You can read all about them in the [built-in filter reference](#). To give you a taste of what's available, here are some of the more commonly used template filters:

`default`

If a variable is false or empty, use given default. Otherwise, use the value of the variable. For example:

```
{{ value|default:"nothing" }}
```

If `value` isn't provided or is empty, the above will display `"nothing"`.

length

Returns the length of the value. This works for both strings and lists. For example:

```
{{ value|length }}
```

If value is ['a', 'b', 'c', 'd'], the output will be 4.

filesizeformat

Formats the value like a “human-readable” file size (i.e. '13 KB', '4.1 MB', '102 bytes', etc.). For example:

```
{{ value|filesizeformat }}
```

If value is 123456789, the output would be 117.7 MB.

Again, these are just a few examples; see the [built-in filter reference](#) for the complete list.

You can also create your own custom template filters; see [How to create custom template tags and filters](#).

See also:

Django’s admin interface can include a complete reference of all template tags and filters available for a given site. See [The Django admin documentation generator](#).

Tags

Tags look like this: {% tag %}. Tags are more complex than variables: Some create text in the output, some control flow by performing loops or logic, and some load external information into the template to be used by later variables.

Some tags require beginning and ending tags (i.e. {% tag %} ... tag contents ... {% endtag %}).

Django ships with about two dozen built-in template tags. You can read all about them in the [built-in tag reference](#). To give you a taste of what’s available, here are some of the more commonly used tags:

for

Loop over each item in an array. For example, to display a list of athletes provided in `athlete_list`:

```
<ul>
{% for athlete in athlete_list %}
    <li>{{ athlete.name }}</li>
{% endfor %}
</ul>
```

if, elif, and else

Evaluates a variable, and if that variable is “true” the contents of the block are displayed:

```
{% if athlete_list %}
    Number of athletes: {{ athlete_list|length }}
{% elif athlete_in_locker_room_list %}
    Athletes should be out of the locker room soon!
{% else %}
    No athletes.
{% endif %}
```

In the above, if `athlete_list` is not empty, the number of athletes will be displayed by the `{{ athlete_list|length }}` variable. Otherwise, if `athlete_in_locker_room_list` is not empty, the message “Athletes should be out...” will be displayed. If both lists are empty, “No athletes.” will be displayed.

You can also use filters and various operators in the `if` tag:

```
{% if athlete_list|length > 1 %}
    Team: {% for athlete in athlete_list %} ... {% endfor %}
{% else %}
    Athlete: {{ athlete_list.0.name }}
{% endif %}
```

While the above example works, be aware that most template filters return strings, so mathematical comparisons using filters will generally not work as you expect. `length` is an exception.

`block` and `extends`

Set up [template inheritance](#) (see below), a powerful way of cutting down on “boilerplate” in templates.

Again, the above is only a selection of the whole list; see the [built-in tag reference](#) for the complete list.

You can also create your own custom template tags; see [How to create custom template tags and filters](#).

See also:

Django’s admin interface can include a complete reference of all template tags and filters available for a given site. See [The Django admin documentation generator](#).

Comments

To comment-out part of a line in a template, use the comment syntax: `{# #}`.

For example, this template would render as ‘hello’:

```
{# greeting #}hello
```

A comment can contain any template code, invalid or not. For example:

```
{# {% if foo %}bar{% else %} #}
```

This syntax can only be used for single-line comments (no newlines are permitted between the `{#` and `#}` delimiters). If you need to comment out a multiline portion of the template, see the [comment](#) tag.

Template inheritance

The most powerful –and thus the most complex –part of Django’s template engine is template inheritance. Template inheritance allows you to build a base “skeleton” template that contains all the common elements of your site and defines blocks that child templates can override.

Let’s look at template inheritance by starting with an example:

```
<!DOCTYPE html>
<html lang="en">
<head>
    <link rel="stylesheet" href="style.css">
    <title>{% block title %}My amazing site{% endblock %}</title>
</head>

<body>
    <div id="sidebar">
        {% block sidebar %}
        <ul>
            <li><a href="/">Home</a></li>
            <li><a href="/blog/">Blog</a></li>
        </ul>
        {% endblock %}
    </div>

    <div id="content">
        {% block content %}{% endblock %}
    </div>
</body>
</html>
```

This template, which we’ll call `base.html`, defines an HTML skeleton document that you might use for a two-column page. It’s the job of “child” templates to fill the empty blocks with content.

In this example, the `block` tag defines three blocks that child templates can fill in. All the `block` tag does is to tell the template engine that a child template may override those portions of the template.

A child template might look like this:

```
{% extends "base.html" %}

{% block title %}My amazing blog{% endblock %}

{% block content %}
{% for entry in blog_entries %}
    <h2>{{ entry.title }}</h2>
    <p>{{ entry.body }}</p>
{% endfor %}
{% endblock %}
```

The `extends` tag is the key here. It tells the template engine that this template “extends” another template. When the template system evaluates this template, first it locates the parent—in this case, “base.html”.

At that point, the template engine will notice the three `block` tags in `base.html` and replace those blocks with the contents of the child template. Depending on the value of `blog_entries`, the output might look like:

```
<!DOCTYPE html>
<html lang="en">
<head>
    <link rel="stylesheet" href="style.css">
    <title>My amazing blog</title>
</head>

<body>
    <div id="sidebar">
        <ul>
            <li><a href="/">Home</a></li>
            <li><a href="/blog/">Blog</a></li>
        </ul>
    </div>

    <div id="content">
        <h2>Entry one</h2>
        <p>This is my first entry.</p>

        <h2>Entry two</h2>
        <p>This is my second entry.</p>
    </div>
</body>
</html>
```

Note that since the child template didn’t define the `sidebar` block, the value from the parent template is used instead. Content within a `{% block %}` tag in a parent template is always used as a fallback.

You can use as many levels of inheritance as needed. One common way of using inheritance is the following three-level approach:

- Create a `base.html` template that holds the main look-and-feel of your site.
- Create a `base_SECTIONNAME.html` template for each “section” of your site. For example, `base_news.html`, `base_sports.html`. These templates all extend `base.html` and include section-specific styles/design.
- Create individual templates for each type of page, such as a news article or blog entry. These templates extend the appropriate section template.

This approach maximizes code reuse and helps to add items to shared content areas, such as section-wide navigation.

Here are some tips for working with inheritance:

- If you use `{% extends %}` in a template, it must be the first template tag in that template. Template inheritance won’t work, otherwise.
- More `{% block %}` tags in your base templates are better. Remember, child templates don’t have to define all parent blocks, so you can fill in reasonable defaults in a number of blocks, then only define the ones you need later. It’s better to have more hooks than fewer hooks.
- If you find yourself duplicating content in a number of templates, it probably means you should move that content to a `{% block %}` in a parent template.
- If you need to get the content of the block from the parent template, the `{{ block.super }}` variable will do the trick. This is useful if you want to add to the contents of a parent block instead of completely overriding it. Data inserted using `{{ block.super }}` will not be automatically escaped (see the [next section](#)), since it was already escaped, if necessary, in the parent template.
- By using the same template name as you are inheriting from, `{% extends %}` can be used to inherit a template at the same time as overriding it. Combined with `{{ block.super }}`, this can be a powerful way to make small customizations. See [Extending an overridden template](#) in the [Overriding templates](#) How-to for a full example.
- Variables created outside of a `{% block %}` using the template tag as syntax can’t be used inside the block. For example, this template doesn’t render anything:

```
{% translate "Title" as title %}
{% block content %}{{ title }}{% endblock %}
```

- For extra readability, you can optionally give a name to your `{% endblock %}` tag. For example:

```
{% block content %}
...
{% endblock content %}
```

In larger templates, this technique helps you see which `{% block %}` tags are being closed.

- `{% block %}` tags are evaluated first. That’s why the content of a block is always overridden, regardless of the truthiness of surrounding tags. For example, this template will always override the content of the `title` block:

```
{% if change_title %}
    {% block title %}Hello!{% endblock title %}
{% endif %}
```

Finally, note that you can’t define multiple `block` tags with the same name in the same template. This limitation exists because a block tag works in “both” directions. That is, a block tag doesn’t just provide a hole to fill—it also defines the content that fills the hole in the parent. If there were two similarly-named `block` tags in a template, that template’s parent wouldn’t know which one of the blocks’ content to use.

Automatic HTML escaping

When generating HTML from templates, there’s always a risk that a variable will include characters that affect the resulting HTML. For example, consider this template fragment:

```
Hello, {{ name }}
```

At first, this seems like a harmless way to display a user’s name, but consider what would happen if the user entered their name as this:

```
<script>alert('hello')</script>
```

With this name value, the template would be rendered as:

```
Hello, <script>alert('hello')</script>
```

...which means the browser would pop-up a JavaScript alert box!

Similarly, what if the name contained a `'<'` symbol, like this?

```
<b>username
```

That would result in a rendered template like this:

```
Hello, <b>username
```

...which, in turn, would result in the remainder of the web page being in bold!

Clearly, user-submitted data shouldn’t be trusted blindly and inserted directly into your web pages, because a malicious user could use this kind of hole to do potentially bad things. This type of security exploit is called a [Cross Site Scripting \(XSS\) attack](#).

To avoid this problem, you have two options:

- One, you can make sure to run each untrusted variable through the *escape* filter (documented below), which converts potentially harmful HTML characters to unarmful ones. This was the default solution in Django for its first few years, but the problem is that it puts the onus on you, the developer / template author, to ensure you're escaping everything. It's easy to forget to escape data.
- Two, you can take advantage of Django's automatic HTML escaping. The remainder of this section describes how auto-escaping works.

By default in Django, every template automatically escapes the output of every variable tag. Specifically, these five characters are escaped:

- `<` is converted to `<`;
- `>` is converted to `>`;
- `'` (single quote) is converted to `'`;
- `"` (double quote) is converted to `"`;
- `&` is converted to `&`;

Again, we stress that this behavior is on by default. If you're using Django's template system, you're protected.

How to turn it off

If you don't want data to be auto-escaped, on a per-site, per-template level or per-variable level, you can turn it off in several ways.

Why would you want to turn it off? Because sometimes, template variables contain data that you intend to be rendered as raw HTML, in which case you don't want their contents to be escaped. For example, you might store a blob of HTML in your database and want to embed that directly into your template. Or, you might be using Django's template system to produce text that is not HTML –like an email message, for instance.

For individual variables

To disable auto-escaping for an individual variable, use the *safe* filter:

```
This will be escaped: {{ data }}
This will not be escaped: {{ data|safe }}
```

Think of *safe* as shorthand for safe from further escaping or can be safely interpreted as HTML. In this example, if *data* contains `'<b>'`, the output will be:

```
This will be escaped: &lt;b&gt;
This will not be escaped: <b>
```

For template blocks

To control auto-escaping for a template, wrap the template (or a particular section of the template) in the *autoescape* tag, like so:

```
{% autoescape off %}
    Hello {{ name }}
{% endautoescape %}
```

The *autoescape* tag takes either *on* or *off* as its argument. At times, you might want to force auto-escaping when it would otherwise be disabled. Here is an example template:

```
Auto-escaping is on by default. Hello {{ name }}

{% autoescape off %}
    This will not be auto-escaped: {{ data }}.

    Nor this: {{ other_data }}
{% autoescape on %}
    Auto-escaping applies again: {{ name }}
{% endautoescape %}
{% endautoescape %}
```

The auto-escaping tag passes its effect onto templates that extend the current one as well as templates included via the *include* tag, just like all block tags. For example:

Listing 14: base.html

```
{% autoescape off %}
<h1>{% block title %}{% endblock %}</h1>
{% block content %}
{% endblock %}
{% endautoescape %}
```

Listing 15: child.html

```
{% extends "base.html" %}
{% block title %}This & that{% endblock %}
{% block content %}{{ greeting }}{% endblock %}
```

Because auto-escaping is turned off in the base template, it will also be turned off in the child template, resulting in the following rendered HTML when the *greeting* variable contains the string `<b>Hello!</b>`:

```
<h1>This & that</h1>
<b>Hello!</b>
```

Notes

Generally, template authors don't need to worry about auto-escaping very much. Developers on the Python side (people writing views and custom filters) need to think about the cases in which data shouldn't be escaped, and mark data appropriately, so things Just Work in the template.

If you're creating a template that might be used in situations where you're not sure whether auto-escaping is enabled, then add an `escape` filter to any variable that needs escaping. When auto-escaping is on, there's no danger of the `escape` filter double-escaping data –the `escape` filter does not affect auto-escaped variables.

String literals and automatic escaping

As we mentioned earlier, filter arguments can be strings:

```
{{ data|default:"This is a string literal." }}
```

All string literals are inserted without any automatic escaping into the template –they act as if they were all passed through the `safe` filter. The reasoning behind this is that the template author is in control of what goes into the string literal, so they can make sure the text is correctly escaped when the template is written.

This means you would write :

```
{{ data|default:"3 &lt; 2" }}
```

...rather than:

```
{{ data|default:"3 < 2" }} {# Bad! Don't do this. #}
```

This doesn't affect what happens to data coming from the variable itself. The variable's contents are still automatically escaped, if necessary, because they're beyond the control of the template author.

Accessing method calls

Most method calls attached to objects are also available from within templates. This means that templates have access to much more than just class attributes (like field names) and variables passed in from views. For example, the Django ORM provides the `“entry_set”` syntax for finding a collection of objects related on a foreign key. Therefore, given a model called `“comment”` with a foreign key relationship to a model called `“task”` you can loop through all comments attached to a given task like this:

```
{% for comment in task.comment_set.all %}
    {{ comment }}
{% endfor %}
```

Similarly, `QuerySets` provide a `count()` method to count the number of objects they contain. Therefore, you can obtain a count of all comments related to the current task with:

```
{{ task.comment_set.all.count }}
```

You can also access methods you’ve explicitly defined on your own models:

Listing 16: `models.py`

```
class Task(models.Model):
    def foo(self):
        return "bar"
```

Listing 17: `template.html`

```
{{ task.foo }}
```

Because Django intentionally limits the amount of logic processing available in the template language, it is not possible to pass arguments to method calls accessed from within templates. Data should be calculated in views, then passed to templates for display.

Custom tag and filter libraries

Certain applications provide custom tag and filter libraries. To access them in a template, ensure the application is in *INSTALLED_APPS* (we’d add `'django.contrib.humanize'` for this example), and then use the *load* tag in a template:

```
{% load humanize %}

{{ 45000|intcomma }}
```

In the above, the *load* tag loads the *humanize* tag library, which then makes the *intcomma* filter available for use. If you’ve enabled *django.contrib.admindocs*, you can consult the documentation area in your admin to find the list of custom libraries in your installation.

The *load* tag can take multiple library names, separated by spaces. Example:

```
{% load humanize i18n %}
```

See [How to create custom template tags and filters](#) for information on writing your own custom template libraries.

Custom libraries and template inheritance

When you load a custom tag or filter library, the tags/filters are only made available to the current template –not any parent or child templates along the template-inheritance path.

For example, if a template `foo.html` has `{% load humanize %}`, a child template (e.g., one that has `{% extends "foo.html" %}`) will not have access to the `humanize` template tags and filters. The child template is responsible for its own `{% load humanize %}`.

This is a feature for the sake of maintainability and sanity.

See also:

[The Templates Reference](#)

Covers built-in tags, built-in filters, using an alternative template language, and more.

6.22.2 Built-in template tags and filters

This document describes Django’s built-in template tags and filters. It is recommended that you use the [automatic documentation](#), if available, as this will also include documentation for any custom tags or filters installed.

Built-in tag reference

`autoescape`

Controls the current auto-escaping behavior. This tag takes either `on` or `off` as an argument and that determines whether auto-escaping is in effect inside the block. The block is closed with an `endautoescape` ending tag.

Sample usage:

```
{% autoescape on %}
    {{ body }}
{% endautoescape %}
```

When auto-escaping is in effect, all content derived from variables has HTML escaping applied before placing the result into the output (but after any filters are applied). This is equivalent to manually applying the `escape` filter to each variable.

The only exceptions are variables already marked as “safe” from escaping. Variables could be marked as “safe” by the code which populated the variable, by applying the `safe` or `escape` filters, or because it’s the result of a previous filter that marked the string as “safe”.

Within the scope of disabled auto-escaping, chaining filters, including `escape`, may cause unexpected (but documented) results such as the following:

```
{% autoescape off %}
    {{ my_list|join:", "|escape }}
{% endautoescape %}
```

The above code will output the joined elements of `my_list` unescaped. This is because the filter chaining sequence executes first `join` on `my_list` (without applying escaping to each item since `autoescape` is off), marking the result as safe. Subsequently, this safe result will be fed to `escape` filter, which does not apply a second round of escaping.

block

Defines a block that can be overridden by child templates. See [Template inheritance](#) for more information.

comment

Ignores everything between `{% comment %}` and `{% endcomment %}`. An optional note may be inserted in the first tag. For example, this is useful when commenting out code for documenting why the code was disabled.

Sample usage:

```
<p>Rendered text with {{ pub_date|date:"c" }}</p>
{% comment "Optional note" %}
    <p>Commented out text with {{ create_date|date:"c" }}</p>
{% endcomment %}
```

`comment` tags cannot be nested.

csrf_token

This tag is used for CSRF protection, as described in the documentation for [Cross Site Request Forgeries](#).

cycle

Produces one of its arguments each time this tag is encountered. The first argument is produced on the first encounter, the second argument on the second encounter, and so forth. Once all arguments are exhausted, the tag cycles to the first argument and produces it again.

This tag is particularly useful in a loop:

```
{% for o in some_list %}
    <tr class="{% cycle 'row1' 'row2' %}">
        ...
```

(continues on next page)

(continued from previous page)

```

    </tr>
{% endfor %}

```

The first iteration produces HTML that refers to class `row1`, the second to `row2`, the third to `row1` again, and so on for each iteration of the loop.

You can use variables, too. For example, if you have two template variables, `rowvalue1` and `rowvalue2`, you can alternate between their values like this:

```

{% for o in some_list %}
    <tr class="{% cycle rowvalue1 rowvalue2 %}">
        ...
    </tr>
{% endfor %}

```

Variables included in the cycle will be escaped. You can disable auto-escaping with:

```

{% for o in some_list %}
    <tr class="{% autoescape off %}{% cycle rowvalue1 rowvalue2 %}{% endautoescape %}">
        ...
    </tr>
{% endfor %}

```

You can mix variables and strings:

```

{% for o in some_list %}
    <tr class="{% cycle 'row1' rowvalue2 'row3' %}">
        ...
    </tr>
{% endfor %}

```

In some cases you might want to refer to the current value of a cycle without advancing to the next value. To do this, give the `{% cycle %}` tag a name, using “as”, like this:

```

{% cycle 'row1' 'row2' as rowcolors %}

```

From then on, you can insert the current value of the cycle wherever you’d like in your template by referencing the cycle name as a context variable. If you want to move the cycle to the next value independently of the original cycle tag, you can use another cycle tag and specify the name of the variable. So, the following template:

```

<tr>
    <td class="{% cycle 'row1' 'row2' as rowcolors %}">...</td>
    <td class="{ rowcolors }">...</td>

```

(continues on next page)

(continued from previous page)

```

</tr>
<tr>
    <td class="{% cycle rowcolors %}">...</td>
    <td class="{ rowcolors }">...</td>
</tr>

```

would output:

```

<tr>
    <td class="row1">...</td>
    <td class="row1">...</td>
</tr>
<tr>
    <td class="row2">...</td>
    <td class="row2">...</td>
</tr>

```

You can use any number of values in a `cycle` tag, separated by spaces. Values enclosed in single quotes (`'`) or double quotes (`"`) are treated as string literals, while values without quotes are treated as template variables.

By default, when you use the `as` keyword with the `cycle` tag, the usage of `{% cycle %}` that initiates the cycle will itself produce the first value in the cycle. This could be a problem if you want to use the value in a nested loop or an included template. If you only want to declare the cycle but not produce the first value, you can add a `silent` keyword as the last keyword in the tag. For example:

```

{% for obj in some_list %}
    {% cycle 'row1' 'row2' as rowcolors silent %}
    <tr class="{ rowcolors }">{% include "subtemplate.html" %}</tr>
{% endfor %}

```

This will output a list of `<tr>` elements with `class` alternating between `row1` and `row2`. The subtemplate will have access to `rowcolors` in its context and the value will match the class of the `<tr>` that encloses it. If the `silent` keyword were to be omitted, `row1` and `row2` would be emitted as normal text, outside the `<tr>` element.

When the `silent` keyword is used on a cycle definition, the silence automatically applies to all subsequent uses of that specific cycle tag. The following template would output nothing, even though the second call to `{% cycle %}` doesn't specify `silent`:

```

{% cycle 'row1' 'row2' as rowcolors silent %}
{% cycle rowcolors %}

```

You can use the `resetcycle` tag to make a `{% cycle %}` tag restart from its first value when it's next encountered.

debug

Outputs a whole load of debugging information, including the current context and imported modules. `{% debug %}` outputs nothing when the `DEBUG` setting is `False`.

In older versions, debugging information was displayed when the `DEBUG` setting was `False`.

extends

Signals that this template extends a parent template.

This tag can be used in two ways:

- `{% extends "base.html" %}` (with quotes) uses the literal value `"base.html"` as the name of the parent template to extend.
- `{% extends variable %}` uses the value of `variable`. If the variable evaluates to a string, Django will use that string as the name of the parent template. If the variable evaluates to a `Template` object, Django will use that object as the parent template.

See [Template inheritance](#) for more information.

Normally the template name is relative to the template loader's root directory. A string argument may also be a relative path starting with `./` or `../`. For example, assume the following directory structure:

```
dir1/
  template.html
  base2.html
  my/
    base3.html
base1.html
```

In `template.html`, the following paths would be valid:

```
{% extends "./base2.html" %}
{% extends "../base1.html" %}
{% extends "./my/base3.html" %}
```

filter

Filters the contents of the block through one or more filters. Multiple filters can be specified with pipes and filters can have arguments, just as in variable syntax.

Note that the block includes all the text between the `filter` and `endfilter` tags.

Sample usage:

```
{% filter force_escape|lower %}
```

This text will be HTML-escaped, and will appear in all lowercase.

```
{% endfilter %}
```

Note: The `escape` and `safe` filters are not acceptable arguments. Instead, use the `autoescape` tag to manage autoescaping for blocks of template code.

firstof

Outputs the first argument variable that is not “false” (i.e. exists, is not empty, is not a false boolean value, and is not a zero numeric value). Outputs nothing if all the passed variables are “false” .

Sample usage:

```
{% firstof var1 var2 var3 %}
```

This is equivalent to:

```
{% if var1 %}
    {{ var1 }}
{% elif var2 %}
    {{ var2 }}
{% elif var3 %}
    {{ var3 }}
{% endif %}
```

You can also use a literal string as a fallback value in case all passed variables are False:

```
{% firstof var1 var2 var3 "fallback value" %}
```

This tag auto-escapes variable values. You can disable auto-escaping with:

```
{% autoescape off %}
    {% firstof var1 var2 var3 "<strong>fallback value</strong>" %}
{% endautoescape %}
```

Or if only some variables should be escaped, you can use:

```
{% firstof var1 var2|safe var3 "<strong>fallback value</strong>"|safe %}
```

You can use the syntax `{% firstof var1 var2 var3 as value %}` to store the output inside a variable.

for

Loops over each item in an array, making the item available in a context variable. For example, to display a list of athletes provided in `athlete_list`:

```
<ul>
{% for athlete in athlete_list %}
    <li>{{ athlete.name }}</li>
{% endfor %}
</ul>
```

You can loop over a list in reverse by using `{% for obj in list reversed %}`.

If you need to loop over a list of lists, you can unpack the values in each sublist into individual variables. For example, if your context contains a list of (x,y) coordinates called `points`, you could use the following to output the list of points:

```
{% for x, y in points %}
    There is a point at {{ x }}, {{ y }}
{% endfor %}
```

This can also be useful if you need to access the items in a dictionary. For example, if your context contained a dictionary `data`, the following would display the keys and values of the dictionary:

```
{% for key, value in data.items %}
    {{ key }}: {{ value }}
{% endfor %}
```

Keep in mind that for the dot operator, dictionary key lookup takes precedence over method lookup. Therefore if the `data` dictionary contains a key named `'items'`, `data.items` will return `data['items']` instead of `data.items()`. Avoid adding keys that are named like dictionary methods if you want to use those methods in a template (`items`, `values`, `keys`, etc.). Read more about the lookup order of the dot operator in the [documentation of template variables](#).

The for loop sets a number of variables available within the loop:

Variable	Description
<code>forloop.counter</code>	The current iteration of the loop (1-indexed)
<code>forloop.counter0</code>	The current iteration of the loop (0-indexed)
<code>forloop.revcounter</code>	The number of iterations from the end of the loop (1-indexed)
<code>forloop.revcounter0</code>	The number of iterations from the end of the loop (0-indexed)
<code>forloop.first</code>	True if this is the first time through the loop
<code>forloop.last</code>	True if this is the last time through the loop
<code>forloop.parentloop</code>	For nested loops, this is the loop surrounding the current one

for ... empty

The `for` tag can take an optional `{% empty %}` clause whose text is displayed if the given array is empty or could not be found:

```
<ul>
{% for athlete in athlete_list %}
    <li>{{ athlete.name }}</li>
{% empty %}
    <li>Sorry, no athletes in this list.</li>
{% endfor %}
</ul>
```

The above is equivalent to –but shorter, cleaner, and possibly faster than –the following:

```
<ul>
    {% if athlete_list %}
        {% for athlete in athlete_list %}
            <li>{{ athlete.name }}</li>
        {% endfor %}
    {% else %}
        <li>Sorry, no athletes in this list.</li>
    {% endif %}
</ul>
```

if

The `{% if %}` tag evaluates a variable, and if that variable is “true” (i.e. exists, is not empty, and is not a false boolean value) the contents of the block are output:

```
{% if athlete_list %}
    Number of athletes: {{ athlete_list|length }}
{% elif athlete_in_locker_room_list %}
    Athletes should be out of the locker room soon!
{% else %}
    No athletes.
{% endif %}
```

In the above, if `athlete_list` is not empty, the number of athletes will be displayed by the `{{ athlete_list|length }}` variable.

As you can see, the `if` tag may take one or several `{% elif %}` clauses, as well as an `{% else %}` clause that will be displayed if all previous conditions fail. These clauses are optional.

Boolean operators

`if` tags may use `and`, `or` or `not` to test a number of variables or to negate a given variable:

```
{% if athlete_list and coach_list %}
    Both athletes and coaches are available.
{% endif %}

{% if not athlete_list %}
    There are no athletes.
{% endif %}

{% if athlete_list or coach_list %}
    There are some athletes or some coaches.
{% endif %}

{% if not athlete_list or coach_list %}
    There are no athletes or there are some coaches.
{% endif %}

{% if athlete_list and not coach_list %}
    There are some athletes and absolutely no coaches.
{% endif %}
```

Use of both `and` and `or` clauses within the same tag is allowed, with `and` having higher precedence than `or` e.g.:

```
{% if athlete_list and coach_list or cheerleader_list %}
```

will be interpreted like:

```
if (athlete_list and coach_list) or cheerleader_list
```

Use of actual parentheses in the `if` tag is invalid syntax. If you need them to indicate precedence, you should use nested `if` tags.

`if` tags may also use the operators `==`, `!=`, `<`, `>`, `<=`, `>=`, `in`, `not in`, `is`, and `is not` which work as follows:

== operator

Equality. Example:

```
{% if somevar == "x" %}  
    This appears if variable somevar equals the string "x"  
{% endif %}
```

!= operator

Inequality. Example:

```
{% if somevar != "x" %}  
    This appears if variable somevar does not equal the string "x",  
    or if somevar is not found in the context  
{% endif %}
```

< operator

Less than. Example:

```
{% if somevar < 100 %}  
    This appears if variable somevar is less than 100.  
{% endif %}
```

> operator

Greater than. Example:

```
{% if somevar > 0 %}  
    This appears if variable somevar is greater than 0.  
{% endif %}
```

<= operator

Less than or equal to. Example:

```
{% if somevar <= 100 %}  
    This appears if variable somevar is less than 100 or equal to 100.  
{% endif %}
```

>= operator

Greater than or equal to. Example:

```
{% if somevar >= 1 %}
    This appears if variable somevar is greater than 1 or equal to 1.
{% endif %}
```

in operator

Contained within. This operator is supported by many Python containers to test whether the given value is in the container. The following are some examples of how `x in y` will be interpreted:

```
{% if "bc" in "abcdef" %}
    This appears since "bc" is a substring of "abcdef"
{% endif %}

{% if "hello" in greetings %}
    If greetings is a list or set, one element of which is the string
    "hello", this will appear.
{% endif %}

{% if user in users %}
    If users is a QuerySet, this will appear if user is an
    instance that belongs to the QuerySet.
{% endif %}
```

not in operator

Not contained within. This is the negation of the `in` operator.

is operator

Object identity. Tests if two values are the same object. Example:

```
{% if somevar is True %}
    This appears if and only if somevar is True.
{% endif %}

{% if somevar is None %}
    This appears if somevar is None, or if somevar is not found in the context.
{% endif %}
```

is not operator

Negated object identity. Tests if two values are not the same object. This is the negation of the `is` operator. Example:

```
{% if somevar is not True %}
    This appears if somevar is not True, or if somevar is not found in the
    context.
{% endif %}

{% if somevar is not None %}
    This appears if and only if somevar is not None.
{% endif %}
```

Filters

You can also use filters in the `if` expression. For example:

```
{% if messages|length >= 100 %}
    You have lots of messages today!
{% endif %}
```

Complex expressions

All of the above can be combined to form complex expressions. For such expressions, it can be important to know how the operators are grouped when the expression is evaluated - that is, the precedence rules. The precedence of the operators, from lowest to highest, is as follows:

- or
- and
- not
- in
- ==, !=, <, >, <=, >=

(This follows Python exactly). So, for example, the following complex `if` tag:

```
{% if a == b or c == d and e %}
```

...will be interpreted as:

```
(a == b) or ((c == d) and e)
```

If you need different precedence, you will need to use nested `if` tags. Sometimes that is better for clarity anyway, for the sake of those who do not know the precedence rules.

The comparison operators cannot be ‘chained’ like in Python or in mathematical notation. For example, instead of using:

```
{% if a > b > c %} (WRONG)
```

you should use:

```
{% if a > b and b > c %}
```

`ifchanged`

Check if a value has changed from the last iteration of a loop.

The `{% ifchanged %}` block tag is used within a loop. It has two possible uses.

1. Checks its own rendered contents against its previous state and only displays the content if it has changed. For example, this displays a list of days, only displaying the month if it changes:

```
<h1>Archive for {{ year }}</h1>

{% for date in days %}
    {% ifchanged %}<h3>{{ date|date:"F" }}</h3>{% endifchanged %}
    <a href="{{ date|date:"M/d"|lower }}" />{{ date|date:"j" }}</a>
{% endfor %}
```

2. If given one or more variables, check whether any variable has changed. For example, the following shows the date every time it changes, while showing the hour if either the hour or the date has changed:

```
{% for date in days %}
    {% ifchanged date.date %} {{ date.date }} {% endifchanged %}
    {% ifchanged date.hour date.date %}
        {{ date.hour }}
    {% endifchanged %}
{% endfor %}
```

The `ifchanged` tag can also take an optional `{% else %}` clause that will be displayed if the value has not changed:

```
{% for match in matches %}
    <div style="background-color:
        {% ifchanged match.ballot_id %}
            {% cycle "red" "blue" %}
```

(continues on next page)

(continued from previous page)

```

    {% else %}
        gray
    {% endifchanged %}
">{{ match }}</div>
{% endfor %}

```

include

Loads a template and renders it with the current context. This is a way of “including” other templates within a template.

The template name can either be a variable or a hard-coded (quoted) string, in either single or double quotes.

This example includes the contents of the template “foo/bar.html”:

```
{% include "foo/bar.html" %}
```

Normally the template name is relative to the template loader’s root directory. A string argument may also be a relative path starting with ./ or ../ as described in the *extends* tag.

This example includes the contents of the template whose name is contained in the variable `template_name`:

```
{% include template_name %}
```

The variable may also be any object with a `render()` method that accepts a context. This allows you to reference a compiled `Template` in your context.

Additionally, the variable may be an iterable of template names, in which case the first that can be loaded will be used, as per *select_template()*.

An included template is rendered within the context of the template that includes it. This example produces the output “Hello, John!”:

- Context: variable `person` is set to “John” and variable `greeting` is set to “Hello”.
- Template:

```
{% include "name_snippet.html" %}
```

- The `name_snippet.html` template:

```
{{ greeting }}, {{ person|default:"friend" }}!
```

You can pass additional context to the template using keyword arguments:

```
{% include "name_snippet.html" with person="Jane" greeting="Hello" %}
```

If you want to render the context only with the variables provided (or even no variables at all), use the `only` option. No other variables are available to the included template:

```
{% include "name_snippet.html" with greeting="Hi" only %}
```

Note: The `include` tag should be considered as an implementation of “render this subtemplate and include the HTML”, not as “parse this subtemplate and include its contents as if it were part of the parent”. This means that there is no shared state between included templates –each include is a completely independent rendering process.

Blocks are evaluated before they are included. This means that a template that includes blocks from another will contain blocks that have already been evaluated and rendered - not blocks that can be overridden by, for example, an extending template.

load

Loads a custom template tag set.

For example, the following template would load all the tags and filters registered in `somelibrary` and `otherlibrary` located in package `package`:

```
{% load somelibrary package.otherlibrary %}
```

You can also selectively load individual filters or tags from a library, using the `from` argument. In this example, the template tags/filters named `foo` and `bar` will be loaded from `somelibrary`:

```
{% load foo bar from somelibrary %}
```

See [Custom tag and filter libraries](#) for more information.

lorem

Displays random “lorem ipsum” Latin text. This is useful for providing sample data in templates.

Usage:

```
{% lorem [count] [method] [random] %}
```

The `{% lorem %}` tag can be used with zero, one, two or three arguments. The arguments are:

Argument	Description
<code>count</code>	A number (or variable) containing the number of paragraphs or words to generate (default is 1).
<code>method</code>	Either <code>w</code> for words, <code>p</code> for HTML paragraphs or <code>b</code> for plain-text paragraph blocks (default is <code>b</code>).
<code>random</code>	The word <code>random</code> , which if given, does not use the common paragraph (“Lorem ipsum dolor sit amet...”) when generating text.

Examples:

- `{% lorem %}` will output the common “lorem ipsum” paragraph.
- `{% lorem 3 p %}` will output the common “lorem ipsum” paragraph and two random paragraphs each wrapped in HTML `<p>` tags.
- `{% lorem 2 w random %}` will output two random Latin words.

`now`

Displays the current date and/or time, using a format according to the given string. Such string can contain format specifiers characters as described in the [date](#) filter section.

Example:

```
It is {% now "jS F Y H:i" %}
```

Note that you can backslash-escape a format string if you want to use the “raw” value. In this example, both “o” and “f” are backslash-escaped, because otherwise each is a format string that displays the year and the time, respectively:

```
It is the {% now "jS \o\f F" %}
```

This would display as “It is the 4th of September” .

Note: The format passed can also be one of the predefined ones [DATE_FORMAT](#), [DATETIME_FORMAT](#), [SHORT_DATE_FORMAT](#) or [SHORT_DATETIME_FORMAT](#). The predefined formats may vary depending on the current locale and if [Format localization](#) is enabled, e.g.:

```
It is {% now "SHORT_DATETIME_FORMAT" %}
```

You can also use the syntax `{% now "Y" as current_year %}` to store the output (as a string) inside a variable. This is useful if you want to use `{% now %}` inside a template tag like [blocktranslate](#) for example:

```
{% now "Y" as current_year %}
{% blocktranslate %}Copyright {{ current_year }}{% endblocktranslate %}
```

regroup

Regroups a list of alike objects by a common attribute.

This complex tag is best illustrated by way of an example: say that `cities` is a list of cities represented by dictionaries containing "name", "population", and "country" keys:

```
cities = [
    {"name": "Mumbai", "population": "19,000,000", "country": "India"},
    {"name": "Calcutta", "population": "15,000,000", "country": "India"},
    {"name": "New York", "population": "20,000,000", "country": "USA"},
    {"name": "Chicago", "population": "7,000,000", "country": "USA"},
    {"name": "Tokyo", "population": "33,000,000", "country": "Japan"},
]
```

...and you'd like to display a hierarchical list that is ordered by country, like this:

- India
 - Mumbai: 19,000,000
 - Calcutta: 15,000,000
- USA
 - New York: 20,000,000
 - Chicago: 7,000,000
- Japan
 - Tokyo: 33,000,000

You can use the `{% regroup %}` tag to group the list of cities by country. The following snippet of template code would accomplish this:

```
{% regroup cities by country as country_list %}

<ul>
{% for country in country_list %}
    <li>{{ country.grouper }}
    <ul>
        {% for city in country.list %}
            <li>{{ city.name }}: {{ city.population }}</li>
        {% endfor %}
    </ul>
</li>
</ul>
```

(continues on next page)

(continued from previous page)

```

    </ul>
  </li>
{% endfor %}
</ul>

```

Let's walk through this example. `{% regroup %}` takes three arguments: the list you want to regroup, the attribute to group by, and the name of the resulting list. Here, we're regrouping the `cities` list by the `country` attribute and calling the result `country_list`.

`{% regroup %}` produces a list (in this case, `country_list`) of group objects. Group objects are instances of `namedtuple()` with two fields:

- `group` – the item that was grouped by (e.g., the string “India” or “Japan”).
- `list` – a list of all items in this group (e.g., a list of all cities with `country='India'`).

Because `{% regroup %}` produces `namedtuple()` objects, you can also write the previous example as:

```

{% regroup cities by country as country_list %}

<ul>
{% for country, local_cities in country_list %}
  <li>{{ country }}
  <ul>
    {% for city in local_cities %}
      <li>{{ city.name }}: {{ city.population }}</li>
    {% endfor %}
  </ul>
</li>
{% endfor %}
</ul>

```

Note that `{% regroup %}` does not order its input! Our example relies on the fact that the `cities` list was ordered by `country` in the first place. If the `cities` list did not order its members by `country`, the regrouping would naively display more than one group for a single country. For example, say the `cities` list was set to this (note that the countries are not grouped together):

```

cities = [
    {"name": "Mumbai", "population": "19,000,000", "country": "India"},
    {"name": "New York", "population": "20,000,000", "country": "USA"},
    {"name": "Calcutta", "population": "15,000,000", "country": "India"},
    {"name": "Chicago", "population": "7,000,000", "country": "USA"},
    {"name": "Tokyo", "population": "33,000,000", "country": "Japan"},
]

```

With this input for `cities`, the example `{% regroup %}` template code above would result in the following

output:

- India
 - Mumbai: 19,000,000
- USA
 - New York: 20,000,000
- India
 - Calcutta: 15,000,000
- USA
 - Chicago: 7,000,000
- Japan
 - Tokyo: 33,000,000

The easiest solution to this gotcha is to make sure in your view code that the data is ordered according to how you want to display it.

Another solution is to sort the data in the template using the `dictsort` filter, if your data is in a list of dictionaries:

```
{% regroup cities|dictsort:"country" by country as country_list %}
```

Grouping on other properties

Any valid template lookup is a legal grouping attribute for the `regroup` tag, including methods, attributes, dictionary keys and list items. For example, if the “country” field is a foreign key to a class with an attribute “description,” you could use:

```
{% regroup cities by country.description as country_list %}
```

Or, if `country` is a field with choices, it will have a `get_FOO_display()` method available as an attribute, allowing you to group on the display string rather than the `choices` key:

```
{% regroup cities by get_country_display as country_list %}
```

`{{ country.grouper }}` will now display the value fields from the `choices` set rather than the keys.

resetcycle

Resets a previous `cycle` so that it restarts from its first item at its next encounter. Without arguments, `{% resetcycle %}` will reset the last `{% cycle %}` defined in the template.

Example usage:

```
{% for coach in coach_list %}
    <h1>{{ coach.name }}</h1>
    {% for athlete in coach.athlete_set.all %}
        <p class="{% cycle 'odd' 'even' %}">{{ athlete.name }}</p>
    {% endfor %}
    {% resetcycle %}
{% endfor %}
```

This example would return this HTML:

```
<h1>Gareth</h1>
<p class="odd">Harry</p>
<p class="even">John</p>
<p class="odd">Nick</p>

<h1>John</h1>
<p class="odd">Andrea</p>
<p class="even">Melissa</p>
```

Notice how the first block ends with `class="odd"` and the new one starts with `class="odd"`. Without the `{% resetcycle %}` tag, the second block would start with `class="even"`.

You can also reset named cycle tags:

```
{% for item in list %}
    <p class="{% cycle 'odd' 'even' as stripe %} {% cycle 'major' 'minor' 'minor' 'minor' 'minor'
    as tick %}">
        {{ item.data }}
    </p>
    {% ifchanged item.category %}
        <h1>{{ item.category }}</h1>
        {% if not forloop.first %}{% resetcycle tick %}{% endif %}
    {% endifchanged %}
{% endfor %}
```

In this example, we have both the alternating odd/even rows and a “major” row every fifth row. Only the five-row cycle is reset when a category changes.

spaceless

Removes whitespace between HTML tags. This includes tab characters and newlines.

Example usage:

```
{% spaceless %}
<p>
    <a href="foo/">Foo</a>
</p>
{% endspaceless %}
```

This example would return this HTML:

```
<p><a href="foo/">Foo</a></p>
```

Only space between tags is removed –not space between tags and text. In this example, the space around Hello won't be stripped:

```
{% spaceless %}
<strong>
    Hello
</strong>
{% endspaceless %}
```

templatetag

Outputs one of the syntax characters used to compose template tags.

The template system has no concept of “escaping” individual characters. However, you can use the `{% templatetag %}` tag to display one of the template tag character combinations.

The argument tells which template bit to output:

Argument	Outputs
openblock	{%
closeblock	%}
openvariable	{{
closevariable	}}
openbrace	{
closebrace	}
opencomment	{#
closecomment	#}

Sample usage:

```
The {% templatetag openblock %} characters open a block.
```

See also the *verbatim* tag for another way of including these characters.

url

Returns an absolute path reference (a URL without the domain name) matching a given view and optional parameters. Any special characters in the resulting path will be encoded using *iri_to_uri()*.

This is a way to output links without violating the DRY principle by having to hard-code URLs in your templates:

```
{% url 'some-url-name' v1 v2 %}
```

The first argument is a [URL pattern name](#). It can be a quoted literal or any other context variable. Additional arguments are optional and should be space-separated values that will be used as arguments in the URL. The example above shows passing positional arguments. Alternatively you may use keyword syntax:

```
{% url 'some-url-name' arg1=v1 arg2=v2 %}
```

Do not mix both positional and keyword syntax in a single call. All arguments required by the URLconf should be present.

For example, suppose you have a view, `app_views.client`, whose URLconf takes a client ID (here, `client()` is a method inside the views file `app_views.py`). The URLconf line might look like this:

```
path("client/<int:id>/", app_views.client, name="app-views-client")
```

If this app's URLconf is included into the project's URLconf under a path such as this:

```
path("clients/", include("project_name.app_name.urls"))
```

...then, in a template, you can create a link to this view like this:

```
{% url 'app-views-client' client.id %}
```

The template tag will output the string `/clients/client/123/`.

Note that if the URL you're reversing doesn't exist, you'll get an *NoReverseMatch* exception raised, which will cause your site to display an error page.

If you'd like to retrieve a URL without displaying it, you can use a slightly different call:

```
{% url 'some-url-name' arg arg2 as the_url %}

<a href="{{ the_url }}">I'm linking to {{ the_url }}</a>
```

The scope of the variable created by the `as var` syntax is the `{% block %}` in which the `{% url %}` tag appears.

This `{% url ... as var %}` syntax will not cause an error if the view is missing. In practice you'll use this to link to views that are optional:

```
{% url 'some-url-name' as the_url %}
{% if the_url %}
    <a href="{{ the_url }}">Link to optional stuff</a>
{% endif %}
```

If you'd like to retrieve a namespaced URL, specify the fully qualified name:

```
{% url 'myapp:view-name' %}
```

This will follow the normal [namespaced URL resolution strategy](#), including using any hints provided by the context as to the current application.

Warning: Don't forget to put quotes around the URL pattern name, otherwise the value will be interpreted as a context variable!

verbatim

Stops the template engine from rendering the contents of this block tag.

A common use is to allow a JavaScript template layer that collides with Django's syntax. For example:

```
{% verbatim %}
    {{if dying}}Still alive.{{/if}}
{% endverbatim %}
```

You can also designate a specific closing tag, allowing the use of `{% endverbatim %}` as part of the unrendered contents:

```
{% verbatim myblock %}
    Avoid template rendering via the {% verbatim %}{% endverbatim %} block.
{% endverbatim myblock %}
```

`widthratio`

For creating bar charts and such, this tag calculates the ratio of a given value to a maximum value, and then applies that ratio to a constant.

For example:

```

```

If `this_value` is 175, `max_value` is 200, and `max_width` is 100, the image in the above example will be 88 pixels wide (because $175/200 = .875$; $.875 * 100 = 87.5$ which is rounded up to 88).

In some cases you might want to capture the result of `widthratio` in a variable. It can be useful, for instance, in a `blocktranslate` like this:

```
{% widthratio this_value max_value max_width as width %}
{% blocktranslate %}The width is: {{ width }}{% endblocktranslate %}
```

`with`

Caches a complex variable under a simpler name. This is useful when accessing an “expensive” method (e.g., one that hits the database) multiple times.

For example:

```
{% with total=business.employees.count %}
    {{ total }} employee{{ total|pluralize }}
{% endwith %}
```

The populated variable (in the example above, `total`) is only available between the `{% with %}` and `{% endwith %}` tags.

You can assign more than one context variable:

```
{% with alpha=1 beta=2 %}
    ...
{% endwith %}
```

Note: The previous more verbose format is still supported: `{% with business.employees.count as total %}`

Built-in filter reference

add

Adds the argument to the value.

For example:

```
{{ value|add:"2" }}
```

If `value` is 4, then the output will be 6.

This filter will first try to coerce both values to integers. If this fails, it'll attempt to add the values together anyway. This will work on some data types (strings, list, etc.) and fail on others. If it fails, the result will be an empty string.

For example, if we have:

```
{{ first|add:second }}
```

and `first` is [1, 2, 3] and `second` is [4, 5, 6], then the output will be [1, 2, 3, 4, 5, 6].

Warning: Strings that can be coerced to integers will be summed, not concatenated, as in the first example above.

addslashes

Adds slashes before quotes. Useful for escaping strings in CSV, for example.

For example:

```
{{ value|addslashes }}
```

If `value` is "I'm using Django", the output will be "I\'m using Django".

capfirst

Capitalizes the first character of the value. If the first character is not a letter, this filter has no effect.

For example:

```
{{ value|capfirst }}
```

If `value` is "django", the output will be "Django".

center

Centers the value in a field of a given width.

For example:

```
"{{ value|center:"15" }}"
```

If value is "Django", the output will be " Django ".

cut

Removes all values of arg from the given string.

For example:

```
{{ value|cut:" " }}
```

If value is "String with spaces", the output will be "Stringwithspaces".

date

Formats a date according to the given format.

Uses a similar format to PHP's `date()` function with some differences.

Note: These format characters are not used in Django outside of templates. They were designed to be compatible with PHP to ease transitioning for designers.

Available format strings:

Format character	Description
Day	
d	Day of the month, 2 digits with leading zeros.
j	Day of the month without leading zeros.
D	Day of the week, textual, 3 letters.
l	Day of the week, textual, long.
S	English ordinal suffix for day of the month, 2 characters.
w	Day of the week, digits without leading zeros.
z	Day of the year.
Week	

Format character	Description
W	ISO-8601 week number of year, with weeks starting on Monday.
Month	
m	Month, 2 digits with leading zeros.
n	Month without leading zeros.
M	Month, textual, 3 letters.
b	Month, textual, 3 letters, lowercase.
E	Month, locale specific alternative representation usually used for long date representation.
F	Month, textual, long.
N	Month abbreviation in Associated Press style. Proprietary extension.
t	Number of days in the given month.
Year	
y	Year, 2 digits with leading zeros.
Y	Year, 4 digits with leading zeros.
L	Boolean for whether it's a leap year.
o	ISO-8601 week-numbering year, corresponding to the ISO-8601 week number (W) which uses leap weeks.
Time	
g	Hour, 12-hour format without leading zeros.
G	Hour, 24-hour format without leading zeros.
h	Hour, 12-hour format.
H	Hour, 24-hour format.
i	Minutes.
s	Seconds, 2 digits with leading zeros.
u	Microseconds.
a	'a.m.' or 'p.m.' (Note that this is slightly different than PHP's output, because this includes periods)
A	'AM' or 'PM'.
f	Time, in 12-hour hours and minutes, with minutes left off if they're zero. Proprietary extension.
P	Time, in 12-hour hours, minutes and 'a.m.' / 'p.m.', with minutes left off if they're zero and the s
Timezone	
e	Timezone name. Could be in any format, or might return an empty string, depending on the datetime.
I	Daylight saving time, whether it's in effect or not.
O	Difference to Greenwich time in hours.
T	Time zone of this machine.
Z	Time zone offset in seconds. The offset for timezones west of UTC is always negative, and for those east
Date/Time	
c	ISO 8601 format. (Note: unlike other formatters, such as "Z", "O" or "r", the "c" formatter will
r	RFC 5322 formatted date.
U	Seconds since the Unix Epoch (January 1 1970 00:00:00 UTC).

For example:

```
{{ value|date:"D d M Y" }}
```

If `value` is a `datetime` object (e.g., the result of `datetime.datetime.now()`), the output will be the string `'Wed 09 Jan 2008'`.

The format passed can be one of the predefined ones `DATE_FORMAT`, `DATETIME_FORMAT`, `SHORT_DATE_FORMAT` or `SHORT_DATETIME_FORMAT`, or a custom format that uses the format specifiers shown in the table above. Note that predefined formats may vary depending on the current locale.

Assuming that `USE_L10N` is `True` and `LANGUAGE_CODE` is, for example, `"es"`, then for:

```
{{ value|date:"SHORT_DATE_FORMAT" }}
```

the output would be the string `"09/01/2008"` (the `"SHORT_DATE_FORMAT"` format specifier for the `es` locale as shipped with Django is `"d/m/Y"`).

When used without a format string, the `DATE_FORMAT` format specifier is used. Assuming the same settings as the previous example:

```
{{ value|date }}
```

outputs `9 de Enero de 2008` (the `DATE_FORMAT` format specifier for the `es` locale is `r'j \d\e F \d\e Y'`). Both `"d"` and `"e"` are backslash-escaped, because otherwise each is a format string that displays the day and the timezone name, respectively.

You can combine `date` with the `time` filter to render a full representation of a `datetime` value. E.g.:

```
{{ value|date:"D d M Y" }} {{ value|time:"H:i" }}
```

default

If `value` evaluates to `False`, uses the given default. Otherwise, uses the value.

For example:

```
{{ value|default:"nothing" }}
```

If `value` is `""` (the empty string), the output will be `nothing`.

default_if_none

If (and only if) value is `None`, uses the given default. Otherwise, uses the value.

Note that if an empty string is given, the default value will not be used. Use the `default` filter if you want to fallback for empty strings.

For example:

```
{{ value|default_if_none:"nothing" }}
```

If `value` is `None`, the output will be `nothing`.

dictsort

Takes a list of dictionaries and returns that list sorted by the key given in the argument.

For example:

```
{{ value|dictsort:"name" }}
```

If `value` is:

```
[
    {"name": "zed", "age": 19},
    {"name": "amy", "age": 22},
    {"name": "joe", "age": 31},
]
```

then the output would be:

```
[
    {"name": "amy", "age": 22},
    {"name": "joe", "age": 31},
    {"name": "zed", "age": 19},
]
```

You can also do more complicated things like:

```
{% for book in books|dictsort:"author.age" %}
    * {{ book.title }} ({{ book.author.name }})
{% endfor %}
```

If `books` is:

```
[
    {"title": "1984", "author": {"name": "George", "age": 45}},
    {"title": "Timequake", "author": {"name": "Kurt", "age": 75}},
    {"title": "Alice", "author": {"name": "Lewis", "age": 33}},
]
```

then the output would be:

```
* Alice (Lewis)
* 1984 (George)
* Timequake (Kurt)
```

`dictsort` can also order a list of lists (or any other object implementing `__getitem__()`) by elements at specified index. For example:

```
{{ value|dictsort:0 }}
```

If `value` is:

```
[
    ("a", "42"),
    ("c", "string"),
    ("b", "foo"),
]
```

then the output would be:

```
[
    ("a", "42"),
    ("b", "foo"),
    ("c", "string"),
]
```

You must pass the index as an integer rather than a string. The following produce empty output:

```
{{ values|dictsort:"0" }}
```

Ordering by elements at specified index is not supported on dictionaries.

In older versions, ordering elements at specified index was supported on dictionaries.

`dictsortreversed`

Takes a list of dictionaries and returns that list sorted in reverse order by the key given in the argument. This works exactly the same as the above filter, but the returned value will be in reverse order.

`divisibleby`

Returns `True` if the value is divisible by the argument.

For example:

```
{{ value|divisibleby:"3" }}
```

If `value` is 21, the output would be `True`.

`escape`

Escapes a string's HTML. Specifically, it makes these replacements:

- `<` is converted to `<`;
- `>` is converted to `>`;
- `'` (single quote) is converted to `'`;
- `"` (double quote) is converted to `"`;
- `&` is converted to `&`;

Applying `escape` to a variable that would normally have auto-escaping applied to the result will only result in one round of escaping being done. So it is safe to use this function even in auto-escaping environments. If you want multiple escaping passes to be applied, use the `force_escape` filter.

For example, you can apply `escape` to fields when `autoescape` is off:

```
{% autoescape off %}
  {{ title|escape }}
{% endautoescape %}
```

Chaining `escape` with other filters

As mentioned in the `autoescape` section, when filters including `escape` are chained together, it can result in unexpected outcomes if preceding filters mark a potentially unsafe string as safe due to the lack of escaping caused by `autoescape` being off.

In such cases, chaining `escape` would not reescape strings that have already been marked as safe.

`escapejs`

Escapes characters for use as a whole JavaScript string literal, within single or double quotes, as below. This filter does not make the string safe for use in “JavaScript template literals” (the JavaScript backtick syntax). Any other uses not listed above are not supported. It is generally recommended that data should be passed using HTML `data-` attributes, or the `json_script` filter, rather than in embedded JavaScript.

For example:

```
<script>
let myValue = '{{ value|escapejs }}'
```

`filesizeformat`

Formats the value like a ‘human-readable’ file size (i.e. '13 KB', '4.1 MB', '102 bytes', etc.).

For example:

```
{{ value|filesizeformat }}
```

If `value` is 123456789, the output would be 117.7 MB.

File sizes and SI units

Strictly speaking, `filesizeformat` does not conform to the International System of Units which recommends using KiB, MiB, GiB, etc. when byte sizes are calculated in powers of 1024 (which is the case here). Instead, Django uses traditional unit names (KB, MB, GB, etc.) corresponding to names that are more commonly used.

`first`

Returns the first item in a list.

For example:

```
{{ value|first }}
```

If `value` is the list ['a', 'b', 'c'], the output will be 'a'.

`floatformat`

When used without an argument, rounds a floating-point number to one decimal place –but only if there’s a decimal part to be displayed. For example:

value	Template	Output
34.23234	<code>{{ value floatformat }}</code>	34.2
34.00000	<code>{{ value floatformat }}</code>	34
34.26000	<code>{{ value floatformat }}</code>	34.3

If used with a numeric integer argument, `floatformat` rounds a number to that many decimal places. For example:

value	Template	Output
34.23234	<code>{{ value floatformat:3 }}</code>	34.232
34.00000	<code>{{ value floatformat:3 }}</code>	34.000
34.26000	<code>{{ value floatformat:3 }}</code>	34.260

Particularly useful is passing 0 (zero) as the argument which will round the float to the nearest integer.

value	Template	Output
34.23234	<code>{{ value floatformat:"0" }}</code>	34
34.00000	<code>{{ value floatformat:"0" }}</code>	34
39.56000	<code>{{ value floatformat:"0" }}</code>	40

If the argument passed to `floatformat` is negative, it will round a number to that many decimal places –but only if there’s a decimal part to be displayed. For example:

value	Template	Output
34.23234	<code>{{ value floatformat:"-3" }}</code>	34.232
34.00000	<code>{{ value floatformat:"-3" }}</code>	34
34.26000	<code>{{ value floatformat:"-3" }}</code>	34.260

If the argument passed to `floatformat` has the `g` suffix, it will force grouping by the `THOUSAND_SEPARATOR` for the active locale. For example, when the active locale is `en` (English):

value	Template	Output
34232.34	<code>{{ value floatformat:"2g" }}</code>	34,232.34
34232.06	<code>{{ value floatformat:"g" }}</code>	34,232.1
34232.00	<code>{{ value floatformat:"-3g" }}</code>	34,232

Output is always localized (independently of the `{% localize off %}` tag) unless the argument passed to `floatformat` has the `u` suffix, which will force disabling localization. For example, when the active locale is `pl` (Polish):

value	Template	Output
34.23234	<code>{{ value floatformat:"3" }}</code>	34,232
34.23234	<code>{{ value floatformat:"3u" }}</code>	34.232

Using `floatformat` with no argument is equivalent to using `floatformat` with an argument of `-1`.

`force_escape`

Applies HTML escaping to a string (see the `escape` filter for details). This filter is applied immediately and returns a new, escaped string. This is useful in the rare cases where you need multiple escaping or want to apply other filters to the escaped results. Normally, you want to use the `escape` filter.

For example, if you want to catch the `<p>` HTML elements created by the `linebreaks` filter:

```
{% autoescape off %}
    {{ body|linebreaks|force_escape }}
{% endautoescape %}
```

`get_digit`

Given a whole number, returns the requested digit, where 1 is the right-most digit, 2 is the second-right-most digit, etc. Returns the original value for invalid input (if input or argument is not an integer, or if argument is less than 1). Otherwise, output is always an integer.

For example:

```
{{ value|get_digit:"2" }}
```

If `value` is 123456789, the output will be 8.

`iriencode`

Converts an IRI (Internationalized Resource Identifier) to a string that is suitable for including in a URL. This is necessary if you’re trying to use strings containing non-ASCII characters in a URL.

It’s safe to use this filter on a string that has already gone through the `urlencode` filter.

For example:

```
{{ value|iriencode }}
```

If value is `"?test=1&me=2"`, the output will be `"?test=1&me=2"`.

`join`

Joins a list with a string, like Python’s `str.join(list)`

For example:

```
{{ value|join:" // " }}
```

If value is the list `['a', 'b', 'c']`, the output will be the string `"a // b // c"`.

`json_script`

Safely outputs a Python object as JSON, wrapped in a `<script>` tag, ready for use with JavaScript.

Argument: The optional HTML “id” of the `<script>` tag.

For example:

```
{{ value|json_script:"hello-data" }}
```

If value is the dictionary `{'hello': 'world'}`, the output will be:

```
<script id="hello-data" type="application/json">{"hello": "world"}</script>
```

The resulting data can be accessed in JavaScript like this:

```
const value = JSON.parse(document.getElementById('hello-data').textContent);
```

XSS attacks are mitigated by escaping the characters “<”, “>” and “&”. For example if value is `{'hello': 'world</script>&';}`, the output is:

```
<script id="hello-data" type="application/json">{"hello": "world\\u003C/script\\u003E\\u0026amp;"}↵</script>
```

This is compatible with a strict Content Security Policy that prohibits in-page script execution. It also maintains a clean separation between passive data and executable code.

In older versions, the HTML “id” was a required argument.

`last`

Returns the last item in a list.

For example:

```
{{ value|last }}
```

If `value` is the list `['a', 'b', 'c', 'd']`, the output will be the string `"d"`.

`length`

Returns the length of the value. This works for both strings and lists.

For example:

```
{{ value|length }}
```

If `value` is `['a', 'b', 'c', 'd']` or `"abcd"`, the output will be `4`.

The filter returns `0` for an undefined variable.

`length_is`

Deprecated since version 4.2.

Returns `True` if the value's length is the argument, or `False` otherwise.

For example:

```
{{ value|length_is:"4" }}
```

If `value` is `['a', 'b', 'c', 'd']` or `"abcd"`, the output will be `True`.

linebreaks

Replaces line breaks in plain text with appropriate HTML; a single newline becomes an HTML line break (`<br>`) and a new line followed by a blank line becomes a paragraph break (`</p>`).

For example:

```
{{ value|linebreaks }}
```

If value is `Joel\nis a slug`, the output will be `<p>Joel<br>is a slug</p>`.

linebreaksbr

Converts all newlines in a piece of plain text to HTML line breaks (`<br>`).

For example:

```
{{ value|linebreaksbr }}
```

If value is `Joel\nis a slug`, the output will be `Joel<br>is a slug`.

linenumbers

Displays text with line numbers.

For example:

```
{{ value|linenumbers }}
```

If value is:

```
one
two
three
```

the output will be:

```
1. one
2. two
3. three
```

`ljust`

Left-aligns the value in a field of a given width.

Argument: field size

For example:

```
"{{ value|ljust:"10" }}"
```

If `value` is `Django`, the output will be `"Django "`.

`lower`

Converts a string into all lowercase.

For example:

```
{{ value|lower }}
```

If `value` is `Totally LOVING this Album!`, the output will be `totally loving this album!`.

`make_list`

Returns the value turned into a list. For a string, it's a list of characters. For an integer, the argument is cast to a string before creating a list.

For example:

```
{{ value|make_list }}
```

If `value` is the string `"Joel"`, the output would be the list `['J', 'o', 'e', 'l']`. If `value` is `123`, the output will be the list `['1', '2', '3']`.

`phone2numeric`

Converts a phone number (possibly containing letters) to its numerical equivalent.

The input doesn't have to be a valid phone number. This will happily convert any string.

For example:

```
{{ value|phone2numeric }}
```

If `value` is `800-COLLECT`, the output will be `800-2655328`.

pluralize

Returns a plural suffix if the value is not 1, '1', or an object of length 1. By default, this suffix is 's'.

Example:

```
You have {{ num_messages }} message{{ num_messages|pluralize }}.
```

If `num_messages` is 1, the output will be `You have 1 message.` If `num_messages` is 2 the output will be `You have 2 messages.`

For words that require a suffix other than 's', you can provide an alternate suffix as a parameter to the filter.

Example:

```
You have {{ num_walruses }} walrus{{ num_walruses|pluralize:"es" }}.
```

For words that don't pluralize by simple suffix, you can specify both a singular and plural suffix, separated by a comma.

Example:

```
You have {{ num_cherries }} cherr{{ num_cherries|pluralize:"y,ies" }}.
```

Note: Use *blocktranslate* to pluralize translated strings.

pprint

A wrapper around `pprint.pprint()` –for debugging, really.

random

Returns a random item from the given list.

For example:

```
{{ value|random }}
```

If `value` is the list `['a', 'b', 'c', 'd']`, the output could be `"b"`.

`rjust`

Right-aligns the value in a field of a given width.

Argument: field size

For example:

```
"{{ value|rjust:"10" }}"
```

If `value` is `Django`, the output will be " `Django`".

`safe`

Marks a string as not requiring further HTML escaping prior to output. When autoescaping is off, this filter has no effect.

Note: If you are chaining filters, a filter applied after `safe` can make the contents unsafe again. For example, the following code prints the variable as is, unescaped:

```
"{{ var|safe|escape }}"
```

`safeseq`

Applies the `safe` filter to each element of a sequence. Useful in conjunction with other filters that operate on sequences, such as `join`. For example:

```
"{{ some_list|safeseq|join:', ' }}"
```

You couldn't use the `safe` filter directly in this case, as it would first convert the variable into a string, rather than working with the individual elements of the sequence.

`slice`

Returns a slice of the list.

Uses the same syntax as Python's list slicing. See <https://diveinto.org/python3/native-datatypes.html#slicinglists> for an introduction.

Example:

```
{{ some_list|slice:"2" }}
```

If `some_list` is `['a', 'b', 'c']`, the output will be `['a', 'b']`.

`slugify`

Converts to ASCII. Converts spaces to hyphens. Removes characters that aren't alphanumerics, underscores, or hyphens. Converts to lowercase. Also strips leading and trailing whitespace.

For example:

```
{{ value|slugify }}
```

If `value` is `"Joel is a slug"`, the output will be `"joel-is-a-slug"`.

`stringformat`

Formats the variable according to the argument, a string formatting specifier. This specifier uses the `printf`-style `String Formatting` syntax, with the exception that the leading `"%"` is dropped.

For example:

```
{{ value|stringformat:"E" }}
```

If `value` is `10`, the output will be `1.000000E+01`.

`striptags`

Makes all possible efforts to strip all `[X]HTML` tags.

For example:

```
{{ value|striptags }}
```

If `value` is `"<b>Joel</b> <button>is</button> a <span>slug</span>"`, the output will be `"Joel is a slug"`.

No safety guarantee

Note that `striptags` doesn't give any guarantee about its output being HTML safe, particularly with non valid HTML input. So NEVER apply the `safe` filter to a `striptags` output. If you are looking for something more robust, consider using a third-party HTML sanitizing tool.

`time`

Formats a time according to the given format.

Given format can be the predefined one `TIME_FORMAT`, or a custom format, same as the `date` filter. Note that the predefined format is locale-dependent.

For example:

```
{{ value|time:"H:i" }}
```

If `value` is equivalent to `datetime.datetime.now()`, the output will be the string "01:23".

Note that you can backslash-escape a format string if you want to use the “raw” value. In this example, both “h” and “m” are backslash-escaped, because otherwise each is a format string that displays the hour and the month, respectively:

```
{{ value|time:"H\\h i\\m" }}
```

This would display as “01h 23m” .

Another example:

Assuming that `USE_L10N` is `True` and `LANGUAGE_CODE` is, for example, “de”, then for:

```
{{ value|time:"TIME_FORMAT" }}
```

the output will be the string "01:23" (The “TIME_FORMAT” format specifier for the `de` locale as shipped with Django is “H:i”).

The `time` filter will only accept parameters in the format string that relate to the time of day, not the date. If you need to format a `date` value, use the `date` filter instead (or along with `time` if you need to render a full `datetime` value).

There is one exception the above rule: When passed a `datetime` value with attached timezone information (a `time-zone-aware datetime` instance) the `time` filter will accept the timezone-related format specifiers ‘e’, ‘O’, ‘T’ and ‘Z’.

When used without a format string, the `TIME_FORMAT` format specifier is used:

```
{{ value|time }}
```

is the same as:

```
{{ value|time:"TIME_FORMAT" }}
```

`timesince`

Formats a date as the time since that date (e.g., “4 days, 6 hours”).

Takes an optional argument that is a variable containing the date to use as the comparison point (without the argument, the comparison point is now). For example, if `blog_date` is a date instance representing midnight on 1 June 2006, and `comment_date` is a date instance for 08:00 on 1 June 2006, then the following would return “8 hours” :

```
{{ blog_date|timesince:comment_date }}
```

Comparing offset-naive and offset-aware datetimes will return an empty string.

Minutes is the smallest unit used, and “0 minutes” will be returned for any date that is in the future relative to the comparison point.

`timeuntil`

Similar to `timesince`, except that it measures the time from now until the given date or datetime. For example, if today is 1 June 2006 and `conference_date` is a date instance holding 29 June 2006, then `{{ conference_date|timeuntil }}` will return “4 weeks” .

Takes an optional argument that is a variable containing the date to use as the comparison point (instead of now). If `from_date` contains 22 June 2006, then the following will return “1 week” :

```
{{ conference_date|timeuntil:from_date }}
```

Comparing offset-naive and offset-aware datetimes will return an empty string.

Minutes is the smallest unit used, and “0 minutes” will be returned for any date that is in the past relative to the comparison point.

`title`

Converts a string into titlecase by making words start with an uppercase character and the remaining characters lowercase. This tag makes no effort to keep “trivial words” in lowercase.

For example:

```
{{ value|title }}
```

If `value` is “my FIRST post”, the output will be “My First Post”.

`truncatechars`

Truncates a string if it is longer than the specified number of characters. Truncated strings will end with a translatable ellipsis character (" ...").

Argument: Number of characters to truncate to

For example:

```
{{ value|truncatechars:7 }}
```

If value is "Joel is a slug", the output will be "Joel i...".

`truncatechars_html`

Similar to `truncatechars`, except that it is aware of HTML tags. Any tags that are opened in the string and not closed before the truncation point are closed immediately after the truncation.

For example:

```
{{ value|truncatechars_html:7 }}
```

If value is "<p>Joel is a slug</p>", the output will be "<p>Joel i...</p>".

Newlines in the HTML content will be preserved.

`truncatewords`

Truncates a string after a certain number of words.

Argument: Number of words to truncate after

For example:

```
{{ value|truncatewords:2 }}
```

If value is "Joel is a slug", the output will be "Joel is ...".

Newlines within the string will be removed.

`truncatewords_html`

Similar to `truncatewords`, except that it is aware of HTML tags. Any tags that are opened in the string and not closed before the truncation point, are closed immediately after the truncation.

This is less efficient than `truncatewords`, so should only be used when it is being passed HTML text.

For example:

```
{{ value|truncatewords_html:2 }}
```

If value is "`<p>Joel is a slug</p>`", the output will be "`<p>Joel is ...</p>`".

Newlines in the HTML content will be preserved.

`unordered_list`

Recursively takes a self-nested list and returns an HTML unordered list –WITHOUT opening and closing `<ul>` tags.

The list is assumed to be in the proper format. For example, if `var` contains `['States', ['Kansas', ['Lawrence', 'Topeka'], 'Illinois']]`, then `{{ var|unordered_list }}` would return:

```
<li>States
<ul>
    <li>Kansas
    <ul>
        <li>Lawrence</li>
        <li>Topeka</li>
    </ul>
    </li>
    <li>Illinois</li>
</ul>
</li>
```

`upper`

Converts a string into all uppercase.

For example:

```
{{ value|upper }}
```

If value is "`Joel is a slug`", the output will be "`JOEL IS A SLUG`".

urlencode

Escapes a value for use in a URL.

For example:

```
{{ value|urlencode }}
```

If value is "https://www.example.org/foo?a=b&c=d", the output will be "https%3A//www.example.org/foo%3Fa%3Db%26c%3Dd".

An optional argument containing the characters which should not be escaped can be provided.

If not provided, the `'` character is assumed safe. An empty string can be provided when all characters should be escaped. For example:

```
{{ value|urlencode:"" }}
```

If value is "https://www.example.org/", the output will be "https%3A%2F%2Fwww.example.org%2F".

urlize

Converts URLs and email addresses in text into clickable links.

This template tag works on links prefixed with `http://`, `https://`, or `www..` For example, `https://goo.gl/aiaIt` will get converted but `goo.gl/aiaIt` won't.

It also supports domain-only links ending in one of the original top level domains (`.com`, `.edu`, `.gov`, `.int`, `.mil`, `.net`, and `.org`). For example, `django project.com` gets converted.

Links can have trailing punctuation (periods, commas, close-parens) and leading punctuation (opening parens), and `urlize` will still do the right thing.

Links generated by `urlize` have a `rel="nofollow"` attribute added to them.

For example:

```
{{ value|urlize }}
```

If value is "Check out `www.django project.com`", the output will be "Check out `<a href="http://www.django project.com" rel="nofollow">www.django project.com</a>`".

In addition to web links, `urlize` also converts email addresses into `mailto:` links. If value is "Send questions to `foo@example.com`", the output will be "Send questions to `<a href="mailto:foo@example.com">foo@example.com</a>`".

The `urlize` filter also takes an optional parameter `autoescape`. If `autoescape` is `True`, the link text and URLs will be escaped using Django's built-in `escape` filter. The default value for `autoescape` is `True`.

Note: If `urlize` is applied to text that already contains HTML markup, or to email addresses that contain single quotes ('), things won't work as expected. Apply this filter only to plain text.

`urlizetrunc`

Converts URLs and email addresses into clickable links just like `urlize`, but truncates URLs longer than the given character limit.

Argument: Number of characters that link text should be truncated to, including the ellipsis that's added if truncation is necessary.

For example:

```
{{ value|urlizetrunc:15 }}
```

If value is "Check out `www.djangoproject.com`", the output would be 'Check out www.djangoproj...'.

As with `urlize`, this filter should only be applied to plain text.

`wordcount`

Returns the number of words.

For example:

```
{{ value|wordcount }}
```

If value is "Joel is a slug", the output will be 4.

`wordwrap`

Wraps words at specified line length.

Argument: number of characters at which to wrap the text

For example:

```
{{ value|wordwrap:5 }}
```

If value is "Joel is a slug", the output would be:

```
Joel
is a
slug
```

yesno

Maps values for `True`, `False`, and (optionally) `None`, to the strings “yes”, “no”, “maybe”, or a custom mapping passed as a comma-separated list, and returns one of those strings according to the value:

For example:

```
{{ value|yesno:"yeah,no,maybe" }}
```

Value	Argument	Outputs
<code>True</code>		yes
<code>True</code>	<code>"yeah,no,maybe"</code>	yeah
<code>False</code>	<code>"yeah,no,maybe"</code>	no
<code>None</code>	<code>"yeah,no,maybe"</code>	maybe
<code>None</code>	<code>"yeah,no"</code>	no (converts <code>None</code> to <code>False</code> if no mapping for <code>None</code> is given)

Internationalization tags and filters

Django provides template tags and filters to control each aspect of [internationalization](#) in templates. They allow for granular control of translations, formatting, and time zone conversions.

i18n

This library allows specifying translatable text in templates. To enable it, set `USE_I18N` to `True`, then load it with `{% load i18n %}`.

See [Internationalization: in template code](#).

l10n

This library provides control over the localization of values in templates. You only need to load the library using `{% load l10n %}`, but you’ll often set `USE_L10N` to `True` so that localization is active by default.

See [Controlling localization in templates](#).

`tz`

This library provides control over time zone conversions in templates. Like `l10n`, you only need to load the library using `{% load tz %}`, but you'll usually also set `USE_TZ` to `True` so that conversion to local time happens by default.

See [Time zone aware output in templates](#).

Other tags and filters libraries

Django comes with a couple of other template-tag libraries that you have to enable explicitly in your `INSTALLED_APPS` setting and enable in your template with the `{% load %}` tag.

`django.contrib.humanize`

A set of Django template filters useful for adding a “human touch” to data. See [django.contrib.humanize](#).

`static`

`static`

To link to static files that are saved in `STATIC_ROOT` Django ships with a `static` template tag. If the `django.contrib.staticfiles` app is installed, the tag will serve files using `url()` method of the storage specified by `staticfiles` in `STORAGES`. For example:

```
{% load static %}

```

It is also able to consume standard context variables, e.g. assuming a `user_stylesheet` variable is passed to the template:

```
{% load static %}
<link rel="stylesheet" href="{% static user_stylesheet %}" media="screen">
```

If you'd like to retrieve a static URL without displaying it, you can use a slightly different call:

```
{% load static %}
{% static "images/hi.jpg" as myphoto %}

```

Using Jinja2 templates?

See *Jinja2* for information on using the `static` tag with Jinja2.

`get_static_prefix`

You should prefer the `static` template tag, but if you need more control over exactly where and how `STATIC_URL` is injected into the template, you can use the `get_static_prefix` template tag:

```
{% load static %}

```

There's also a second form you can use to avoid extra processing if you need the value multiple times:

```
{% load static %}
{% get_static_prefix as STATIC_PREFIX %}

```

`get_media_prefix`

Similar to the `get_static_prefix`, `get_media_prefix` populates a template variable with the media prefix `MEDIA_URL`, e.g.:

```
{% load static %}
<body data-media-url="{% get_media_prefix %}">
```

By storing the value in a data attribute, we ensure it's escaped appropriately if we want to use it in a JavaScript context.

6.22.3 The Django template language: for Python programmers

This document explains the Django template system from a technical perspective –how it works and how to extend it. If you're looking for reference on the language syntax, see [The Django template language](#).

It assumes an understanding of templates, contexts, variables, tags, and rendering. Start with the [introduction to the Django template language](#) if you aren't familiar with these concepts.

Overview

Using the template system in Python is a three-step process:

1. You configure an *Engine*.
2. You compile template code into a *Template*.
3. You render the template with a *Context*.

Django projects generally rely on the high level, backend agnostic APIs for each of these steps instead of the template system's lower level APIs:

1. For each *DjangoTemplates* backend in the *TEMPLATES* setting, Django instantiates an *Engine*. *DjangoTemplates* wraps *Engine* and adapts it to the common template backend API.
2. The *django.template.loader* module provides functions such as *get_template()* for loading templates. They return a *django.template.backends.django.Template* which wraps the actual *django.template.Template*.
3. The *Template* obtained in the previous step has a *render()* method which marshals a context and possibly a request into a *Context* and delegates the rendering to the underlying *Template*.

Configuring an engine

If you are using the *DjangoTemplates* backend, this probably isn't the documentation you're looking for. An instance of the *Engine* class described below is accessible using the *engine* attribute of that backend and any attribute defaults mentioned below are overridden by what's passed by *DjangoTemplates*.

```
class Engine(dirs=None, app_dirs=False, context_processors=None, debug=False, loaders=None,
             string_if_invalid='', file_charset='utf-8', libraries=None, builtins=None,
             autoescape=True)
```

When instantiating an *Engine* all arguments must be passed as keyword arguments:

- *dirs* is a list of directories where the engine should look for template source files. It is used to configure *filesystem.Loader*.

It defaults to an empty list.

- *app_dirs* only affects the default value of *loaders*. See below.

It defaults to *False*.

- *autoescape* controls whether HTML autoescaping is enabled.

It defaults to *True*.

Warning: Only set it to *False* if you're rendering non-HTML templates!

- `context_processors` is a list of dotted Python paths to callables that are used to populate the context when a template is rendered with a request. These callables take a request object as their argument and return a `dict` of items to be merged into the context.

It defaults to an empty list.

See [RequestContext](#) for more information.

- `debug` is a boolean that turns on/off template debug mode. If it is `True`, the template engine will store additional debug information which can be used to display a detailed report for any exception raised during template rendering.

It defaults to `False`.

- `loaders` is a list of template loader classes, specified as strings. Each `Loader` class knows how to import templates from a particular source. Optionally, a tuple can be used instead of a string. The first item in the tuple should be the `Loader` class name, subsequent items are passed to the `Loader` during initialization.

It defaults to a list containing:

- `'django.template.loaders.filesystem.Loader'`
- `'django.template.loaders.app_directories.Loader'` if and only if `app_dirs` is `True`.

These loaders are then wrapped in [django.template.loaders.cached.Loader](#).

In older versions, the cached template loader was only enabled by default when `DEBUG` was `False`.

See [Loader types](#) for details.

- `string_if_invalid` is the output, as a string, that the template system should use for invalid (e.g. misspelled) variables.

It defaults to the empty string.

See [How invalid variables are handled](#) for details.

- `file_charset` is the charset used to read template files on disk.

It defaults to `'utf-8'`.

- `'libraries'`: A dictionary of labels and dotted Python paths of template tag modules to register with the template engine. This is used to add new libraries or provide alternate labels for existing ones. For example:

```
Engine(  
    libraries={  
        "myapp_tags": "path.to.myapp.tags",  
        "admin.urls": "django.contrib.admin templatetags.admin_urls",  
    },  
)
```

Libraries can be loaded by passing the corresponding dictionary key to the `{% load %}` tag.

- 'builtins': A list of dotted Python paths of template tag modules to add to `built-ins`. For example:

```
Engine(  
    builtins=["myapp.builtins"],  
)
```

Tags and filters from built-in libraries can be used without first calling the `{% load %}` tag.

static `Engine.get_default()`

Returns the underlying *Engine* from the first configured *DjangoTemplates* engine. Raises *ImproperlyConfigured* if no engines are configured.

It's required for preserving APIs that rely on a globally available, implicitly configured engine. Any other use is strongly discouraged.

`Engine.from_string(template_code)`

Compiles the given template code and returns a *Template* object.

`Engine.get_template(template_name)`

Loads a template with the given name, compiles it and returns a *Template* object.

`Engine.select_template(template_name_list)`

Like `get_template()`, except it takes a list of names and returns the first template that was found.

Loading a template

The recommended way to create a *Template* is by calling the factory methods of the *Engine*: `get_template()`, `select_template()` and `from_string()`.

In a Django project where the `TEMPLATES` setting defines a *DjangoTemplates* engine, it's possible to instantiate a *Template* directly. If more than one *DjangoTemplates* engine is defined, the first one will be used.

class `Template`

This class lives at `django.template.Template`. The constructor takes one argument —the raw template code:

```
from django.template import Template  
  
template = Template("My name is {{ my_name }}.")
```

Behind the scenes

The system only parses your raw template code once –when you create the `Template` object. From then on, it’s stored internally as a tree structure for performance.

Even the parsing itself is quite fast. Most of the parsing happens via a single call to a single, short, regular expression.

Rendering a context

Once you have a compiled `Template` object, you can render a context with it. You can reuse the same template to render it several times with different contexts.

`class Context(dict_=None)`

The constructor of `django.template.Context` takes an optional argument —a dictionary mapping variable names to variable values.

For details, see [Playing with Context objects](#) below.

`Template.render(context)`

Call the `Template` object’s `render()` method with a `Context` to “fill” the template:

```
>>> from django.template import Context, Template
>>> template = Template("My name is {{ my_name }}.")

>>> context = Context({"my_name": "Adrian"})
>>> template.render(context)
"My name is Adrian."

>>> context = Context({"my_name": "Dolores"})
>>> template.render(context)
"My name is Dolores."
```

Variables and lookups

Variable names must consist of any letter (A-Z), any digit (0-9), an underscore (but they must not start with an underscore) or a dot.

Dots have a special meaning in template rendering. A dot in a variable name signifies a lookup. Specifically, when the template system encounters a dot in a variable name, it tries the following lookups, in this order:

- Dictionary lookup. Example: `foo["bar"]`
- Attribute lookup. Example: `foo.bar`
- List-index lookup. Example: `foo[bar]`

Note that “bar” in a template expression like `{{ foo.bar }}` will be interpreted as a literal string and not using the value of the variable “bar”, if one exists in the template context.

The template system uses the first lookup type that works. It’s short-circuit logic. Here are a few examples:

```
>>> from django.template import Context, Template
>>> t = Template("My name is {{ person.first_name }}.")
>>> d = {"person": {"first_name": "Joe", "last_name": "Johnson"}}
>>> t.render(Context(d))
"My name is Joe."

>>> class PersonClass:
...     pass
...
>>> p = PersonClass()
>>> p.first_name = "Ron"
>>> p.last_name = "Nasty"
>>> t.render(Context({"person": p}))
"My name is Ron."

>>> t = Template("The first stooge in the list is {{ stooges.0 }}.")
>>> c = Context({"stooges": ["Larry", "Curly", "Moe"]})
>>> t.render(c)
"The first stooge in the list is Larry."
```

If any part of the variable is callable, the template system will try calling it. Example:

```
>>> class PersonClass2:
...     def name(self):
...         return "Samantha"
...
>>> t = Template("My name is {{ person.name }}.")
>>> t.render(Context({"person": PersonClass2}))
"My name is Samantha."
```

Callable variables are slightly more complex than variables which only require straight lookups. Here are some things to keep in mind:

- If the variable raises an exception when called, the exception will be propagated, unless the exception has an attribute `silent_variable_failure` whose value is `True`. If the exception does have a `silent_variable_failure` attribute whose value is `True`, the variable will render as the value of the engine’s `string_if_invalid` configuration option (an empty string, by default). Example:

```
>>> t = Template("My name is {{ person.first_name }}.")
>>> class PersonClass3:
...     def first_name(self):
```

(continues on next page)

(continued from previous page)

```

...         raise AssertionError("foo")
...
>>> p = PersonClass3()
>>> t.render(Context({"person": p}))
Traceback (most recent call last):
...
AssertionError: foo

>>> class SilentAssertionError(Exception):
...     silent_variable_failure = True
...
>>> class PersonClass4:
...     def first_name(self):
...         raise SilentAssertionError
...
>>> p = PersonClass4()
>>> t.render(Context({"person": p}))
"My name is ."

```

Note that `django.core.exceptions.ObjectDoesNotExist`, which is the base class for all Django database API `DoesNotExist` exceptions, has `silent_variable_failure = True`. So if you're using Django templates with Django model objects, any `DoesNotExist` exception will fail silently.

- A variable can only be called if it has no required arguments. Otherwise, the system will return the value of the engine's `string_if_invalid` option.
- There can be side effects when calling some variables, and it'd be either foolish or a security hole to allow the template system to access them.

A good example is the `delete()` method on each Django model object. The template system shouldn't be allowed to do something like this:

```
I will now delete this valuable data. {{ data.delete }}
```

To prevent this, set an `alters_data` attribute on the callable variable. The template system won't call a variable if it has `alters_data=True` set, and will instead replace the variable with `string_if_invalid`, unconditionally. The dynamically-generated `delete()` and `save()` methods on Django model objects get `alters_data=True` automatically. Example:

```

def sensitive_function(self):
    self.database_record.delete()

sensitive_function.alters_data = True

```

- Occasionally you may want to turn off this feature for other reasons, and tell the template system to leave a variable uncalled no matter what. To do so, set a `do_not_call_in_templates` attribute on the callable with the value `True`. The template system then will act as if your variable is not callable (allowing you to access attributes of the callable, for example).

How invalid variables are handled

Generally, if a variable doesn't exist, the template system inserts the value of the engine's `string_if_invalid` configuration option, which is set to `''` (the empty string) by default.

Filters that are applied to an invalid variable will only be applied if `string_if_invalid` is set to `''` (the empty string). If `string_if_invalid` is set to any other value, variable filters will be ignored.

This behavior is slightly different for the `if`, `for` and `regroup` template tags. If an invalid variable is provided to one of these template tags, the variable will be interpreted as `None`. Filters are always applied to invalid variables within these template tags.

If `string_if_invalid` contains a `'%s'`, the format marker will be replaced with the name of the invalid variable.

For debug purposes only!

While `string_if_invalid` can be a useful debugging tool, it is a bad idea to turn it on as a 'development default'.

Many templates, including some of Django's, rely upon the silence of the template system when a nonexistent variable is encountered. If you assign a value other than `''` to `string_if_invalid`, you will experience rendering problems with these templates and sites.

Generally, `string_if_invalid` should only be enabled in order to debug a specific template problem, then cleared once debugging is complete.

Built-in variables

Every context contains `True`, `False` and `None`. As you would expect, these variables resolve to the corresponding Python objects.

Limitations with string literals

Django's template language has no way to escape the characters used for its own syntax. For example, the `templatetag` tag is required if you need to output character sequences like `{%` and `%}`.

A similar issue exists if you want to include these sequences in template filter or tag arguments. For example, when parsing a block tag, Django's template parser looks for the first occurrence of `%}` after a `{%`. This prevents the use of `"%}"` as a string literal. For example, a `TemplateSyntaxError` will be raised for the following expressions:

```
{% include "template.html" tvar="Some string literal with %}" %}

{% with tvar="Some string literal with %}" in it." %}{% endwith %}
```

The same issue can be triggered by using a reserved sequence in filter arguments:

```
{{ some.variable|default:"}" }} }
```

If you need to use strings with these sequences, store them in template variables or use a custom template tag or filter to workaround the limitation.

Playing with Context objects

Most of the time, you'll instantiate `Context` objects by passing in a fully-populated dictionary to `Context()`. But you can add and delete items from a `Context` object once it's been instantiated, too, using standard dictionary syntax:

```
>>> from django.template import Context
>>> c = Context({"foo": "bar"})
>>> c["foo"]
'bar'
>>> del c["foo"]
>>> c["foo"]
Traceback (most recent call last):
...
KeyError: 'foo'
>>> c["newvariable"] = "hello"
>>> c["newvariable"]
'hello'
```

`Context.get(key, otherwise=None)`

Returns the value for `key` if `key` is in the context, else returns `otherwise`.

`Context.setdefault(key, default=None)`

If `key` is in the context, returns its value. Otherwise inserts `key` with a value of `default` and returns `default`.

`Context.pop()`

`Context.push()`

exception `ContextPopException`

A `Context` object is a stack. That is, you can `push()` and `pop()` it. If you `pop()` too much, it'll raise `django.template.ContextPopException`:

```
>>> c = Context()
>>> c["foo"] = "first level"
>>> c.push()
{}
>>> c["foo"] = "second level"
>>> c["foo"]
'second level'
>>> c.pop()
{'foo': 'second level'}
>>> c["foo"]
'first level'
>>> c["foo"] = "overwritten"
>>> c["foo"]
'overwritten'
>>> c.pop()
Traceback (most recent call last):
...
ContextPopException
```

You can also use `push()` as a context manager to ensure a matching `pop()` is called.

```
>>> c = Context()
>>> c['foo'] = 'first level'
>>> with c.push():
...     c['foo'] = 'second level'
...     c['foo']
'second level'
>>> c['foo']
'first level'
```

All arguments passed to `push()` will be passed to the `dict` constructor used to build the new context level.

```
>>> c = Context()
>>> c['foo'] = 'first level'
>>> with c.push(foo='second level'):
...     c['foo']
'second level'
>>> c['foo']
'first level'
```

`Context.update(other_dict)`

In addition to `push()` and `pop()`, the `Context` object also defines an `update()` method. This works like `push()` but takes a dictionary as an argument and pushes that dictionary onto the stack instead of an empty one.

```
>>> c = Context()
>>> c['foo'] = 'first level'
>>> c.update({'foo': 'updated'})
{'foo': 'updated'}
>>> c['foo']
'updated'
>>> c.pop()
{'foo': 'updated'}
>>> c['foo']
'first level'
```

Like `push()`, you can use `update()` as a context manager to ensure a matching `pop()` is called.

```
>>> c = Context()
>>> c['foo'] = 'first level'
>>> with c.update({'foo': 'second level'}):
...     c['foo']
'second level'
>>> c['foo']
'first level'
```

Using a `Context` as a stack comes in handy in [some custom template tags](#).

`Context.flatten()`

Using `flatten()` method you can get whole `Context` stack as one dictionary including builtin variables.

```
>>> c = Context()
>>> c['foo'] = 'first level'
>>> c.update({'bar': 'second level'})
{'bar': 'second level'}
>>> c.flatten()
{'True': True, 'None': None, 'foo': 'first level', 'False': False, 'bar': 'second level'}
```

A `flatten()` method is also internally used to make `Context` objects comparable.

```
>>> c1 = Context()
>>> c1['foo'] = 'first level'
>>> c1['bar'] = 'second level'
>>> c2 = Context()
>>> c2.update({'bar': 'second level', 'foo': 'first level'})
{'foo': 'first level', 'bar': 'second level'}
>>> c1 == c2
True
```

Result from `flatten()` can be useful in unit tests to compare `Context` against dict:

```
class ContextTest(unittest.TestCase):
    def test_against_dictionary(self):
        c1 = Context()
        c1["update"] = "value"
        self.assertEqual(
            c1.flatten(),
            {
                "True": True,
                "None": None,
                "False": False,
                "update": "value",
            },
        )
```

Using RequestContext

```
class RequestContext(request, dict_=None, processors=None)
```

Django comes with a special `Context` class, `django.template.RequestContext`, that acts slightly differently from the normal `django.template.Context`. The first difference is that it takes an *HttpRequest* as its first argument. For example:

```
c = RequestContext(
    request,
    {
        "foo": "bar",
    },
)
```

The second difference is that it automatically populates the context with a few variables, according to the engine's `context_processors` configuration option.

The `context_processors` option is a list of callables –called context processors–that take a request object as their argument and return a dictionary of items to be merged into the context. In the default generated settings file, the default template engine contains the following context processors:

```
[
    "django.template.context_processors.debug",
    "django.template.context_processors.request",
    "django.contrib.auth.context_processors.auth",
    "django.contrib.messages.context_processors.messages",
]
```

In addition to these, *RequestContext* always enables `'django.template.context_processors.csrf'`. This is a security related context processor required by the admin and other contrib apps, and, in case of accidental misconfiguration, it is deliberately hardcoded in and cannot be turned off in the `context_processors` option.

Each processor is applied in order. That means, if one processor adds a variable to the context and a second processor adds a variable with the same name, the second will override the first. The default processors are explained below.

When context processors are applied

Context processors are applied on top of context data. This means that a context processor may overwrite variables you’ve supplied to your *Context* or *RequestContext*, so take care to avoid variable names that overlap with those supplied by your context processors.

If you want context data to take priority over context processors, use the following pattern:

```
from django.template import RequestContext

request_context = RequestContext(request)
request_context.push({"my_name": "Adrian"})
```

Django does this to allow context data to override context processors in APIs such as *render()* and *TemplateResponse*.

Also, you can give *RequestContext* a list of additional processors, using the optional, third positional argument, `processors`. In this example, the *RequestContext* instance gets an `ip_address` variable:

```
from django.http import HttpResponse
from django.template import RequestContext, Template

def ip_address_processor(request):
    return {"ip_address": request.META["REMOTE_ADDR"]}
```

(continues on next page)

(continued from previous page)

```
def client_ip_view(request):
    template = Template("{% title %}: {% ip_address %}")
    context = RequestContext(
        request,
        {
            "title": "Your IP Address",
        },
        [ip_address_processor],
    )
    return HttpResponse(template.render(context))
```

Built-in template context processors

Here's what each of the built-in processors does:

`django.contrib.auth.context_processors.auth`

`auth(request)`

If this processor is enabled, every `RequestContext` will contain these variables:

- `user` –An `auth.User` instance representing the currently logged-in user (or an `AnonymousUser` instance, if the client isn't logged in).
- `perms` –An instance of `django.contrib.auth.context_processors.PermWrapper`, representing the permissions that the currently logged-in user has.

`django.template.context_processors.debug`

`debug(request)`

If this processor is enabled, every `RequestContext` will contain these two variables –but only if your `DEBUG` setting is set to `True` and the request's IP address (`request.META['REMOTE_ADDR']`) is in the `INTERNAL_IPS` setting:

- `debug` –`True`. You can use this in templates to test whether you're in `DEBUG` mode.
- `sql_queries` –A list of `{'sql': ..., 'time': ...}` dictionaries, representing every SQL query that has happened so far during the request and how long it took. The list is in order by database alias and then by query. It's lazily generated on access.

`django.template.context_processors.i18n`

`i18n(request)`

If this processor is enabled, every `RequestContext` will contain these variables:

- `LANGUAGES` –The value of the `LANGUAGES` setting.
- `LANGUAGE_BIDI` –True if the current language is a right-to-left language, e.g. Hebrew, Arabic. False if it's a left-to-right language, e.g. English, French, German.
- `LANGUAGE_CODE` –`request.LANGUAGE_CODE`, if it exists. Otherwise, the value of the `LANGUAGE_CODE` setting.

See `i18n` [template tags](#) for template tags that generate the same values.

`django.template.context_processors.media`

If this processor is enabled, every `RequestContext` will contain a variable `MEDIA_URL`, providing the value of the `MEDIA_URL` setting.

`django.template.context_processors.static`

`static(request)`

If this processor is enabled, every `RequestContext` will contain a variable `STATIC_URL`, providing the value of the `STATIC_URL` setting.

`django.template.context_processors.csrf`

This processor adds a token that is needed by the `csrf_token` template tag for protection against Cross Site Request Forgeries.

`django.template.context_processors.request`

If this processor is enabled, every `RequestContext` will contain a variable `request`, which is the current *`HttpRequest`*.

```
django.template.context_processors.tz
```

```
tz(request)
```

If this processor is enabled, every `RequestContext` will contain a variable `TIME_ZONE`, providing the name of the currently active time zone.

```
django.contrib.messages.context_processors.messages
```

If this processor is enabled, every `RequestContext` will contain these two variables:

- `messages` –A list of messages (as strings) that have been set via the [messages framework](#).
- `DEFAULT_MESSAGE_LEVELS` –A mapping of the message level names to [their numeric value](#).

Writing your own context processors

A context processor has a simple interface: It’s a Python function that takes one argument, an [*HttpRequest*](#) object, and returns a dictionary that gets added to the template context.

For example, to add the [*DEFAULT_FROM_EMAIL*](#) setting to every context:

```
from django.conf import settings

def from_email(request):
    return {
        "DEFAULT_FROM_EMAIL": settings.DEFAULT_FROM_EMAIL,
    }
```

Custom context processors can live anywhere in your code base. All Django cares about is that your custom context processors are pointed to by the `'context_processors'` option in your [*TEMPLATES*](#) setting —or the `context_processors` argument of [*Engine*](#) if you’re using it directly.

Loading templates

Generally, you’ll store templates in files on your filesystem rather than using the low-level [*Template*](#) API yourself. Save templates in a directory specified as a template directory.

Django searches for template directories in a number of places, depending on your template loading settings (see “Loader types” below), but the most basic way of specifying template directories is by using the [*DIRS*](#) option.

The `DIRS` option

Tell Django what your template directories are by using the `DIRS` option in the `TEMPLATES` setting in your settings file—or the `dirs` argument of `Engine`. This should be set to a list of strings that contain full paths to your template directories:

```
TEMPLATES = [
    {
        "BACKEND": "django.template.backends.django.DjangoTemplates",
        "DIRS": [
            "/home/html/templates/lawrence.com",
            "/home/html/templates/default",
        ],
    },
]
```

Your templates can go anywhere you want, as long as the directories and templates are readable by the web server. They can have any extension you want, such as `.html` or `.txt`, or they can have no extension at all.

Note that these paths should use Unix-style forward slashes, even on Windows.

Loader types

By default, Django uses a filesystem-based template loader, but Django comes with a few other template loaders, which know how to load templates from other sources.

Some of these other loaders are disabled by default, but you can activate them by adding a `'loaders'` option to your `DjangoTemplates` backend in the `TEMPLATES` setting or passing a `loaders` argument to `Engine`. `loaders` should be a list of strings or tuples, where each represents a template loader class. Here are the template loaders that come with Django:

```
django.template.loaders.filesystem.Loader
```

```
class filesystem.Loader
```

Loads templates from the filesystem, according to `DIRS`.

This loader is enabled by default. However it won't find any templates until you set `DIRS` to a non-empty list:

```
TEMPLATES = [
    {
        "BACKEND": "django.template.backends.django.DjangoTemplates",
        "DIRS": [BASE_DIR / "templates"],
    },
]
```

You can also override 'DIRS' and specify specific directories for a particular filesystem loader:

```
TEMPLATES = [
    {
        "BACKEND": "django.template.backends.django.DjangoTemplates",
        "OPTIONS": {
            "loaders": [
                (
                    "django.template.loaders.filesystem.Loader",
                    [BASE_DIR / "templates"],
                ),
            ],
        },
    },
]
```

`django.template.loaders.app_directories.Loader`

`class app_directories.Loader`

Loads templates from Django apps on the filesystem. For each app in [`INSTALLED\_APPS`](#), the loader looks for a `templates` subdirectory. If the directory exists, Django looks for templates in there.

This means you can store templates with your individual apps. This also helps to distribute Django apps with default templates.

For example, for this setting:

```
INSTALLED_APPS = ["myproject.polls", "myproject.music"]
```

...then `get_template('foo.html')` will look for `foo.html` in these directories, in this order:

- `/path/to/myproject/polls/templates/`
- `/path/to/myproject/music/templates/`

... and will use the one it finds first.

The order of [`INSTALLED\_APPS`](#) is significant! For example, if you want to customize the Django admin, you might choose to override the standard `admin/base_site.html` template, from `django.contrib.admin`, with your own `admin/base_site.html` in `myproject.polls`. You must then make sure that your `myproject.polls` comes before `django.contrib.admin` in [`INSTALLED\_APPS`](#), otherwise `django.contrib.admin`'s will be loaded first and yours will be ignored.

Note that the loader performs an optimization when it first runs: it caches a list of which [`INSTALLED\_APPS`](#) packages have a `templates` subdirectory.

You can enable this loader by setting [`APP\_DIRS`](#) to `True`:

```

TEMPLATES = [
    {
        "BACKEND": "django.template.backends.django.DjangoTemplates",
        "APP_DIRS": True,
    }
]

```

`django.template.loaders.cached.Loader`

`class cached.Loader`

While the Django template system is quite fast, if it needs to read and compile your templates every time they're rendered, the overhead from that can add up.

You configure the cached template loader with a list of other loaders that it should wrap. The wrapped loaders are used to locate unknown templates when they're first encountered. The cached loader then stores the compiled `Template` in memory. The cached `Template` instance is returned for subsequent requests to load the same template.

This loader is automatically enabled if `OPTIONS['loaders']` isn't specified.

You can manually specify template caching with some custom template loaders using settings like this:

```

TEMPLATES = [
    {
        "BACKEND": "django.template.backends.django.DjangoTemplates",
        "DIRS": [BASE_DIR / "templates"],
        "OPTIONS": {
            "loaders": [
                (
                    "django.template.loaders.cached.Loader",
                    [
                        "django.template.loaders.filesystem.Loader",
                        "django.template.loaders.app_directories.Loader",
                        "path.to.custom.Loader",
                    ],
                ),
            ],
        },
    }
]

```

Note: All of the built-in Django template tags are safe to use with the cached loader, but if you're using custom template tags that come from third party packages, or that you wrote yourself, you should ensure that the Node implementation for each tag is thread-safe. For more information, see

[template tag thread safety considerations](#).

The cached template loader was enabled whenever `OPTIONS['loaders']` is not specified. Previously it was only enabled when `DEBUG` was `False`.

`django.template.loaders.locmem.Loader`

class `locmem.Loader`

Loads templates from a Python dictionary. This is useful for testing.

This loader takes a dictionary of templates as its first argument:

```
TEMPLATES = [
    {
        "BACKEND": "django.template.backends.django.DjangoTemplates",
        "OPTIONS": {
            "loaders": [
                (
                    "django.template.loaders.locmem.Loader",
                    {
                        "index.html": "content here",
                    },
                ),
            ],
        },
    },
]
```

This loader is disabled by default.

Django uses the template loaders in order according to the `'loaders'` option. It uses each loader until a loader finds a match.

Custom loaders

It's possible to load templates from additional sources using custom template loaders. Custom Loader classes should inherit from `django.template.loaders.base.Loader` and define the `get_contents()` and `get_template_sources()` methods.

Loader methods

`class Loader`

Loads templates from a given source, such as the filesystem or a database.

`get_template_sources(template_name)`

A method that takes a `template_name` and yields *Origin* instances for each possible source.

For example, the filesystem loader may receive `'index.html'` as a `template_name` argument. This method would yield origins for the full path of `index.html` as it appears in each template directory the loader looks at.

The method doesn't need to verify that the template exists at a given path, but it should ensure the path is valid. For instance, the filesystem loader makes sure the path lies under a valid template directory.

`get_contents(origin)`

Returns the contents for a template given a *Origin* instance.

This is where a filesystem loader would read contents from the filesystem, or a database loader would read from the database. If a matching template doesn't exist, this should raise a *TemplateDoesNotExist* error.

`get_template(template_name, skip=None)`

Returns a `Template` object for a given `template_name` by looping through results from `get_template_sources()` and calling `get_contents()`. This returns the first matching template. If no template is found, *TemplateDoesNotExist* is raised.

The optional `skip` argument is a list of origins to ignore when extending templates. This allows templates to extend other templates of the same name. It is also used to avoid recursion errors.

In general, it is enough to define `get_template_sources()` and `get_contents()` for custom template loaders. `get_template()` will usually not need to be overridden.

Building your own

For examples, read the [source code](#) for Django's built-in loaders.

Template origin

Templates have an `origin` containing attributes depending on the source they are loaded from.

```
class Origin(name, template_name=None, loader=None)
```

`name`

The path to the template as returned by the template loader. For loaders that read from the file system, this is the full path to the template.

If the template is instantiated directly rather than through a template loader, this is a string value of `<unknown_source>`.

`template_name`

The relative path to the template as passed into the template loader.

If the template is instantiated directly rather than through a template loader, this is `None`.

`loader`

The template loader instance that constructed this `Origin`.

If the template is instantiated directly rather than through a template loader, this is `None`.

`django.template.loaders.cached.Loader` requires all of its wrapped loaders to set this attribute, typically by instantiating the `Origin` with `loader=self`.

6.23 TemplateResponse and SimpleTemplateResponse

Standard `HttpResponse` objects are static structures. They are provided with a block of pre-rendered content at time of construction, and while that content can be modified, it isn't in a form that makes it easy to perform modifications.

However, it can sometimes be beneficial to allow decorators or middleware to modify a response after it has been constructed by the view. For example, you may want to change the template that is used, or put additional data into the context.

`TemplateResponse` provides a way to do just that. Unlike basic `HttpResponse` objects, `TemplateResponse` objects retain the details of the template and context that was provided by the view to compute the response. The final output of the response is not computed until it is needed, later in the response process.

6.23.1 SimpleTemplateResponse objects

```
class SimpleTemplateResponse
```

Attributes

`SimpleTemplateResponse.template_name`

The name of the template to be rendered. Accepts a backend-dependent template object (such as those returned by `get_template()`), the name of a template, or a list of template names.

Example: `['foo.html', 'path/to/bar.html']`

`SimpleTemplateResponse.context_data`

The context data to be used when rendering the template. It must be a `dict`.

Example: `{'foo': 123}`

`SimpleTemplateResponse.rendered_content`

The current rendered value of the response content, using the current template and context data.

`SimpleTemplateResponse.is_rendered`

A boolean indicating whether the response content has been rendered.

Methods

`SimpleTemplateResponse.__init__(template, context=None, content_type=None, status=None, charset=None, using=None, headers=None)`

Instantiates a *SimpleTemplateResponse* object with the given template, context, content type, HTTP status, and charset.

template

A backend-dependent template object (such as those returned by `get_template()`), the name of a template, or a list of template names.

context

A `dict` of values to add to the template context. By default, this is an empty dictionary.

content_type

The value included in the HTTP `Content-Type` header, including the MIME type specification and the character set encoding. If `content_type` is specified, then its value is used. Otherwise, `'text/html'` is used.

status

The HTTP status code for the response.

charset

The charset in which the response will be encoded. If not given it will be extracted from `content_type`, and if that is unsuccessful, the `DEFAULT_CHARSET` setting will be used.

using

The *NAME* of a template engine to use for loading the template.

headers

A `dict` of HTTP headers to add to the response.

SimpleTemplateResponse.resolve_context(context)

Preprocesses context data that will be used for rendering a template. Accepts a `dict` of context data. By default, returns the same `dict`.

Override this method in order to customize the context.

SimpleTemplateResponse.resolve_template(template)

Resolves the template instance to use for rendering. Accepts a backend-dependent template object (such as those returned by `get_template()`), the name of a template, or a list of template names.

Returns the backend-dependent template object instance to be rendered.

Override this method in order to customize template loading.

SimpleTemplateResponse.add_post_render_callback()

Add a callback that will be invoked after rendering has taken place. This hook can be used to defer certain processing operations (such as caching) until after rendering has occurred.

If the *SimpleTemplateResponse* has already been rendered, the callback will be invoked immediately.

When called, callbacks will be passed a single argument –the rendered *SimpleTemplateResponse* instance.

If the callback returns a value that is not `None`, this will be used as the response instead of the original response object (and will be passed to the next post rendering callback etc.)

SimpleTemplateResponse.render()

Sets `response.content` to the result obtained by *SimpleTemplateResponse.rendered_content*, runs all post-rendering callbacks, and returns the resulting response object.

`render()` will only have an effect the first time it is called. On subsequent calls, it will return the result obtained from the first call.

6.23.2 TemplateResponse objects

class TemplateResponse

TemplateResponse is a subclass of *SimpleTemplateResponse* that knows about the current *HttpRequest*.

Methods

TemplateResponse.__init__(request, template, context=None, content_type=None, status=None, charset=None, using=None, headers=None)

Instantiates a *TemplateResponse* object with the given request, template, context, content type, HTTP status, and charset.

request

An *HttpRequest* instance.

template

A backend-dependent template object (such as those returned by *get_template()*), the name of a template, or a list of template names.

context

A *dict* of values to add to the template context. By default, this is an empty dictionary.

content_type

The value included in the HTTP Content-Type header, including the MIME type specification and the character set encoding. If *content_type* is specified, then its value is used. Otherwise, 'text/html' is used.

status

The HTTP status code for the response.

charset

The charset in which the response will be encoded. If not given it will be extracted from *content_type*, and if that is unsuccessful, the *DEFAULT_CHARSET* setting will be used.

using

The *NAME* of a template engine to use for loading the template.

headers

A *dict* of HTTP headers to add to the response.

6.23.3 The rendering process

Before a `TemplateResponse` instance can be returned to the client, it must be rendered. The rendering process takes the intermediate representation of template and context, and turns it into the final byte stream that can be served to the client.

There are three circumstances under which a `TemplateResponse` will be rendered:

- When the `TemplateResponse` instance is explicitly rendered, using the `SimpleTemplateResponse.render()` method.
- When the content of the response is explicitly set by assigning `response.content`.
- After passing through template response middleware, but before passing through response middleware.

A `TemplateResponse` can only be rendered once. The first call to `SimpleTemplateResponse.render()` sets the content of the response; subsequent rendering calls do not change the response content.

However, when `response.content` is explicitly assigned, the change is always applied. If you want to force the content to be re-rendered, you can reevaluate the rendered content, and assign the content of the response manually:

```
# Set up a rendered TemplateResponse
>>> from django.template.response import TemplateResponse
>>> t = TemplateResponse(request, "original.html", {})
>>> t.render()
>>> print(t.content)
Original content

# Re-rendering doesn't change content
>>> t.template_name = "new.html"
>>> t.render()
>>> print(t.content)
Original content

# Assigning content does change, no render() call required
>>> t.content = t.rendered_content
>>> print(t.content)
New content
```

Post-render callbacks

Some operations –such as caching –cannot be performed on an unrendered template. They must be performed on a fully complete and rendered response.

If you’re using middleware, you can do that. Middleware provides multiple opportunities to process a response on exit from a view. If you put behavior in the response middleware, it’s guaranteed to execute after template rendering has taken place.

However, if you’re using a decorator, the same opportunities do not exist. Any behavior defined in a decorator is handled immediately.

To compensate for this (and any other analogous use cases), *TemplateResponse* allows you to register callbacks that will be invoked when rendering has completed. Using this callback, you can defer critical processing until a point where you can guarantee that rendered content will be available.

To define a post-render callback, define a function that takes a single argument –response –and register that function with the template response:

```
from django.template.response import TemplateResponse

def my_render_callback(response):
    # Do content-sensitive processing
    do_post_processing()

def my_view(request):
    # Create a response
    response = TemplateResponse(request, "mytemplate.html", {})
    # Register the callback
    response.add_post_render_callback(my_render_callback)
    # Return the response
    return response
```

`my_render_callback()` will be invoked after the `mytemplate.html` has been rendered, and will be provided the fully rendered *TemplateResponse* instance as an argument.

If the template has already been rendered, the callback will be invoked immediately.

6.23.4 Using `TemplateResponse` and `SimpleTemplateResponse`

A `TemplateResponse` object can be used anywhere that a normal `django.http.HttpResponse` can be used. It can also be used as an alternative to calling `render()`.

For example, the following view returns a `TemplateResponse` with a template and a context containing a queryset:

```
from django.template.response import TemplateResponse

def blog_index(request):
    return TemplateResponse(
        request, "entry_list.html", {"entries": Entry.objects.all()}
    )
```

6.24 Unicode data

Django supports Unicode data everywhere.

This document tells you what you need to know if you’re writing applications that use data or templates that are encoded in something other than ASCII.

6.24.1 Creating the database

Make sure your database is configured to be able to store arbitrary string data. Normally, this means giving it an encoding of UTF-8 or UTF-16. If you use a more restrictive encoding –for example, latin1 (iso8859-1) – you won’t be able to store certain characters in the database, and information will be lost.

- MySQL users, refer to the [MySQL manual](#) for details on how to set or alter the database character set encoding.
- PostgreSQL users, refer to the [PostgreSQL manual](#) for details on creating databases with the correct encoding.
- Oracle users, refer to the [Oracle manual](#) for details on how to set (section 2) or alter (section 11) the database character set encoding.
- SQLite users, there is nothing you need to do. SQLite always uses UTF-8 for internal encoding.

All of Django’s database backends automatically convert strings into the appropriate encoding for talking to the database. They also automatically convert strings retrieved from the database into strings. You don’t even need to tell Django what encoding your database uses: that is handled transparently.

For more, see the section “The database API” below.

6.24.2 General string handling

Whenever you use strings with Django –e.g., in database lookups, template rendering or anywhere else –you have two choices for encoding those strings. You can use normal strings or bytestrings (starting with a `'b'`).

Warning: A bytestring does not carry any information with it about its encoding. For that reason, we have to make an assumption, and Django assumes that all bytestrings are in UTF-8.

If you pass a string to Django that has been encoded in some other format, things will go wrong in interesting ways. Usually, Django will raise a `UnicodeDecodeError` at some point.

If your code only uses ASCII data, it's safe to use your normal strings, passing them around at will, because ASCII is a subset of UTF-8.

Don't be fooled into thinking that if your `DEFAULT_CHARSET` setting is set to something other than `'utf-8'` you can use that other encoding in your bytestrings! `DEFAULT_CHARSET` only applies to the strings generated as the result of template rendering (and email). Django will always assume UTF-8 encoding for internal bytestrings. The reason for this is that the `DEFAULT_CHARSET` setting is not actually under your control (if you are the application developer). It's under the control of the person installing and using your application –and if that person chooses a different setting, your code must still continue to work. Ergo, it cannot rely on that setting.

In most cases when Django is dealing with strings, it will convert them to strings before doing anything else. So, as a general rule, if you pass in a bytestring, be prepared to receive a string back in the result.

Translated strings

Aside from strings and bytestrings, there's a third type of string-like object you may encounter when using Django. The framework's internationalization features introduce the concept of a “lazy translation” –a string that has been marked as translated but whose actual translation result isn't determined until the object is used in a string. This feature is useful in cases where the translation locale is unknown until the string is used, even though the string might have originally been created when the code was first imported.

Normally, you won't have to worry about lazy translations. Just be aware that if you examine an object and it claims to be a `django.utils.functional.__proxy__` object, it is a lazy translation. Calling `str()` with the lazy translation as the argument will generate a string in the current locale.

For more details about lazy translation objects, refer to the [internationalization](#) documentation.

Useful utility functions

Because some string operations come up again and again, Django ships with a few useful functions that should make working with string and bytestring objects a bit easier.

Conversion functions

The `django.utils.encoding` module contains a few functions that are handy for converting back and forth between strings and bytestrings.

- `smart_str(s, encoding='utf-8', strings_only=False, errors='strict')` converts its input to a string. The `encoding` parameter specifies the input encoding. (For example, Django uses this internally when processing form input data, which might not be UTF-8 encoded.) The `strings_only` parameter, if set to `True`, will result in Python numbers, booleans and `None` not being converted to a string (they keep their original types). The `errors` parameter takes any of the values that are accepted by Python's `str()` function for its error handling.
- `force_str(s, encoding='utf-8', strings_only=False, errors='strict')` is identical to `smart_str()` in almost all cases. The difference is when the first argument is a [lazy translation](#) instance. While `smart_str()` preserves lazy translations, `force_str()` forces those objects to a string (causing the translation to occur). Normally, you'll want to use `smart_str()`. However, `force_str()` is useful in template tags and filters that absolutely must have a string to work with, not just something that can be converted to a string.
- `smart_bytes(s, encoding='utf-8', strings_only=False, errors='strict')` is essentially the opposite of `smart_str()`. It forces the first argument to a bytestring. The `strings_only` parameter has the same behavior as for `smart_str()` and `force_str()`. This is slightly different semantics from Python's builtin `str()` function, but the difference is needed in a few places within Django's internals.

Normally, you'll only need to use `force_str()`. Call it as early as possible on any input data that might be either a string or a bytestring, and from then on, you can treat the result as always being a string.

URI and IRI handling

Web frameworks have to deal with URLs (which are a type of IRI). One requirement of URLs is that they are encoded using only ASCII characters. However, in an international environment, you might need to construct a URL from an [IRI](#)—very loosely speaking, a [URI](#) that can contain Unicode characters. Use these functions for quoting and converting an IRI to a URI:

- The `django.utils.encoding.iri_to_uri()` function, which implements the conversion from IRI to URI as required by [RFC 3987#section-3.1](#).
- The `urllib.parse.quote()` and `urllib.parse.quote_plus()` functions from Python's standard library.

These two groups of functions have slightly different purposes, and it's important to keep them straight. Normally, you would use `quote()` on the individual portions of the IRI or URI path so that any reserved characters such as `'&'` or `'%'` are correctly encoded. Then, you apply `iri_to_uri()` to the full IRI and it converts any non-ASCII characters to the correct encoded values.

Note: Technically, it isn't correct to say that `iri_to_uri()` implements the full algorithm in the IRI specification. It doesn't (yet) perform the international domain name encoding portion of the algorithm.

The `iri_to_uri()` function will not change ASCII characters that are otherwise permitted in a URL. So, for example, the character `'%'` is not further encoded when passed to `iri_to_uri()`. This means you can pass a full URL to this function and it will not mess up the query string or anything like that.

An example might clarify things here:

```
>>> from urllib.parse import quote
>>> from django.utils.encoding import iri_to_uri
>>> quote("Paris & Orléans")
'Paris%20%26%20Orl%C3%A9ans'
>>> iri_to_uri("/favorites/François/%s" % quote("Paris & Orléans"))
'/favorites/Fran%C3%A7ois/Paris%20%26%20Orl%C3%A9ans'
```

If you look carefully, you can see that the portion that was generated by `quote()` in the second example was not double-quoted when passed to `iri_to_uri()`. This is a very important and useful feature. It means that you can construct your IRI without worrying about whether it contains non-ASCII characters and then, right at the end, call `iri_to_uri()` on the result.

Similarly, Django provides `django.utils.encoding.uri_to_iri()` which implements the conversion from URI to IRI as per RFC 3987#section-3.2.

An example to demonstrate:

```
>>> from django.utils.encoding import uri_to_iri
>>> uri_to_iri("/%E2%99%A5%E2%99%A5/?utf8=%E2%9C%93")
'/♡/?utf8=✓'
>>> uri_to_iri("%A9hello%3Fworld")
'%A9hello%3Fworld'
```

In the first example, the UTF-8 characters are unquoted. In the second, the percent-encodings remain unchanged because they lie outside the valid UTF-8 range or represent a reserved character.

Both `iri_to_uri()` and `uri_to_iri()` functions are idempotent, which means the following is always true:

```
iri_to_uri(iri_to_uri(some_string)) == iri_to_uri(some_string)
uri_to_iri(uri_to_iri(some_string)) == uri_to_iri(some_string)
```

So you can safely call it multiple times on the same URI/IRI without risking double-quoting problems.

6.24.3 Models

Because all strings are returned from the database as `str` objects, model fields that are character based (`CharField`, `TextField`, `URLField`, etc.) will contain Unicode values when Django retrieves data from the database. This is always the case, even if the data could fit into an ASCII bytestring.

You can pass in bytestrings when creating a model or populating a field, and Django will convert it to strings when it needs to.

Taking care in `get_absolute_url()`

URLs can only contain ASCII characters. If you’re constructing a URL from pieces of data that might be non-ASCII, be careful to encode the results in a way that is suitable for a URL. The `reverse()` function handles this for you automatically.

If you’re constructing a URL manually (i.e., not using the `reverse()` function), you’ll need to take care of the encoding yourself. In this case, use the `iri_to_uri()` and `quote()` functions that were documented above. For example:

```
from urllib.parse import quote
from django.utils.encoding import iri_to_uri

def get_absolute_url(self):
    url = "/person/%s/?x=0&y=0" % quote(self.location)
    return iri_to_uri(url)
```

This function returns a correctly encoded URL even if `self.location` is something like “Jack visited Paris & Orléans”. (In fact, the `iri_to_uri()` call isn’t strictly necessary in the above example, because all the non-ASCII characters would have been removed in quoting in the first line.)

6.24.4 Templates

Use strings when creating templates manually:

```
from django.template import Template

t2 = Template("This is a string template.")
```

But the common case is to read templates from the filesystem. If your template files are not stored with a UTF-8 encoding, adjust the `TEMPLATES` setting. The built-in *django* backend provides the `'file_charset'` option to change the encoding used to read files from disk.

The `DEFAULT_CHARSET` setting controls the encoding of rendered templates. This is set to UTF-8 by default.

Template tags and filters

A couple of tips to remember when writing your own template tags and filters:

- Always return strings from a template tag’s `render()` method and from template filters.
- Use `force_str()` in preference to `smart_str()` in these places. Tag rendering and filter calls occur as the template is being rendered, so there is no advantage to postponing the conversion of lazy translation objects into strings. It’s easier to work solely with strings at that point.

6.24.5 Files

If you intend to allow users to upload files, you must ensure that the environment used to run Django is configured to work with non-ASCII file names. If your environment isn’t configured correctly, you’ll encounter `UnicodeEncodeError` exceptions when saving files with file names or content that contains non-ASCII characters.

Filesystem support for UTF-8 file names varies and might depend on the environment. Check your current configuration in an interactive Python shell by running:

```
import sys

sys.getfilesystemencoding()
```

This should output “UTF-8”.

The `LANG` environment variable is responsible for setting the expected encoding on Unix platforms. Consult the documentation for your operating system and application server for the appropriate syntax and location to set this variable. See the [How to use Django with Apache and mod_wsgi](#) for examples.

In your development environment, you might need to add a setting to your `~.bashrc` analogous to:

```
export LANG="en_US.UTF-8"
```

6.24.6 Form submission

HTML form submission is a tricky area. There’s no guarantee that the submission will include encoding information, which means the framework might have to guess at the encoding of submitted data.

Django adopts a “lazy” approach to decoding form data. The data in an `HttpRequest` object is only decoded when you access it. In fact, most of the data is not decoded at all. Only the `HttpRequest.GET` and `HttpRequest.POST` data structures have any decoding applied to them. Those two fields will return their members as Unicode data. All other attributes and methods of `HttpRequest` return data exactly as it was submitted by the client.

By default, the `DEFAULT_CHARSET` setting is used as the assumed encoding for form data. If you need to change this for a particular form, you can set the `encoding` attribute on an `HttpRequest` instance. For example:

```
def some_view(request):
    # We know that the data must be encoded as KOI8-R (for some reason).
    request.encoding = "koi8-r"
    ...
```

You can even change the encoding after having accessed `request.GET` or `request.POST`, and all subsequent accesses will use the new encoding.

Most developers won't need to worry about changing form encoding, but this is a useful feature for applications that talk to legacy systems whose encoding you cannot control.

Django does not decode the data of file uploads, because that data is normally treated as collections of bytes, rather than strings. Any automatic decoding there would alter the meaning of the stream of bytes.

6.25 django.urls utility functions

6.25.1 reverse()

If you need to use something similar to the `url` template tag in your code, Django provides the following function:

reverse(viewname, urlconf=None, args=None, kwargs=None, current_app=None)

`viewname` can be a [URL pattern name](#) or the callable view object. For example, given the following `url`:

```
from news import views

path("archive/", views.archive, name="news-archive")
```

you can use any of the following to reverse the URL:

```
# using the named URL
reverse("news-archive")

# passing a callable object
# (This is discouraged because you can't reverse namespaced views this way.)
from news import views

reverse(views.archive)
```

If the URL accepts arguments, you may pass them in `args`. For example:

```
from django.urls import reverse

def myview(request):
    return HttpResponseRedirect(reverse("arch-summary", args=[1945]))
```

You can also pass `kwargs` instead of `args`. For example:

```
>>> reverse("admin:app_list", kwargs={"app_label": "auth"})
'/admin/auth/'
```

`args` and `kwargs` cannot be passed to `reverse()` at the same time.

If no match can be made, `reverse()` raises a *NoReverseMatch* exception.

The `reverse()` function can reverse a large variety of regular expression patterns for URLs, but not every possible one. The main restriction at the moment is that the pattern cannot contain alternative choices using the vertical bar (`|`) character. You can quite happily use such patterns for matching against incoming URLs and sending them off to views, but you cannot reverse such patterns.

The `current_app` argument allows you to provide a hint to the resolver indicating the application to which the currently executing view belongs. This `current_app` argument is used as a hint to resolve application namespaces into URLs on specific application instances, according to the [namespaced URL resolution strategy](#).

The `urlconf` argument is the `URLconf` module containing the URL patterns to use for reversing. By default, the root `URLconf` for the current thread is used.

Note: The string returned by `reverse()` is already *urlquoted*. For example:

```
>>> reverse("cities", args=["Orléans"])
'.../Orl%C3%A9ans/'
```

Applying further encoding (such as `urllib.parse.quote()`) to the output of `reverse()` may produce undesirable results.

6.25.2 `reverse_lazy()`

A lazily evaluated version of `reverse()`.

`reverse_lazy(viewname, urlconf=None, args=None, kwargs=None, current_app=None)`

It is useful for when you need to use a URL reversal before your project's `URLConf` is loaded. Some common cases where this function is necessary are:

- providing a reversed URL as the `url` attribute of a generic class-based view.
- providing a reversed URL to a decorator (such as the `login_url` argument for the `django.contrib.auth.decorators.permission_required()` decorator).
- providing a reversed URL as a default value for a parameter in a function's signature.

6.25.3 `resolve()`

The `resolve()` function can be used for resolving URL paths to the corresponding view functions. It has the following signature:

```
resolve(path, urlconf=None)
```

`path` is the URL path you want to resolve. As with `reverse()`, you don't need to worry about the `urlconf` parameter. The function returns a `ResolverMatch` object that allows you to access various metadata about the resolved URL.

If the URL does not resolve, the function raises a `Resolver404` exception (a subclass of `Http404`).

```
class ResolverMatch
```

```
    func
```

The view function that would be used to serve the URL

```
    args
```

The arguments that would be passed to the view function, as parsed from the URL.

```
    kwargs
```

All keyword arguments that would be passed to the view function, i.e. `captured_kwargs` and `extra_kwargs`.

```
    captured_kwargs
```

The captured keyword arguments that would be passed to the view function, as parsed from the URL.

```
    extra_kwargs
```

The additional keyword arguments that would be passed to the view function.

```
    url_name
```

The name of the URL pattern that matches the URL.

```
    route
```

The route of the matching URL pattern.

For example, if `path('users/<id>/', ...)` is the matching pattern, `route` will contain `'users/<id>/'`.

tried

The list of URL patterns tried before the URL either matched one or exhausted available patterns.

app_name

The application namespace for the URL pattern that matches the URL.

app_names

The list of individual namespace components in the full application namespace for the URL pattern that matches the URL. For example, if the `app_name` is `'foo:bar'`, then `app_names` will be `['foo', 'bar']`.

namespace

The instance namespace for the URL pattern that matches the URL.

namespaces

The list of individual namespace components in the full instance namespace for the URL pattern that matches the URL. i.e., if the namespace is `foo:bar`, then `namespaces` will be `['foo', 'bar']`.

view_name

The name of the view that matches the URL, including the namespace if there is one.

A `ResolverMatch` object can then be interrogated to provide information about the URL pattern that matches a URL:

```
# Resolve a URL
match = resolve("/some/path/")
# Print the URL pattern that matches the URL
print(match.url_name)
```

A `ResolverMatch` object can also be assigned to a triple:

```
func, args, kwargs = resolve("/some/path/")
```

One possible use of `resolve()` would be to test whether a view would raise a `Http404` error before redirecting to it:

```
from urllib.parse import urlparse
from django.urls import resolve
from django.http import Http404, HttpResponseRedirect

def myview(request):
    next = request.META.get("HTTP_REFERER", None) or "/"
    response = HttpResponseRedirect(next)

    # modify the request and response as required, e.g. change locale
```

(continues on next page)

(continued from previous page)

```
# and set corresponding locale cookie

view, args, kwargs = resolve(urlparse(next)[2])
kwargs["request"] = request
try:
    view(*args, **kwargs)
except Http404:
    return HttpResponseRedirect("/")
return response
```

6.25.4 `get_script_prefix()`

`get_script_prefix()`

Normally, you should always use `reverse()` to define URLs within your application. However, if your application constructs part of the URL hierarchy itself, you may occasionally need to generate URLs. In that case, you need to be able to find the base URL of the Django project within its web server (normally, `reverse()` takes care of this for you). In that case, you can call `get_script_prefix()`, which will return the script prefix portion of the URL for your Django project. If your Django project is at the root of its web server, this is always `"/"`.

Warning: This function cannot be used outside of the request-response cycle since it relies on values initialized during that cycle.

6.26 `django.urls` functions for use in `URLconfs`

6.26.1 `path()`

`path(route, view, kwargs=None, name=None)`

Returns an element for inclusion in `urlpatterns`. For example:

```
from django.urls import include, path

urlpatterns = [
    path("index/", views.index, name="main-view"),
    path("bio/<username>/", views.bio, name="bio"),
    path("articles/<slug:title>/", views.article, name="article-detail"),
    path("articles/<slug:title>/<int:section>/", views.section, name="article-section"),
```

(continues on next page)

(continued from previous page)

```

    path("blog/", include("blog.urls")),
    ...,
]

```

The `route` argument should be a string or `gettext_lazy()` (see [Translating URL patterns](#)) that contains a URL pattern. The string may contain angle brackets (like `<username>` above) to capture part of the URL and send it as a keyword argument to the view. The angle brackets may include a converter specification (like the `int` part of `<int:section>`) which limits the characters matched and may also change the type of the variable passed to the view. For example, `<int:section>` matches a string of decimal digits and converts the value to an `int`. See [How Django processes a request](#) for more details.

The `view` argument is a view function or the result of `as_view()` for class-based views. It can also be an `django.urls.include()`.

The `kwargs` argument allows you to pass additional arguments to the view function or method. See [Passing extra options to view functions](#) for an example.

See [Naming URL patterns](#) for why the `name` argument is useful.

6.26.2 re_path()

`re_path(route, view, kwargs=None, name=None)`

Returns an element for inclusion in `urlpatterns`. For example:

```

from django.urls import include, re_path

urlpatterns = [
    re_path(r"^index/$", views.index, name="index"),
    re_path(r"^bio/(?P<username>\w+)/$", views.bio, name="bio"),
    re_path(r"^blog/", include("blog.urls")),
    ...,
]

```

The `route` argument should be a string or `gettext_lazy()` (see [Translating URL patterns](#)) that contains a regular expression compatible with Python's `re` module. Strings typically use raw string syntax (`r' '`) so that they can contain sequences like `\d` without the need to escape the backslash with another backslash. When a match is made, captured groups from the regular expression are passed to the view –as named arguments if the groups are named, and as positional arguments otherwise. The values are passed as strings, without any type conversion.

When a `route` ends with `$` the whole requested URL, matching against `path_info`, must match the regular expression pattern (`re.fullmatch()` is used).

The `view`, `kwargs` and `name` arguments are the same as for `path()`.

In older versions, a full-match wasn't required for a route which ends with \$.

6.26.3 `include()`

`include(module, namespace=None)`

`include(pattern_list)`

`include((pattern_list, app_namespace), namespace=None)`

A function that takes a full Python import path to another URLconf module that should be “included” in this place. Optionally, the [application namespace](#) and [instance namespace](#) where the entries will be included into can also be specified.

Usually, the application namespace should be specified by the included module. If an application namespace is set, the `namespace` argument can be used to set a different instance namespace.

`include()` also accepts as an argument either an iterable that returns URL patterns or a 2-tuple containing such iterable plus the names of the application namespaces.

Parameters

- **module** –URLconf module (or module name)
- **namespace** (*str*) –Instance namespace for the URL entries being included
- **pattern_list** –Iterable of [path\(\)](#) and/or [re_path\(\)](#) instances.
- **app_namespace** (*str*) –Application namespace for the URL entries being included

See [Including other URLconfs](#) and [URL namespaces and included URLconfs](#).

6.26.4 `register_converter()`

`register_converter(converter, type_name)`

The function for registering a converter for use in [path\(\)](#) routes.

The `converter` argument is a converter class, and `type_name` is the converter name to use in path patterns. See [Registering custom path converters](#) for an example.

6.27 `django.conf.urls` functions for use in URLconfs

6.27.1 `static()`

`static.static(prefix, view=django.views.static.serve, **kwargs)`

Helper function to return a URL pattern for serving files in debug mode:

```
from django.conf import settings
from django.conf.urls.static import static

urlpatterns = [
    # ... the rest of your URLconf goes here ...
] + static(settings.MEDIA_URL, document_root=settings.MEDIA_ROOT)
```

6.27.2 handler400

handler400

A callable, or a string representing the full Python import path to the view that should be called if the HTTP client has sent a request that caused an error condition and a response with a status code of 400.

By default, this is `django.views.defaults.bad_request()`. If you implement a custom view, be sure it accepts `request` and `exception` arguments and returns an `HttpResponseBadRequest`.

6.27.3 handler403

handler403

A callable, or a string representing the full Python import path to the view that should be called if the user doesn't have the permissions required to access a resource.

By default, this is `django.views.defaults.permission_denied()`. If you implement a custom view, be sure it accepts `request` and `exception` arguments and returns an `HttpResponseForbidden`.

6.27.4 handler404

handler404

A callable, or a string representing the full Python import path to the view that should be called if none of the URL patterns match.

By default, this is `django.views.defaults.page_not_found()`. If you implement a custom view, be sure it accepts `request` and `exception` arguments and returns an `HttpResponseNotFound`.

6.27.5 handler500

handler500

A callable, or a string representing the full Python import path to the view that should be called in case of server errors. Server errors happen when you have runtime errors in view code.

By default, this is `django.views.defaults.server_error()`. If you implement a custom view, be sure it accepts a `request` argument and returns an `HttpResponseServerError`.

6.28 Django Utils

This document covers all stable modules in `django.utils`. Most of the modules in `django.utils` are designed for internal use and only the following parts can be considered stable and thus backwards compatible as per the [internal release deprecation policy](#).

6.28.1 django.utils.cache

This module contains helper functions for controlling HTTP caching. It does so by managing the `Vary` header of responses. It includes functions to patch the header of response objects directly and decorators that change functions to do that header-patching themselves.

For information on the `Vary` header, see [RFC 9110#section-12.5.5](#).

Essentially, the `Vary` HTTP header defines which headers a cache should take into account when building its cache key. Requests with the same path but different header content for headers named in `Vary` need to get different cache keys to prevent delivery of wrong content.

For example, [internationalization](#) middleware would need to distinguish caches by the `Accept-language` header.

`patch_cache_control(response, **kwargs)`

This function patches the `Cache-Control` header by adding all keyword arguments to it. The transformation is as follows:

- All keyword parameter names are turned to lowercase, and underscores are converted to hyphens.
- If the value of a parameter is `True` (exactly `True`, not just a true value), only the parameter name is added to the header.
- All other parameters are added with their value, after applying `str()` to it.

`get_max_age(response)`

Returns the max-age from the response `Cache-Control` header as an integer (or `None` if it wasn't found or wasn't an integer).

patch_response_headers(response, cache_timeout=None)

Adds some useful headers to the given `HttpResponse` object:

- Expires
- Cache-Control

Each header is only added if it isn't already set.

`cache_timeout` is in seconds. The `CACHE_MIDDLEWARE_SECONDS` setting is used by default.

add_never_cache_headers(response)

Adds an Expires header to the current date/time.

Adds a Cache-Control: max-age=0, no-cache, no-store, must-revalidate, private header to a response to indicate that a page should never be cached.

Each header is only added if it isn't already set.

patch_vary_headers(response, newheaders)

Adds (or updates) the Vary header in the given `HttpResponse` object. `newheaders` is a list of header names that should be in Vary. If `headers` contains an asterisk, then Vary header will consist of a single asterisk '*', according to [RFC 9110#section-12.5.5](#). Otherwise, existing headers in Vary aren't removed.

get_cache_key(request, key_prefix=None, method='GET', cache=None)

Returns a cache key based on the request path. It can be used in the request phase because it pulls the list of headers to take into account from the global path registry and uses those to build a cache key to check against.

If there is no headerlist stored, the page needs to be rebuilt, so this function returns `None`.

learn_cache_key(request, response, cache_timeout=None, key_prefix=None, cache=None)

Learns what headers to take into account for some request path from the response object. It stores those headers in a global path registry so that later access to that path will know what headers to take into account without building the response object itself. The headers are named in the Vary header of the response, but we want to prevent response generation.

The list of headers to use for cache key generation is stored in the same cache as the pages themselves. If the cache ages some data out of the cache, this means that we have to build the response once to get at the Vary header and so at the list of headers to use for the cache key.

6.28.2 `django.utils.dateparse`

The functions defined in this module share the following properties:

- They accept strings in ISO 8601 date/time formats (or some close alternatives) and return objects from the corresponding classes in Python's `datetime` module.
- They raise `ValueError` if their input is well formatted but isn't a valid date or time.
- They return `None` if it isn't well formatted at all.
- They accept up to picosecond resolution in input, but they truncate it to microseconds, since that's what Python supports.

`parse_date(value)`

Parses a string and returns a `datetime.date`.

`parse_time(value)`

Parses a string and returns a `datetime.time`.

UTC offsets aren't supported; if `value` describes one, the result is `None`.

`parse_datetime(value)`

Parses a string and returns a `datetime.datetime`.

UTC offsets are supported; if `value` describes one, the result's `tzinfo` attribute is a `datetime.timezone` instance.

`parse_duration(value)`

Parses a string and returns a `datetime.timedelta`.

Expects data in the format "DD HH:MM:SS.uuuuuu", "DD HH:MM:SS,uuuuuu", or as specified by ISO 8601 (e.g. P4DT1H15M20S which is equivalent to 4 1:15:20) or PostgreSQL's day-time interval format (e.g. 3 days 04:05:06).

6.28.3 `django.utils.decorators`

`method_decorator(decorator, name='')`

Converts a function decorator into a method decorator. It can be used to decorate methods or classes; in the latter case, `name` is the name of the method to be decorated and is required.

`decorator` may also be a list or tuple of functions. They are wrapped in reverse order so that the call order is the order in which the functions appear in the list/tuple.

See [decorating class based views](#) for example usage.

`decorator_from_middleware(middleware_class)`

Given a middleware class, returns a view decorator. This lets you use middleware functionality on a per-view basis. The middleware is created with no params passed.

It assumes middleware that's compatible with the old style of Django 1.9 and earlier (having methods like `process_request()`, `process_exception()`, and `process_response()`).

`decorator_from_middleware_with_args(middleware_class)`

Like `decorator_from_middleware`, but returns a function that accepts the arguments to be passed to the `middleware_class`. For example, the `cache_page()` decorator is created from the `CacheMiddleware` like this:

```
cache_page = decorator_from_middleware_with_args(CacheMiddleware)

@cache_page(3600)
def my_view(request):
    pass
```

`sync_only_middleware(middleware)`

Marks a middleware as [synchronous-only](#). (The default in Django, but this allows you to future-proof if the default ever changes in a future release.)

`async_only_middleware(middleware)`

Marks a middleware as [asynchronous-only](#). Django will wrap it in an asynchronous event loop when it is called from the WSGI request path.

`sync_and_async_middleware(middleware)`

Marks a middleware as [sync and async compatible](#), this allows to avoid converting requests. You must implement detection of the current request type to use this decorator. See [asynchronous middleware documentation](#) for details.

6.28.4 `django.utils.encoding`

`smart_str(s, encoding='utf-8', strings_only=False, errors='strict')`

Returns a `str` object representing arbitrary object `s`. Treats bytestrings using the `encoding` codec.

If `strings_only` is `True`, don't convert (some) non-string-like objects.

`is_protected_type(obj)`

Determine if the object instance is of a protected type.

Objects of protected types are preserved as-is when passed to `force_str(strings_only=True)`.

`force_str(s, encoding='utf-8', strings_only=False, errors='strict')`

Similar to `smart_str()`, except that lazy instances are resolved to strings, rather than kept as lazy objects.

If `strings_only` is `True`, don't convert (some) non-string-like objects.

smart_bytes(s, encoding='utf-8', strings_only=False, errors='strict')

Returns a bytestring version of arbitrary object *s*, encoded as specified in *encoding*.

If *strings_only* is *True*, don't convert (some) non-string-like objects.

force_bytes(s, encoding='utf-8', strings_only=False, errors='strict')

Similar to *smart_bytes*, except that lazy instances are resolved to bytestrings, rather than kept as lazy objects.

If *strings_only* is *True*, don't convert (some) non-string-like objects.

iri_to_uri(iri)

Convert an Internationalized Resource Identifier (IRI) portion to a URI portion that is suitable for inclusion in a URL.

This is the algorithm from section 3.1 of [RFC 3987#section-3.1](#), slightly simplified since the input is assumed to be a string rather than an arbitrary byte stream.

Takes an IRI (string or UTF-8 bytes) and returns a string containing the encoded result.

uri_to_iri(uri)

Converts a Uniform Resource Identifier into an Internationalized Resource Identifier.

This is an algorithm from section 3.2 of [RFC 3987#section-3.2](#).

Takes a URI in ASCII bytes and returns a string containing the encoded result.

filepath_to_uri(path)

Convert a file system path to a URI portion that is suitable for inclusion in a URL. The path is assumed to be either UTF-8 bytes, string, or a [Path](#).

This method will encode certain characters that would normally be recognized as special characters for URIs. Note that this method does not encode the `'` character, as it is a valid character within URIs. See `encodeURIComponent()` JavaScript function for more details.

Returns an ASCII string containing the encoded result.

escape_uri_path(path)

Escapes the unsafe characters from the path portion of a Uniform Resource Identifier (URI).

6.28.5 django.utils.feedgenerator

Sample usage:

```
>>> from django.utils import feedgenerator
>>> feed = feedgenerator.Rss201rev2Feed(
...     title="Poynter E-Media Tidbits",
...     link="http://www.poynter.org/column.asp?id=31",
```

(continues on next page)

(continued from previous page)

```

...     description="A group blog by the sharpest minds in online media/journalism/publishing.",
...     language="en",
... )
>>> feed.add_item(
...     title="Hello",
...     link="http://www.holovaty.com/test/",
...     description="Testing.",
... )
>>> with open("test.rss", "w") as fp:
...     feed.write(fp, "utf-8")
...

```

For simplifying the selection of a generator use `feedgenerator.DefaultFeed` which is currently `Rss201rev2Feed`

For definitions of the different versions of RSS, see: <https://web.archive.org/web/20110718035220/http://diveintomark.org/archives/2004/02/04/incompatible-rss>

get_tag_uri(url, date)

Creates a TagURI.

See <https://web.archive.org/web/20110514113830/http://diveintomark.org/archives/2004/05/28/howto-atom-id>

SyndicationFeed

class SyndicationFeed

Base class for all syndication feeds. Subclasses should provide `write()`.

__init__(title, link, description, language=None, author_email=None, author_name=None, author_link=None, subtitle=None, categories=None, feed_url=None, feed_copyright=None, feed_guid=None, ttl=None, **kwargs)

Initialize the feed with the given dictionary of metadata, which applies to the entire feed.

Any extra keyword arguments you pass to `__init__` will be stored in `self.feed`.

All parameters should be strings, except `categories`, which should be a sequence of strings.

add_item(title, link, description, author_email=None, author_name=None, author_link=None, pubdate=None, comments=None, unique_id=None, categories=(), item_copyright=None, ttl=None, updateddate=None, enclosures=None, **kwargs)

Adds an item to the feed. All args are expected to be strings except `pubdate` and `updateddate`, which are `datetime.datetime` objects, and `enclosures`, which is a list of `Enclosure` instances.

num_items()

root_attributes()

Return extra attributes to place on the root (i.e. feed/channel) element. Called from **write()**.

add_root_elements(handler)

Add elements in the root (i.e. feed/channel) element. Called from **write()**.

item_attributes(item)

Return extra attributes to place on each item (i.e. item/entry) element.

add_item_elements(handler, item)

Add elements on each item (i.e. item/entry) element.

write(outfile, encoding)

Outputs the feed in the given encoding to **outfile**, which is a file-like object. Subclasses should override this.

writeString(encoding)

Returns the feed in the given encoding as a string.

latest_post_date()

Returns the latest **pubdate** or **updateddate** for all items in the feed. If no items have either of these attributes this returns the current UTC date/time.

Enclosure

class Enclosure

Represents an RSS enclosure

RssFeed

class RssFeed(SyndicationFeed)

Rss201rev2Feed

class Rss201rev2Feed(RssFeed)

Spec: <https://cyber.harvard.edu/rss/rss.html>

RssUserland091Feed

```
class RssUserland091Feed(RssFeed)
    Spec: http://backend.userland.com/rss091
```

Atom1Feed

```
class Atom1Feed(SyndicationFeed)
    Spec: RFC 4287
```

6.28.6 django.utils.functional

```
class cached_property(func, name=None)
```

The `@cached_property` decorator caches the result of a method with a single `self` argument as a property. The cached result will persist as long as the instance does, so if the instance is passed around and the function subsequently invoked, the cached result will be returned.

Consider a typical case, where a view might need to call a model's method to perform some computation, before placing the model instance into the context, where the template might invoke the method once more:

```
# the model
class Person(models.Model):
    def friends(self):
        # expensive computation
        ...
        return friends

# in the view:
if person.friends():
    ...
```

And in the template you would have:

```
{% for friend in person.friends %}
```

Here, `friends()` will be called twice. Since the instance `person` in the view and the template are the same, decorating the `friends()` method with `@cached_property` can avoid that:

```
from django.utils.functional import cached_property
```

(continues on next page)

(continued from previous page)

```
class Person(models.Model):
    @cached_property
    def friends(self):
        ...
```

Note that as the method is now a property, in Python code it will need to be accessed appropriately:

```
# in the view:
if person.friends:
    ...
```

The cached value can be treated like an ordinary attribute of the instance:

```
# clear it, requiring re-computation next time it's called
del person.friends # or delattr(person, "friends")

# set a value manually, that will persist on the instance until cleared
person.friends = ["Huckleberry Finn", "Tom Sawyer"]
```

Because of the way the [descriptor protocol](#) works, using `del` (or `delattr`) on a `cached_property` that hasn't been accessed raises `AttributeError`.

As well as offering potential performance advantages, `@cached_property` can ensure that an attribute's value does not change unexpectedly over the life of an instance. This could occur with a method whose computation is based on `datetime.now()`, or if a change were saved to the database by some other process in the brief interval between subsequent invocations of a method on the same instance.

You can make cached properties of methods. For example, if you had an expensive `get_friends()` method and wanted to allow calling it without retrieving the cached value, you could write:

```
friends = cached_property(get_friends)
```

While `person.get_friends()` will recompute the friends on each call, the value of the cached property will persist until you delete it as described above:

```
x = person.friends # calls first time
y = person.get_friends() # calls again
z = person.friends # does not call
x is z # is True
```

Deprecated since version 4.1: The `name` parameter is deprecated and will be removed in Django 5.0 as it's unnecessary as of Python 3.6.

```
class classproperty(method=None)
```

Similar to `@classmethod`, the `@classproperty` decorator converts the result of a method with a single

`cls` argument into a property that can be accessed directly from the class.

keep_lazy(func, *resultclasses)

Django offers many utility functions (particularly in `django.utils`) that take a string as their first argument and do something to that string. These functions are used by template filters as well as directly in other code.

If you write your own similar functions and deal with translations, you'll face the problem of what to do when the first argument is a lazy translation object. You don't want to convert it to a string immediately, because you might be using this function outside of a view (and hence the current thread's locale setting will not be correct).

For cases like this, use the `django.utils.functional.keep_lazy()` decorator. It modifies the function so that if it's called with a lazy translation as one of its arguments, the function evaluation is delayed until it needs to be converted to a string.

For example:

```
from django.utils.functional import keep_lazy, keep_lazy_text

def fancy_utility_function(s, *args, **kwargs):
    # Do some conversion on string 's'
    ...

fancy_utility_function = keep_lazy(str)(fancy_utility_function)

# Or more succinctly:
@keep_lazy(str)
def fancy_utility_function(s, *args, **kwargs):
    ...
```

The `keep_lazy()` decorator takes a number of extra arguments (`*args`) specifying the type(s) that the original function can return. A common use case is to have functions that return text. For these, you can pass the `str` type to `keep_lazy` (or use the `keep_lazy_text()` decorator described in the next section).

Using this decorator means you can write your function and assume that the input is a proper string, then add support for lazy translation objects at the end.

keep_lazy_text(func)

A shortcut for `keep_lazy(str)(func)`.

If you have a function that returns text and you want to be able to take lazy arguments while delaying their evaluation, you can use this decorator:

```
from django.utils.functional import keep_lazy, keep_lazy_text

# Our previous example was:
@keep_lazy(str)
def fancy_utility_function(s, *args, **kwargs):
    ...

# Which can be rewritten as:
@keep_lazy_text
def fancy_utility_function(s, *args, **kwargs):
    ...
```

6.28.7 `django.utils.html`

Usually you should build up HTML using Django's templates to make use of its autoescape mechanism, using the utilities in `django.utils.safestring` where appropriate. This module provides some additional low level utilities for escaping HTML.

escape(text)

Returns the given text with ampersands, quotes and angle brackets encoded for use in HTML. The input is first coerced to a string and the output has `mark_safe()` applied.

conditional_escape(text)

Similar to `escape()`, except that it doesn't operate on preescaped strings, so it will not double escape.

format_html(format_string, *args, **kwargs)

This is similar to `str.format()`, except that it is appropriate for building up HTML fragments. The first argument `format_string` is not escaped but all other args and kwargs are passed through `conditional_escape()` before being passed to `str.format()`. Finally, the output has `mark_safe()` applied.

For the case of building up small HTML fragments, this function is to be preferred over string interpolation using `%` or `str.format()` directly, because it applies escaping to all arguments - just like the template system applies escaping by default.

So, instead of writing:

```
mark_safe(
    "%s <b>%s</b> %s"
    % (
        some_html,
        escape(some_text),
```

(continues on next page)

(continued from previous page)

```

        escape(some_other_text),
    )
)

```

You should instead use:

```

format_html(
    "{} <b>{}</b> {}".format(
        mark_safe(some_html),
        some_text,
        some_other_text,
    )
)

```

This has the advantage that you don't need to apply `escape()` to each argument and risk a bug and an XSS vulnerability if you forget one.

Note that although this function uses `str.format()` to do the interpolation, some of the formatting options provided by `str.format()` (e.g. number formatting) will not work, since all arguments are passed through `conditional_escape()` which (ultimately) calls `force_str()` on the values.

format_html_join(sep, format_string, args_generator)

A wrapper of `format_html()`, for the common case of a group of arguments that need to be formatted using the same format string, and then joined using `sep`. `sep` is also passed through `conditional_escape()`.

`args_generator` should be an iterator that returns the sequence of `args` that will be passed to `format_html()`. For example:

```
format_html_join("\n", "<li>{} {}</li>", ((u.first_name, u.last_name) for u in users))
```

json_script(value, element_id=None, encoder=None)

Escapes all HTML/XML special characters with their Unicode escapes, so `value` is safe for use with JavaScript. Also wraps the escaped JSON in a `<script>` tag. If the `element_id` parameter is not `None`, the `<script>` tag is given the passed id. For example:

```

>>> json_script({"hello": "world"}, element_id="hello-data")
'<script id="hello-data" type="application/json">{"hello": "world"}</script>'

```

The `encoder`, which defaults to `django.core.serializers.json.DjangoJSONEncoder`, will be used to serialize the data. See [JSON serialization](#) for more details about this serializer.

In older versions, the `element_id` argument was required.

The `encoder` argument was added.

strip_tags(value)

Tries to remove anything that looks like an HTML tag from the string, that is anything contained within `<>`.

Absolutely NO guarantee is provided about the resulting string being HTML safe. So NEVER mark safe the result of a `strip_tag` call without escaping it first, for example with `escape()`.

For example:

```
strip_tags(value)
```

If `value` is `"<b>Joel</b> <button>is</button> a <span>slug</span>"` the return value will be `"Joel is a slug"`.

If you are looking for a more robust solution, consider using a third-party HTML sanitizing tool.

html_safe()

The `__html__()` method on a class helps non-Django templates detect classes whose output doesn't require HTML escaping.

This decorator defines the `__html__()` method on the decorated class by wrapping `__str__()` in `mark_safe()`. Ensure the `__str__()` method does indeed return text that doesn't require HTML escaping.

6.28.8 django.utils.http

urlencode(query, doseq=False)

A version of Python's `urllib.parse.urlencode()` function that can operate on `MultiValueDict` and non-string values.

http_date(epoch_seconds=None)

Formats the time to match the [RFC 1123#section-5.2.14](#) date format as specified by HTTP [RFC 9110#section-5.6.7](#).

Accepts a floating point number expressed in seconds since the epoch in UTC—such as that outputted by `time.time()`. If set to `None`, defaults to the current time.

Outputs a string in the format `Wdy, DD Mon YYYY HH:MM:SS GMT`.

content_disposition_header(as_attachment, filename)

Constructs a `Content-Disposition` HTTP header value from the given `filename` as specified by [RFC 6266](#). Returns `None` if `as_attachment` is `False` and `filename` is `None`, otherwise returns a string suitable for the `Content-Disposition` HTTP header.

base36_to_int(s)

Converts a base 36 string to an integer.

`int_to_base36(i)`

Converts a positive integer to a base 36 string.

`urlsafe_base64_encode(s)`

Encodes a bytestring to a base64 string for use in URLs, stripping any trailing equal signs.

`urlsafe_base64_decode(s)`

Decodes a base64 encoded string, adding back any trailing equal signs that might have been stripped.

6.28.9 `django.utils.module_loading`

Functions for working with Python modules.

`import_string(dotted_path)`

Imports a dotted module path and returns the attribute/class designated by the last name in the path. Raises `ImportError` if the import failed. For example:

```
from django.utils.module_loading import import_string

ValidationError = import_string("django.core.exceptions.ValidationError")
```

is equivalent to:

```
from django.core.exceptions import ValidationError
```

6.28.10 `django.utils.safestring`

Functions and classes for working with “safe strings” : strings that can be displayed safely without further escaping in HTML. Marking something as a “safe string” means that the producer of the string has already turned characters that should not be interpreted by the HTML engine (e.g. ‘<’) into the appropriate entities.

`class SafeString`

A `str` subclass that has been specifically marked as “safe” (requires no further escaping) for HTML output purposes.

`mark_safe(s)`

Explicitly mark a string as safe for (HTML) output purposes. The returned object can be used everywhere a string is appropriate.

Can be called multiple times on a single string.

Can also be used as a decorator.

For building up fragments of HTML, you should normally be using `django.utils.html.format_html()` instead.

String marked safe will become unsafe again if modified. For example:

```
>>> mystr = "<b>Hello World</b>  "
>>> mystr = mark_safe(mystr)
>>> type(mystr)
<class 'django.utils.safestring.SafeString'>

>>> mystr = mystr.strip()  # removing whitespace
>>> type(mystr)
<type 'str'>
```

6.28.11 django.utils.text

`format_lazy(format_string, *args, **kwargs)`

A version of `str.format()` for when `format_string`, `args`, and/or `kwargs` contain lazy objects. The first argument is the string to be formatted. For example:

```
from django.utils.text import format_lazy
from django.utils.translation import pgettext_lazy

urlpatterns = [
    path(
        format_lazy("{person}/<int:pk>/", person=pgettext_lazy("URL", "person")),
        PersonDetailView.as_view(),
    ),
]
```

This example allows translators to translate part of the URL. If “person” is translated to “persona”, the regular expression will match `persona/(?P<pk>\d+)/$`, e.g. `persona/5/`.

`slugify(value, allow_unicode=False)`

Converts a string to a URL slug by:

1. Converting to ASCII if `allow_unicode` is `False` (the default).
2. Converting to lowercase.
3. Removing characters that aren't alphanumerics, underscores, hyphens, or whitespace.
4. Replacing any whitespace or repeated dashes with single dashes.
5. Removing leading and trailing whitespace, dashes, and underscores.

For example:

```
>>> slugify(" Joel is a slug ")
'joel-is-a-slug'
```

If you want to allow Unicode characters, pass `allow_unicode=True`. For example:

```
>>> slugify("你好 World", allow_unicode=True)
'你好-world'
```

6.28.12 `django.utils.timezone`

utc

`tzinfo` instance that represents UTC.

Deprecated since version 4.1: This is an alias to `datetime.timezone.utc`. Use `datetime.timezone.utc` directly.

`get_fixed_timezone(offset)`

Returns a `tzinfo` instance that represents a time zone with a fixed offset from UTC.

`offset` is a `datetime.timedelta` or an integer number of minutes. Use positive values for time zones east of UTC and negative values for west of UTC.

`get_default_timezone()`

Returns a `tzinfo` instance that represents the default time zone.

`get_default_timezone_name()`

Returns the name of the default time zone.

`get_current_timezone()`

Returns a `tzinfo` instance that represents the current time zone.

`get_current_timezone_name()`

Returns the name of the current time zone.

`activate(timezone)`

Sets the current time zone. The `timezone` argument must be an instance of a `tzinfo` subclass or a time zone name.

`deactivate()`

Unsets the current time zone.

`override(timezone)`

This is a Python context manager that sets the current time zone on entry with `activate()`, and restores the previously active time zone on exit. If the `timezone` argument is `None`, the current time zone is unset on entry with `deactivate()` instead.

`override` is also usable as a function decorator.

`localtime(value=None, timezone=None)`

Converts an aware `datetime` to a different time zone, by default the `current time zone`.

When `value` is omitted, it defaults to `now()`.

This function doesn't work on naive datetimes; use `make_aware()` instead.

`localdate(value=None, timezone=None)`

Uses `localtime()` to convert an aware `datetime` to a `date()` in a different time zone, by default the `current time zone`.

When `value` is omitted, it defaults to `now()`.

This function doesn't work on naive datetimes.

`now()`

Returns a `datetime` that represents the current point in time. Exactly what's returned depends on the value of `USE_TZ`:

- If `USE_TZ` is `False`, this will be a `naive` datetime (i.e. a datetime without an associated timezone) that represents the current time in the system's local timezone.
- If `USE_TZ` is `True`, this will be an `aware` datetime representing the current time in UTC. Note that `now()` will always return times in UTC regardless of the value of `TIME_ZONE`; you can use `localtime()` to get the time in the current time zone.

`is_aware(value)`

Returns `True` if `value` is aware, `False` if it is naive. This function assumes that `value` is a `datetime`.

`is_naive(value)`

Returns `True` if `value` is naive, `False` if it is aware. This function assumes that `value` is a `datetime`.

`make_aware(value, timezone=None, is_dst=None)`

Returns an aware `datetime` that represents the same point in time as `value` in `timezone`, `value` being a naive `datetime`. If `timezone` is set to `None`, it defaults to the `current time zone`.

Deprecated since version 4.0: When using `pytz`, the `pytz.AmbiguousTimeError` exception is raised if you try to make `value` aware during a DST transition where the same time occurs twice (when reverting from DST). Setting `is_dst` to `True` or `False` will avoid the exception by choosing if the time is pre-transition or post-transition respectively.

When using `pytz`, the `pytz.NonExistentTimeError` exception is raised if you try to make `value` aware during a DST transition such that the time never occurred. For example, if the 2:00 hour is skipped during a DST transition, trying to make 2:30 aware in that time zone will raise an exception. To avoid that you can use `is_dst` to specify how `make_aware()` should interpret such a nonexistent time. If `is_dst=True` then the above time would be interpreted as 2:30 DST time (equivalent to 1:30 local time). Conversely, if `is_dst=False` the time would be interpreted as 2:30 standard time (equivalent to 3:30 local time).

The `is_dst` parameter has no effect when using non-pytz timezone implementations.

The `is_dst` parameter is deprecated and will be removed in Django 5.0.

`make_naive`(value, timezone=None)

Returns a naive `datetime` that represents in `timezone` the same point in time as `value`, `value` being an aware `datetime`. If `timezone` is set to `None`, it defaults to the [current time zone](#).

6.28.13 `django.utils.translation`

For a complete discussion on the usage of the following see the [translation documentation](#).

`gettext`(message)

Translates `message` and returns it as a string.

`pgettext`(context, message)

Translates `message` given the `context` and returns it as a string.

For more information, see [Contextual markers](#).

`gettext_lazy`(message)

`pgettext_lazy`(context, message)

Same as the non-lazy versions above, but using lazy execution.

See [lazy translations documentation](#).

`gettext_noop`(message)

Marks strings for translation but doesn't translate them now. This can be used to store strings in global variables that should stay in the base language (because they might be used externally) and will be translated later.

`ngettext`(singular, plural, number)

Translates `singular` and `plural` and returns the appropriate string based on `number`.

`npgettext`(context, singular, plural, number)

Translates `singular` and `plural` and returns the appropriate string based on `number` and the `context`.

`ngettext_lazy`(singular, plural, number)

`npgettext_lazy`(context, singular, plural, number)

Same as the non-lazy versions above, but using lazy execution.

See [lazy translations documentation](#).

`activate`(language)

Fetches the translation object for a given language and activates it as the current translation object for the current thread.

deactivate()

Deactivates the currently active translation object so that further `_` calls will resolve against the default translation object, again.

deactivate_all()

Makes the active translation object a `NullTranslations()` instance. This is useful when we want delayed translations to appear as the original string for some reason.

override(language, deactivate=False)

A Python context manager that uses `django.utils.translation.activate()` to fetch the translation object for a given language, activates it as the translation object for the current thread and reactivates the previous active language on exit. Optionally, it can deactivate the temporary translation on exit with `django.utils.translation.deactivate()` if the `deactivate` argument is `True`. If you pass `None` as the language argument, a `NullTranslations()` instance is activated within the context.

`override` is also usable as a function decorator.

check_for_language(lang_code)

Checks whether there is a global language file for the given language code (e.g. `'fr'`, `'pt_BR'`). This is used to decide whether a user-provided language is available.

get_language()

Returns the currently selected language code. Returns `None` if translations are temporarily deactivated (by `deactivate_all()` or when `None` is passed to `override()`).

get_language_bidi()

Returns selected language' s BiDi layout:

- `False` = left-to-right layout
- `True` = right-to-left layout

get_language_from_request(request, check_path=False)

Analyzes the request to find what language the user wants the system to show. Only languages listed in `settings.LANGUAGES` are taken into account. If the user requests a sublanguage where we have a main language, we send out the main language.

If `check_path` is `True`, the function first checks the requested URL for whether its path begins with a language code listed in the `LANGUAGES` setting.

get_supported_language_variant(lang_code, strict=False)

Returns `lang_code` if it' s in the `LANGUAGES` setting, possibly selecting a more generic variant. For example, `'es'` is returned if `lang_code` is `'es-ar'` and `'es'` is in `LANGUAGES` but `'es-ar'` isn' t.

If `strict` is `False` (the default), a country-specific variant may be returned when neither the language code nor its generic variant is found. For example, if only `'es-co'` is in `LANGUAGES`, that' s returned for `lang_codes` like `'es'` and `'es-ar'`. Those matches aren' t returned if `strict=True`.

Raises `LookupError` if nothing is found.

`to_locale(language)`

Turns a language name (en-us) into a locale name (en_US).

`templatize(src)`

Turns a Django template into something that is understood by `xgettext`. It does so by translating the Django translation tags into standard `gettext` function invocations.

6.29 Validators

6.29.1 Writing validators

A validator is a callable that takes a value and raises a `ValidationError` if it doesn't meet some criteria. Validators can be useful for reusing validation logic between different types of fields.

For example, here's a validator that only allows even numbers:

```
from django.core.exceptions import ValidationError
from django.utils.translation import gettext_lazy as _

def validate_even(value):
    if value % 2 != 0:
        raise ValidationError(
            _("%(value)s is not an even number"),
            params={"value": value},
        )
```

You can add this to a model field via the field's `validators` argument:

```
from django.db import models

class MyModel(models.Model):
    even_field = models.IntegerField(validators=[validate_even])
```

Because values are converted to Python before validators are run, you can even use the same validator with forms:

```
from django import forms
```

(continues on next page)

(continued from previous page)

```
class MyForm(forms.Form):
    even_field = forms.IntegerField(validators=[validate_even])
```

You can also use a class with a `__call__()` method for more complex or configurable validators. *RegexValidator*, for example, uses this technique. If a class-based validator is used in the *validators* model field option, you should make sure it is *serializable by the migration framework* by adding `deconstruct()` and `__eq__()` methods.

6.29.2 How validators are run

See the *form validation* for more information on how validators are run in forms, and *Validating objects* for how they're run in models. Note that validators will not be run automatically when you save a model, but if you are using a *ModelForm*, it will run your validators on any fields that are included in your form. See the *ModelForm documentation* for information on how model validation interacts with forms.

6.29.3 Built-in validators

The *django.core.validators* module contains a collection of callable validators for use with model and form fields. They're used internally but are available for use with your own fields, too. They can be used in addition to, or in lieu of custom `field.clean()` methods.

RegexValidator

```
class RegexValidator(regex=None, message=None, code=None, inverse_match=None, flags=0)
```

Parameters

- **regex** –If not `None`, overrides *regex*. Can be a regular expression string or a pre-compiled regular expression.
- **message** –If not `None`, overrides *message*.
- **code** –If not `None`, overrides *code*.
- **inverse_match** –If not `None`, overrides *inverse_match*.
- **flags** –If not `None`, overrides *flags*. In that case, *regex* must be a regular expression string, or *TypeError* is raised.

A *RegexValidator* searches the provided value for a given regular expression with `re.search()`. By default, raises a *ValidationError* with *message* and *code* if a match is not found. Its behavior can be inverted by setting *inverse_match* to `True`, in which case the *ValidationError* is raised when a match is found.

regex

The regular expression pattern to search for within the provided value, using `re.search()`. This may be a string or a pre-compiled regular expression created with `re.compile()`. Defaults to the empty string, which will be found in every possible value.

message

The error message used by `ValidationError` if validation fails. Defaults to "Enter a valid value".

code

The error code used by `ValidationError` if validation fails. Defaults to "invalid".

inverse_match

The match mode for `regex`. Defaults to False.

flags

The `regex flags` used when compiling the regular expression string `regex`. If `regex` is a pre-compiled regular expression, and `flags` is overridden, `TypeError` is raised. Defaults to 0.

EmailValidator

```
class EmailValidator(message=None, code=None, allowlist=None)
```

Parameters

- **message** –If not None, overrides `message`.
- **code** –If not None, overrides `code`.
- **allowlist** –If not None, overrides `allowlist`.

An `EmailValidator` ensures that a value looks like an email, and raises a `ValidationError` with `message` and `code` if it doesn't. Values longer than 320 characters are always considered invalid.

message

The error message used by `ValidationError` if validation fails. Defaults to "Enter a valid email address".

code

The error code used by `ValidationError` if validation fails. Defaults to "invalid".

allowlist

Allowlist of email domains. By default, a regular expression (the `domain_regex` attribute) is used to validate whatever appears after the @ sign. However, if that string appears in the `allowlist`, this validation is bypassed. If not provided, the default `allowlist` is `['localhost']`. Other domains that don't contain a dot won't pass validation, so you'd need to add them to the `allowlist` as necessary.

In older versions, values longer than 320 characters could be considered valid.

`URLValidator`

class `URLValidator`(schemes=None, regex=None, message=None, code=None)

A *RegexValidator* subclass that ensures a value looks like a URL, and raises an error code of 'invalid' if it doesn't. Values longer than *max_length* characters are always considered invalid.

Loopback addresses and reserved IP spaces are considered valid. Literal IPv6 addresses ([RFC 3986#section-3.2.2](#)) and Unicode domains are both supported.

In addition to the optional arguments of its parent *RegexValidator* class, `URLValidator` accepts an extra optional attribute:

schemes

URL/URI scheme list to validate against. If not provided, the default list is ['http', 'https', 'ftp', 'ftps']. As a reference, the IANA website provides a full list of [valid URI schemes](#).

max_length

The maximum length of values that could be considered valid. Defaults to 2048 characters.

In older versions, values longer than 2048 characters could be considered valid.

`validate_email`

`validate_email`

An *EmailValidator* instance without any customizations.

`validate_slug`

`validate_slug`

A *RegexValidator* instance that ensures a value consists of only letters, numbers, underscores or hyphens.

`validate_unicode_slug`

`validate_unicode_slug`

A *RegexValidator* instance that ensures a value consists of only Unicode letters, numbers, underscores, or hyphens.

`validate_ipv4_address`

`validate_ipv4_address`

A *RegexValidator* instance that ensures a value looks like an IPv4 address.

`validate_ipv6_address`

`validate_ipv6_address`

Uses `django.utils.ipv6` to check the validity of an IPv6 address.

`validate_ipv46_address`

`validate_ipv46_address`

Uses both `validate_ipv4_address` and `validate_ipv6_address` to ensure a value is either a valid IPv4 or IPv6 address.

`validate_comma_separated_integer_list`

`validate_comma_separated_integer_list`

A *RegexValidator* instance that ensures a value is a comma-separated list of integers.

`int_list_validator`

`int_list_validator(sep=',', message=None, code='invalid', allow_negative=False)`

Returns a *RegexValidator* instance that ensures a string consists of integers separated by `sep`. It allows negative integers when `allow_negative` is `True`.

`MaxValueValidator`

`class MaxValueValidator(limit_value, message=None)`

Raises a *ValidationError* with a code of `'max_value'` if `value` is greater than `limit_value`, which may be a callable.

MinValueValidator

```
class MinValueValidator(limit_value, message=None)
```

Raises a *ValidationError* with a code of 'min_value' if value is less than limit_value, which may be a callable.

MaxLengthValidator

```
class MaxLengthValidator(limit_value, message=None)
```

Raises a *ValidationError* with a code of 'max_length' if the length of value is greater than limit_value, which may be a callable.

MinLengthValidator

```
class MinLengthValidator(limit_value, message=None)
```

Raises a *ValidationError* with a code of 'min_length' if the length of value is less than limit_value, which may be a callable.

DecimalValidator

```
class DecimalValidator(max_digits, decimal_places)
```

Raises *ValidationError* with the following codes:

- 'max_digits' if the number of digits is larger than max_digits.
- 'max_decimal_places' if the number of decimals is larger than decimal_places.
- 'max_whole_digits' if the number of whole digits is larger than the difference between max_digits and decimal_places.

FileExtensionValidator

```
class FileExtensionValidator(allowed_extensions, message, code)
```

Raises a *ValidationError* with a code of 'invalid_extension' if the extension of value.name (value is a *File*) isn't found in allowed_extensions. The extension is compared case-insensitively with allowed_extensions.

Warning: Don't rely on validation of the file extension to determine a file's type. Files can be renamed to have any extension no matter what data they contain.

`validate_image_file_extension`

`validate_image_file_extension`

Uses Pillow to ensure that `value.name` (value is a *File*) has a valid image extension.

ProhibitNullCharactersValidator

`class ProhibitNullCharactersValidator(message=None, code=None)`

Raises a *ValidationError* if `str(value)` contains one or more null characters (`'\x00'`).

Parameters

- **message** –If not `None`, overrides *message*.
- **code** –If not `None`, overrides *code*.

message

The error message used by *ValidationError* if validation fails. Defaults to "Null characters are not allowed."

code

The error code used by *ValidationError* if validation fails. Defaults to "null_characters_not_allowed".

StepValueValidator

`class StepValueValidator(limit_value, message=None)`

Raises a *ValidationError* with a code of 'step_size' if `value` is not an integral multiple of `limit_value`, which can be a float, integer or decimal value or a callable.

6.30 Built-in Views

Several of Django's built-in views are documented in [Writing views](#) as well as elsewhere in the documentation.

6.30.1 Serving files in development

`static.serve(request, path, document_root, show_indexes=False)`

There may be files other than your project's static assets that, for convenience, you'd like to have Django serve for you in local development. The *serve()* view can be used to serve any directory you give it. (This view is not hardened for production use and should be used only as a development aid; you should serve these files in production using a real front-end web server).

The most likely example is user-uploaded content in `MEDIA_ROOT`. `django.contrib.staticfiles` is intended for static assets and has no built-in handling for user-uploaded files, but you can have Django serve your `MEDIA_ROOT` by appending something like this to your URLconf:

```
from django.conf import settings
from django.urls import re_path
from django.views.static import serve

# ... the rest of your URLconf goes here ...

if settings.DEBUG:
    urlpatterns += [
        re_path(
            r"^media/(?P<path>.*)$",
            serve,
            {
                "document_root": settings.MEDIA_ROOT,
            },
        ),
    ]
```

Note, the snippet assumes your `MEDIA_URL` has a value of `'media/'`. This will call the `serve()` view, passing in the path from the URLconf and the (required) `document_root` parameter.

Since it can become a bit cumbersome to define this URL pattern, Django ships with a small URL helper function `static()` that takes as parameters the prefix such as `MEDIA_URL` and a dotted path to a view, such as `'django.views.static.serve'`. Any other function parameter will be transparently passed to the view.

6.30.2 Error views

Django comes with a few views by default for handling HTTP errors. To override these with your own custom views, see [Customizing error views](#).

The 404 (page not found) view

```
defaults.page_not_found(request, exception, template_name='404.html')
```

When you raise `Http404` from within a view, Django loads a special view devoted to handling 404 errors. By default, it's the view `django.views.defaults.page_not_found()`, which either produces a “Not Found” message or loads and renders the template `404.html` if you created it in your root template directory.

The default 404 view will pass two variables to the template: `request_path`, which is the URL that resulted in the error, and `exception`, which is a useful representation of the exception that triggered the view (e.g. containing any message passed to a specific `Http404` instance).

Three things to note about 404 views:

- The 404 view is also called if Django doesn't find a match after checking every regular expression in the `URLconf`.
- The 404 view is passed a `RequestContext` and will have access to variables supplied by your template context processors (e.g. `MEDIA_URL`).
- If `DEBUG` is set to `True` (in your settings module), then your 404 view will never be used, and your `URLconf` will be displayed instead, with some debug information.

The 500 (server error) view

```
defaults.server_error(request, template_name='500.html')
```

Similarly, Django executes special-case behavior in the case of runtime errors in view code. If a view results in an exception, Django will, by default, call the view `django.views.defaults.server_error`, which either produces a “Server Error” message or loads and renders the template `500.html` if you created it in your root template directory.

The default 500 view passes no variables to the `500.html` template and is rendered with an empty `Context` to lessen the chance of additional errors.

If `DEBUG` is set to `True` (in your settings module), then your 500 view will never be used, and the traceback will be displayed instead, with some debug information.

The 403 (HTTP Forbidden) view

```
defaults.permission_denied(request, exception, template_name='403.html')
```

In the same vein as the 404 and 500 views, Django has a view to handle 403 Forbidden errors. If a view results in a 403 exception then Django will, by default, call the view `django.views.defaults.permission_denied`.

This view loads and renders the template `403.html` in your root template directory, or if this file does not exist, instead serves the text “403 Forbidden”, as per [RFC 9110#section-15.5.4](#) (the HTTP 1.1 Specification). The template context contains `exception`, which is the string representation of the exception that triggered the view.

`django.views.defaults.permission_denied` is triggered by a `PermissionDenied` exception. To deny access in a view you can use code like this:

```
from django.core.exceptions import PermissionDenied

def edit(request, pk):
    if not request.user.is_staff:
```

(continues on next page)

(continued from previous page)

```
raise PermissionDenied
# ...
```

The 400 (bad request) view

```
defaults.bad_request(request, exception, template_name='400.html')
```

When a *SuspiciousOperation* is raised in Django, it may be handled by a component of Django (for example resetting the session data). If not specifically handled, Django will consider the current request a ‘bad request’ instead of a server error.

`django.views.defaults.bad_request`, is otherwise very similar to the `server_error` view, but returns with the status code 400 indicating that the error condition was the result of a client operation. By default, nothing related to the exception that triggered the view is passed to the template context, as the exception message might contain sensitive information like filesystem paths.

`bad_request` views are also only used when *DEBUG* is `False`.

META-DOCUMENTATION AND MISCELLANY

Documentation that we can't find a more organized place for. Like that drawer in your kitchen with the scissors, batteries, duct tape, and other junk.

7.1 API stability

Django is committed to API stability and forwards-compatibility. In a nutshell, this means that code you develop against a version of Django will continue to work with future releases. You may need to make minor changes when upgrading the version of Django your project uses: see the “Backwards incompatible changes” section of the [release note](#) for the version or versions to which you are upgrading.

At the same time as making API stability a very high priority, Django is also committed to continual improvement, along with aiming for “one way to do it” (eventually) in the APIs we provide. This means that when we discover clearly superior ways to do things, we will deprecate and eventually remove the old ways. Our aim is to provide a modern, dependable web framework of the highest quality that encourages best practices in all projects that use it. By using incremental improvements, we try to avoid both stagnation and large breaking upgrades.

7.1.1 What “stable” means

In this context, stable means:

- All the public APIs (everything in this documentation) will not be moved or renamed without providing backwards-compatible aliases.
- If new features are added to these APIs –which is quite possible– they will not break or change the meaning of existing methods. In other words, “stable” does not (necessarily) mean “complete.”
- If, for some reason, an API declared stable must be removed or replaced, it will be declared deprecated but will remain in the API for at least two feature releases. Warnings will be issued when the deprecated method is called.

See [Official releases](#) for more details on how Django’s version numbering scheme works, and how features will be deprecated.

- We’ll only break backwards compatibility of these APIs without a deprecation process if a bug or security hole makes it completely unavoidable.

7.1.2 Stable APIs

In general, everything covered in the documentation –with the exception of anything in the [internals area](#) is considered stable.

7.1.3 Exceptions

There are a few exceptions to this stability and backwards-compatibility promise.

Security fixes

If we become aware of a security problem –hopefully by someone following our [security reporting policy](#) – we’ll do everything necessary to fix it. This might mean breaking backwards compatibility; security trumps the compatibility guarantee.

APIs marked as internal

Certain APIs are explicitly marked as “internal” in a couple of ways:

- Some documentation refers to internals and mentions them as such. If the documentation says that something is internal, we reserve the right to change it.
- Functions, methods, and other objects prefixed by a leading underscore (`_`). This is the standard Python way of indicating that something is private; if any method starts with a single `_`, it’s an internal API.

7.2 Design philosophies

This document explains some of the fundamental philosophies Django’s developers have used in creating the framework. Its goal is to explain the past and guide the future.

7.2.1 Overall

Loose coupling

A fundamental goal of Django’s stack is [loose coupling and tight cohesion](#). The various layers of the framework shouldn’t “know” about each other unless absolutely necessary.

For example, the template system knows nothing about web requests, the database layer knows nothing about data display and the view system doesn’t care which template system a programmer uses.

Although Django comes with a full stack for convenience, the pieces of the stack are independent of another wherever possible.

Less code

Django apps should use as little code as possible; they should lack boilerplate. Django should take full advantage of Python’s dynamic capabilities, such as introspection.

Quick development

The point of a web framework in the 21st century is to make the tedious aspects of web development fast. Django should allow for incredibly quick web development.

Don’t repeat yourself (DRY)

Every distinct concept and/or piece of data should live in one, and only one, place. Redundancy is bad. Normalization is good.

The framework, within reason, should deduce as much as possible from as little as possible.

See also:

The [discussion of DRY on the Portland Pattern Repository](#)

Explicit is better than implicit

This is a core Python principle listed in [PEP 20](#), and it means Django shouldn’t do too much “magic.” Magic shouldn’t happen unless there’s a really good reason for it. Magic is worth using only if it creates a huge convenience unattainable in other ways, and it isn’t implemented in a way that confuses developers who are trying to learn how to use the feature.

Consistency

The framework should be consistent at all levels. Consistency applies to everything from low-level (the Python coding style used) to high-level (the “experience” of using Django).

7.2.2 Models

Explicit is better than implicit

Fields shouldn’t assume certain behaviors based solely on the name of the field. This requires too much knowledge of the system and is prone to errors. Instead, behaviors should be based on keyword arguments and, in some cases, on the type of the field.

Include all relevant domain logic

Models should encapsulate every aspect of an “object,” following Martin Fowler’s [Active Record](#) design pattern.

This is why both the data represented by a model and information about it (its human-readable name, options like default ordering, etc.) are defined in the model class; all the information needed to understand a given model should be stored in the model.

7.2.3 Database API

The core goals of the database API are:

SQL efficiency

It should execute SQL statements as few times as possible, and it should optimize statements internally.

This is why developers need to call `save()` explicitly, rather than the framework saving things behind the scenes silently.

This is also why the `select_related()` `QuerySet` method exists. It’s an optional performance booster for the common case of selecting “every related object.”

Terse, powerful syntax

The database API should allow rich, expressive statements in as little syntax as possible. It should not rely on importing other modules or helper objects.

Joins should be performed automatically, behind the scenes, when necessary.

Every object should be able to access every related object, systemwide. This access should work both ways.

Option to drop into raw SQL easily, when needed

The database API should realize it's a shortcut but not necessarily an end-all-be-all. The framework should make it easy to write custom SQL –entire statements, or just custom `WHERE` clauses as custom parameters to API calls.

7.2.4 URL design

Loose coupling

URLs in a Django app should not be coupled to the underlying Python code. Tying URLs to Python function names is a Bad And Ugly Thing.

Along these lines, the Django URL system should allow URLs for the same app to be different in different contexts. For example, one site may put stories at `/stories/`, while another may use `/news/`.

Infinite flexibility

URLs should be as flexible as possible. Any conceivable URL design should be allowed.

Encourage best practices

The framework should make it just as easy (or even easier) for a developer to design pretty URLs than ugly ones.

File extensions in web-page URLs should be avoided.

Vignette-style commas in URLs deserve severe punishment.

Definitive URLs

Technically, `foo.com/bar` and `foo.com/bar/` are two different URLs, and search-engine robots (and some web traffic-analyzing tools) would treat them as separate pages. Django should make an effort to “normalize” URLs so that search-engine robots don’t get confused.

This is the reasoning behind the `APPEND_SLASH` setting.

7.2.5 Template system

Separate logic from presentation

We see a template system as a tool that controls presentation and presentation-related logic –and that’s it. The template system shouldn’t support functionality that goes beyond this basic goal.

Discourage redundancy

The majority of dynamic websites use some sort of common sitewide design –a common header, footer, navigation bar, etc. The Django template system should make it easy to store those elements in a single place, eliminating duplicate code.

This is the philosophy behind `template inheritance`.

Be decoupled from HTML

The template system shouldn’t be designed so that it only outputs HTML. It should be equally good at generating other text-based formats, or just plain text.

XML should not be used for template languages

Using an XML engine to parse templates introduces a whole new world of human error in editing templates –and incurs an unacceptable level of overhead in template processing.

Assume designer competence

The template system shouldn’t be designed so that templates necessarily are displayed nicely in WYSIWYG editors such as Dreamweaver. That is too severe of a limitation and wouldn’t allow the syntax to be as nice as it is. Django expects template authors are comfortable editing HTML directly.

Treat whitespace obviously

The template system shouldn't do magic things with whitespace. If a template includes whitespace, the system should treat the whitespace as it treats text –just display it. Any whitespace that's not in a template tag should be displayed.

Don't invent a programming language

The goal is not to invent a programming language. The goal is to offer just enough programming-esque functionality, such as branching and looping, that is essential for making presentation-related decisions. The [Django Template Language \(DTL\)](#) aims to avoid advanced logic.

The Django template system recognizes that templates are most often written by designers, not programmers, and therefore should not assume Python knowledge.

Safety and security

The template system, out of the box, should forbid the inclusion of malicious code –such as commands that delete database records.

This is another reason the template system doesn't allow arbitrary Python code.

Extensibility

The template system should recognize that advanced template authors may want to extend its technology.

This is the philosophy behind custom template tags and filters.

7.2.6 Views

Simplicity

Writing a view should be as simple as writing a Python function. Developers shouldn't have to instantiate a class when a function will do.

Use request objects

Views should have access to a request object –an object that stores metadata about the current request. The object should be passed directly to a view function, rather than the view function having to access the request data from a global variable. This makes it light, clean and easy to test views by passing in “fake” request objects.

Loose coupling

A view shouldn't care about which template system the developer uses –or even whether a template system is used at all.

Differentiate between GET and POST

GET and POST are distinct; developers should explicitly use one or the other. The framework should make it easy to distinguish between GET and POST data.

7.2.7 Cache Framework

The core goals of Django's [cache framework](#) are:

Less code

A cache should be as fast as possible. Hence, all framework code surrounding the cache backend should be kept to the absolute minimum, especially for `get()` operations.

Consistency

The cache API should provide a consistent interface across the different cache backends.

Extensibility

The cache API should be extensible at the application level based on the developer's needs (for example, see [Cache key transformation](#)).

7.3 Third-party distributions of Django

Many third-party distributors are now providing versions of Django integrated with their package-management systems. These can make installation and upgrading much easier for users of Django since the integration includes the ability to automatically install dependencies (like database adapters) that Django requires.

Typically, these packages are based on the latest stable release of Django, so if you want to use the development version of Django you'll need to follow the instructions for [installing the development version](#) from our Git repository.

If you're using Linux or a Unix installation, such as OpenSolaris, check with your distributor to see if they already package Django. If you're using a Linux distro and don't know how to find out if a package is

available, then now is a good time to learn. The Django Wiki contains a list of [Third Party Distributions](#) to help you out.

7.3.1 For distributors

If you'd like to package Django for distribution, we'd be happy to help out! Please join the [django-developers](#) mailing list and introduce yourself.

We also encourage all distributors to subscribe to the [django-announce](#) mailing list, which is a (very) low-traffic list for announcing new releases of Django and important bugfixes.

GLOSSARY

concrete model

A non-abstract (*`abstract=False`*) model.

field

An attribute on a [model](#); a given field usually maps directly to a single database column.

See [Models](#).

generic view

A higher-order [view](#) function that provides an abstract/generic implementation of a common idiom or pattern found in view development.

See [Class-based views](#).

model

Models store your application’ s data.

See [Models](#).

MTV

“Model-template-view” ; a software pattern, similar in style to MVC, but a better description of the way Django does things.

See [the FAQ entry](#).

MVC

[Model-view-controller](#); a software pattern. Django [follows MVC to some extent](#).

project

A Python package –i.e. a directory of code –that contains all the settings for an instance of Django. This would include database configuration, Django-specific options and application-specific settings.

property

Also known as “managed attributes” , and a feature of Python since version 2.2. This is a neat way to implement attributes whose usage resembles attribute access, but whose implementation uses method calls.

See [property](#).

queryset

An object representing some set of rows to be fetched from the database.

See [Making queries](#).

slug

A short label for something, containing only letters, numbers, underscores or hyphens. They're generally used in URLs. For example, in a typical blog entry URL:

`https://www.djangoproject.com/weblog/2008/apr/12/spring/`

the last bit (`spring`) is the slug.

template

A chunk of text that acts as formatting for representing data. A template helps to abstract the presentation of data from the data itself.

See [Templates](#).

view

A function responsible for rendering a page.

RELEASE NOTES

Release notes for the official Django releases. Each release note will tell you what’s new in each version, and will also describe any backwards-incompatible changes made in that version.

For those [upgrading to a new version of Django](#), you will need to check all the backwards-incompatible changes and [deprecated features](#) for each ‘final’ release from the one after your current Django version, up to and including the new version.

9.1 Final releases

Below are release notes through Django 4.2 and its patch releases. Newer versions of the documentation contain the release notes for any later releases.

9.1.1 4.2 release

Django 4.2.4 release notes

Expected August 1, 2023

Django 4.2.4 fixes several bugs in 4.2.3.

Bugfixes

- ...

Django 4.2.3 release notes

July 3, 2023

Django 4.2.3 fixes a security issue with severity “moderate” and several bugs in 4.2.2.

CVE-2023-36053: Potential regular expression denial of service vulnerability in `EmailValidator/URLValidator`

`EmailValidator` and `URLValidator` were subject to potential regular expression denial of service attack via a very large number of domain name labels of emails and URLs.

Bugfixes

- Fixed a regression in Django 4.2 that caused incorrect alignment of timezone warnings for `DateField` and `TimeField` in the admin ([#34645](#)).
- Fixed a regression in Django 4.2 that caused incorrect highlighting of rows in the admin changelist view when `ModelAdmin.list_editable` contained a `BooleanField` ([#34638](#)).

Django 4.2.2 release notes

June 5, 2023

Django 4.2.2 fixes several bugs in 4.2.1.

Bugfixes

- Fixed a regression in Django 4.2 that caused an unnecessary `DBMS_LOB.SUBSTR()` wrapping in the `__isnull` and `__exact=None` lookups for `TextField()/BinaryField()` on Oracle ([#34544](#)).
- Restored, following a regression in Django 4.2, `get_prep_value()` call in `JSONField` subclasses ([#34539](#)).
- Fixed a regression in Django 4.2 that caused a crash of `QuerySet.defer()` when passing a `ManyToManyField` or `GenericForeignKey` reference. While doing so is a no-op, it was allowed in older version ([#34570](#)).
- Fixed a regression in Django 4.2 that caused a crash of `QuerySet.only()` when passing a reverse `OneToOneField` reference ([#34612](#)).
- Fixed a bug in Django 4.2 where `makemigrations --update` didn't respect the `--name` option ([#34568](#)).
- Fixed a performance regression in Django 4.2 when compiling queries without ordering ([#34580](#)).

- Fixed a regression in Django 4.2 where nonexistent stylesheet was linked on a “Congratulations!” page (#34588).
- Fixed a regression in Django 4.2 that caused a crash of `QuerySet.aggregate()` with expressions referencing other aggregates (#34551).
- Fixed a regression in Django 4.2 that caused a crash of `QuerySet.aggregate()` with aggregates referencing subqueries (#34551).
- Fixed a regression in Django 4.2 that caused a crash of queriesets on SQLite when filtering on `DecimalField` against values outside of the defined range (#34590).
- Fixed a regression in Django 4.2 that caused a serialization crash on a `ManyToManyField` without a natural key when its `Manager`’s base `QuerySet` used `select_related()` (#34620).

Django 4.2.1 release notes

May 3, 2023

Django 4.2.1 fixes a security issue with severity “low” and several bugs in 4.2.

CVE-2023-31047: Potential bypass of validation when uploading multiple files using one form field

Uploading multiple files using one form field has never been supported by `forms.FileField` or `forms.ImageField` as only the last uploaded file was validated. Unfortunately, [Uploading multiple files](#) topic suggested otherwise.

In order to avoid the vulnerability, `ClearableFileInput` and `FileInput` form widgets now raise `ValueError` when the `multiple` HTML attribute is set on them. To prevent the exception and keep the old behavior, set `allow_multiple_selected` to `True`.

For more details on using the new attribute and handling of multiple files through a single field, see [Uploading multiple files](#).

Bugfixes

- Fixed a regression in Django 4.2 that caused a crash of `QuerySet.defer()` when deferring fields by attribute names (#34458).
- Fixed a regression in Django 4.2 that caused a crash of `SearchVector` function with `%` characters (#34459).
- Fixed a regression in Django 4.2 that caused aggregation over query that uses explicit grouping to group against the wrong columns (#34464).
- Reallowed, following a regression in Django 4.2, setting the `"cursor_factory"` option in `OPTIONS` on PostgreSQL (#34466).

- Enforced UTF-8 client encoding on PostgreSQL, following a regression in Django 4.2 ([#34470](#)).
- Fixed a regression in Django 4.2 where `i18n_patterns()` didn't respect the `prefix_default_language` argument when a fallback language of the default language was used ([#34455](#)).
- Fixed a regression in Django 4.2 where translated URLs of the default language from `i18n_patterns()` with `prefix_default_language` set to `False` raised 404 errors for a request with a different language ([#34515](#)).
- Fixed a regression in Django 4.2 where creating copies and deep copies of `HttpRequest`, `HttpResponse`, and their subclasses didn't always work correctly ([#34482](#), [#34484](#)).
- Fixed a regression in Django 4.2 where `timesince` and `timeuntil` template filters returned incorrect results for a datetime with a non-UTC timezone when a time difference is less than 1 day ([#34483](#)).
- Fixed a regression in Django 4.2 that caused a crash of `SearchHeadline` function with `psycpg 3` ([#34486](#)).
- Fixed a regression in Django 4.2 that caused incorrect `ClearableFileInput` margins in the admin ([#34506](#)).
- Fixed a regression in Django 4.2 where breadcrumbs didn't appear on admin site app index views ([#34512](#)).
- Made squashing migrations reduce `AddIndex`, `RemoveIndex`, `RenameIndex`, and `CreateModel` operations which allows removing a deprecated `Meta.index_together` option from historical migrations and use `Meta.indexes` instead ([#34525](#)).

Django 4.2 release notes

April 3, 2023

Welcome to Django 4.2!

These release notes cover the [new features](#), as well as some [backwards incompatible changes](#) you'll want to be aware of when upgrading from Django 4.1 or earlier. We've begun the deprecation process for some [features](#).

See the [How to upgrade Django to a newer version](#) guide if you're updating an existing project.

Django 4.2 is designated as a [long-term support release](#). It will receive security updates for at least three years after its release. Support for the previous LTS, Django 3.2, will end in April 2024.

Python compatibility

Django 4.2 supports Python 3.8, 3.9, 3.10, and 3.11. We highly recommend and only officially support the latest release of each series.

What's new in Django 4.2

Psycopg 3 support

Django now supports [psycopg](#) version 3.1.8 or higher. To update your code, install the [psycopg library](#), you don't need to change the [ENGINE](#) as `django.db.backends.postgresql` supports both libraries.

Support for [psycopg2](#) is likely to be deprecated and removed at some point in the future.

Be aware that [psycopg 3](#) introduces some breaking changes over [psycopg2](#). As a consequence, you may need to make some changes to account for [differences from psycopg2](#).

Comments on columns and tables

The new `Field.db_comment` and `Meta.db_table_comment` options allow creating comments on columns and tables, respectively. For example:

```
from django.db import models

class Question(models.Model):
    text = models.TextField(db_comment="Poll question")
    pub_date = models.DateTimeField(
        db_comment="Date and time when the question was published",
    )

    class Meta:
        db_table_comment = "Poll questions"

class Answer(models.Model):
    question = models.ForeignKey(
        Question,
        on_delete=models.CASCADE,
        db_comment="Reference to a question",
    )
    answer = models.TextField(db_comment="Question answer")
```

(continues on next page)

(continued from previous page)

```
class Meta:
    db_table_comment = "Question answers"
```

Also, the new `AlterModelTableComment` operation allows changing table comments defined in the `Meta.db_table_comment`.

Mitigation for the BREACH attack

`GZipMiddleware` now includes a mitigation for the BREACH attack. It will add up to 100 random bytes to gzip responses to make BREACH attacks harder. Read more about the mitigation technique in the [Heal The Breach \(HTB\)](#) paper.

In-memory file storage

The new `django.core.files.storage.InMemoryStorage` class provides a non-persistent storage useful for speeding up tests by avoiding disk access.

Custom file storages

The new `STORAGES` setting allows configuring multiple custom file storage backends. It also controls storage engines for managing `files` (the "default" key) and `static files` (the "staticfiles" key).

The old `DEFAULT_FILE_STORAGE` and `STATICFILES_STORAGE` settings are deprecated as of this release.

Minor features

`django.contrib.admin`

- The light or dark color theme of the admin can now be toggled in the UI, as well as being set to follow the system setting.
- The admin's font stack now prefers system UI fonts and no longer requires downloading fonts. Additionally, CSS variables are available to more easily override the default font families.
- The `admin/delete_confirmation.html` template now has some additional blocks and scripting hooks to ease customization.
- The chosen options of `filter_horizontal` and `filter_vertical` widgets are now filterable.
- The `admin/base.html` template now has a new block `nav-breadcrumbs` which contains the navigation landmark and the `breadcrumbs` block.
- `ModelAdmin.list_editable` now uses atomic transactions when making edits.

- jQuery is upgraded from version 3.6.0 to 3.6.4.

`django.contrib.auth`

- The default iteration count for the PBKDF2 password hasher is increased from 390,000 to 600,000.
- *UserCreationForm* now saves many-to-many form fields for a custom user model.
- The new *BaseUserCreationForm* is now the recommended base class for customizing the user creation form.

`django.contrib.gis`

- The *GeoJSON* serializer now outputs the `id` key for serialized features, which defaults to the primary key of objects.
- The *GDALRaster* class now supports `pathlib.Path`.
- The *GeoIP2* class now supports `.mmdb` files downloaded from DB-IP.
- The OpenLayers template widget no longer includes inline CSS (which also removes the former `map_css` block) to better comply with a strict Content Security Policy.
- *OpenLayersWidget* is now based on OpenLayers 7.2.2 (previously 4.6.5).
- The new *isempty* lookup and *IsEmpty()* expression allow filtering empty geometries on PostGIS.
- The new *FromWKB()* and *FromWKT()* functions allow creating geometries from Well-known binary (WKB) and Well-known text (WKT) representations.

`django.contrib.postgres`

- The new *trigram_strict_word_similar* lookup, and the *TrigramStrictWordSimilarity()* and *TrigramStrictWordDistance()* expressions allow using trigram strict word similarity.
- The *arrayfield.overlap* lookup now supports `QuerySet.values()` and `values_list()` as a right-hand side.

`django.contrib.sitemaps`

- The new *Sitemap.get_languages_for_item()* method allows customizing the list of languages for which the item is displayed.

`django.contrib.staticfiles`

- *ManifestStaticFilesStorage* now has experimental support for replacing paths to JavaScript modules in `import` and `export` statements with their hashed counterparts. If you want to try it, subclass *ManifestStaticFilesStorage* and set the `support_js_module_import_aggregation` attribute to `True`.
- The new *ManifestStaticFilesStorage.manifest_hash* attribute provides a hash over all files in the manifest and changes whenever one of the files changes.

Database backends

- The new "assume_role" option is now supported in *OPTIONS* on PostgreSQL to allow specifying the session role.
- The new "server_side_binding" option is now supported in *OPTIONS* on PostgreSQL with `psycopg` 3.1.8+ to allow using server-side binding cursors.

Error Reporting

- The debug page now shows *exception notes* and *fine-grained error locations* on Python 3.11+.
- Session cookies are now treated as credentials and therefore hidden and replaced with stars (`*****`) in error reports.

Forms

- *ModelForm* now accepts the new `Meta` option `formfield_callback` to customize form fields.
- *modelform_factory()* now respects the `formfield_callback` attribute of the form's `Meta`.

Internationalization

- Added support and translations for the Central Kurdish (Sorani) language.

Logging

- The `django.db.backends` logger now logs transaction management queries (BEGIN, COMMIT, and ROLLBACK) at the DEBUG level.

Management Commands

- `makemessages` command now supports locales with private sub-tags such as `nl_NL-x-informal`.
- The new `makemigrations --update` option merges model changes into the latest migration and optimizes the resulting operations.

Migrations

- Migrations now support serialization of `enum.Flag` objects.

Models

- `QuerySet` now extensively supports filtering against [Window functions](#) with the exception of disjunctive filter lookups against window functions when performing aggregation.
- `prefetch_related()` now supports `Prefetch` objects with sliced querysets.
- Registering lookups on `Field` instances is now supported.
- The new `robust` argument for `on_commit()` allows performing actions that can fail after a database transaction is successfully committed.
- The new `KT()` expression represents the text value of a key, index, or path transform of `JSONField`.
- `Now` now supports microsecond precision on MySQL and millisecond precision on SQLite.
- `F()` expressions that output `BooleanField` can now be negated using `~F()` (inversion operator).
- `Model` now provides asynchronous versions of some methods that use the database, using an `a` prefix: `adelete()`, `arefresh_from_db()`, and `asave()`.
- Related managers now provide asynchronous versions of methods that change a set of related objects, using an `a` prefix: `aadd()`, `aclear()`, `aremove()`, and `aset()`.
- `CharField.max_length` is no longer required to be set on PostgreSQL, which supports unlimited VARCHAR columns.

Requests and Responses

- *StreamingHttpResponse* now supports async iterators when Django is served via ASGI.

Tests

- The `test --debug-sql` option now formats SQL queries with `sqlparse`.
- The *RequestFactory*, *AsyncRequestFactory*, *Client*, and *AsyncClient* classes now support the `headers` parameter, which accepts a dictionary of header names and values. This allows a more natural syntax for declaring headers.

```
# Before:
self.client.get("/home/", HTTP_ACCEPT_LANGUAGE="fr")
await self.async_client.get("/home/", ACCEPT_LANGUAGE="fr")

# After:
self.client.get("/home/", headers={"accept-language": "fr"})
await self.async_client.get("/home/", headers={"accept-language": "fr"})
```

Utilities

- The new encoder parameter for *django.utils.html.json_script()* function allows customizing a JSON encoder class.
- The private internal vendored copy of `urllib.parse.urlsplit()` now strips `'\r'`, `'\n'`, and `'\t'` (see [CVE-2022-0391](#) and [bpo-43882](#)). This is to protect projects that may be incorrectly using the internal `url_has_allowed_host_and_scheme()` function, instead of using one of the documented functions for handling URL redirects. The Django functions were not affected.
- The new *django.utils.http.content_disposition_header()* function returns a Content-Disposition HTTP header value as specified by [RFC 6266](#).

Validators

- The list of common passwords used by *CommonPasswordValidator* is updated to the most recent version.

Backwards incompatible changes in 4.2

Database backend API

This section describes changes that may be needed in third-party database backends.

- `DatabaseFeatures.allows_group_by_pk` is removed as it only remained to accommodate a MySQL extension that has been supplanted by proper functional dependency detection in MySQL 5.7.15. Note that `DatabaseFeatures.allows_group_by_selected_pks` is still supported and should be enabled if your backend supports functional dependency detection in `GROUP BY` clauses as specified by the SQL:1999 standard.
- `inspectdb` now uses `display_size` from `DatabaseIntrospection.get_table_description()` rather than `internal_size` for `CharField`.

Dropped support for MariaDB 10.3

Upstream support for MariaDB 10.3 ends in May 2023. Django 4.2 supports MariaDB 10.4 and higher.

Dropped support for MySQL 5.7

Upstream support for MySQL 5.7 ends in October 2023. Django 4.2 supports MySQL 8 and higher.

Dropped support for PostgreSQL 11

Upstream support for PostgreSQL 11 ends in November 2023. Django 4.2 supports PostgreSQL 12 and higher.

Setting `update_fields` in `Model.save()` may now be required

In order to avoid updating unnecessary columns, `QuerySet.update_or_create()` now passes `update_fields` to the `Model.save()` calls. As a consequence, any fields modified in the custom `save()` methods should be added to the `update_fields` keyword argument before calling `super()`. See [Overriding predefined model methods](#) for more details.

Miscellaneous

- The undocumented `django.http.multipartparser.parse_header()` function is removed. Use `django.utils.http.parse_header_parameters()` instead.
- `{% blocktranslate asvar ... %}` result is now marked as safe for (HTML) output purposes.
- The `autofocus` HTML attribute in the admin search box is removed as it can be confusing for screen readers.
- The `makemigrations --check` option no longer creates missing migration files.
- The `alias` argument for `Expression.get_group_by_cols()` is removed.
- The minimum supported version of `sqlparse` is increased from 0.2.2 to 0.3.1.
- The undocumented `negated` parameter of the `Exists` expression is removed.
- The `is_summary` argument of the undocumented `Query.add_annotation()` method is removed.
- The minimum supported version of `SQLite` is increased from 3.9.0 to 3.21.0.
- The minimum supported version of `asgiref` is increased from 3.5.2 to 3.6.0.
- `UserCreationForm` now rejects usernames that differ only in case. If you need the previous behavior, use `BaseUserCreationForm` instead.
- The minimum supported version of `mysqlclient` is increased from 1.4.0 to 1.4.3.
- The minimum supported version of `argon2-cffi` is increased from 19.1.0 to 19.2.0.
- The minimum supported version of `Pillow` is increased from 6.2.0 to 6.2.1.
- The minimum supported version of `jinja2` is increased from 2.9.2 to 2.11.0.
- The minimum supported version of `redis-py` is increased from 3.0.0 to 3.4.0.
- Manually instantiated `WSGIRequest` objects must be provided a file-like object for `wsgi.input`. Previously, Django was more lax than the expected behavior as specified by the WSGI specification.
- Support for `PROJ < 5` is removed.
- `EmailBackend` now verifies a `hostname` and `certificates`. If you need the previous behavior that is less restrictive and not recommended, subclass `EmailBackend` and override the `ssl_context` property.

Features deprecated in 4.2

`index_together` option is deprecated in favor of `indexes`

The `Meta.index_together` option is deprecated in favor of the `indexes` option.

Migrating existing `index_together` should be handled as a migration. For example:

```
class Author(models.Model):
    rank = models.IntegerField()
    name = models.CharField(max_length=30)

    class Meta:
        index_together = [["rank", "name"]]
```

Should become:

```
class Author(models.Model):
    rank = models.IntegerField()
    name = models.CharField(max_length=30)

    class Meta:
        indexes = [models.Index(fields=["rank", "name"])]
```

Running the `makemigrations` command will generate a migration containing a `RenameIndex` operation which will rename the existing index. Next, consider squashing migrations to remove `index_together` from historical migrations.

The `AlterIndexTogether` migration operation is now officially supported only for pre-Django 4.2 migration files. For backward compatibility reasons, it's still part of the public API, and there's no plan to deprecate or remove it, but it should not be used for new migrations. Use `AddIndex` and `RemoveIndex` operations instead.

Passing encoded JSON string literals to `JSONField` is deprecated

`JSONField` and its associated lookups and aggregates used to allow passing JSON encoded string literals which caused ambiguity on whether string literals were already encoded from database backend's perspective.

During the deprecation period string literals will be attempted to be JSON decoded and a warning will be emitted on success that points at passing non-encoded forms instead.

Code that use to pass JSON encoded string literals:

```
Document.objects.bulk_create(
    Document(data=Value("null")),
    Document(data=Value("[]")),
```

(continues on next page)

(continued from previous page)

```
Document(data=Value("foo-bar")),
)
Document.objects.annotate(
    JSONBAgg("field", default=Value("")),
)
```

Should become:

```
Document.objects.bulk_create(
    Document(data=Value(None, JSONField())),
    Document(data=[]),
    Document(data="foo-bar"),
)
Document.objects.annotate(
    JSONBAgg("field", default=[]),
)
```

From Django 5.1+ string literals will be implicitly interpreted as JSON string literals.

Miscellaneous

- The `BaseUserManager.make_random_password()` method is deprecated. See [recipes and best practices](#) for using Python's `secrets` module to generate passwords.
- The `length_is` template filter is deprecated in favor of `length` and the `==` operator within an `{% if %}` tag. For example

```
{% if value|length == 4 %}...{% endif %}
{% if value|length == 4 %}True{% else %}False{% endif %}
```

instead of:

```
{% if value|length_is:4 %}...{% endif %}
{{ value|length_is:4 }}
```

- `django.contrib.auth.hashers.SHA1PasswordHasher`, `django.contrib.auth.hashers.UnsaltedSHA1PasswordHasher`, and `django.contrib.auth.hashers.UnsaltedMD5PasswordHasher` are deprecated.
- `django.contrib.postgres.fields.CICharField` is deprecated in favor of `CharField(db_collation="...")` with a case-insensitive non-deterministic collation.
- `django.contrib.postgres.fields.CIEmailField` is deprecated in favor of `EmailField(db_collation="...")` with a case-insensitive non-deterministic collation.

- `django.contrib.postgres.fields.CITextField` is deprecated in favor of `TextField(db_collation="...")` with a case-insensitive non-deterministic collation.
- `django.contrib.postgres.fields.CIText` mixin is deprecated.
- The `map_height` and `map_width` attributes of `BaseGeometryWidget` are deprecated, use CSS to size map widgets instead.
- `SimpleTestCase.assertFormsetError()` is deprecated in favor of `assertFormSetError()`.
- `TransactionTestCase.assertQuerysetEqual()` is deprecated in favor of `assertQuerySetEqual()`.
- Passing positional arguments to `Signer` and `TimestampSigner` is deprecated in favor of keyword-only arguments.
- The `DEFAULT_FILE_STORAGE` setting is deprecated in favor of `STORAGES["default"]`.
- The `STATICFILES_STORAGE` setting is deprecated in favor of `STORAGES["staticfiles"]`.
- The `django.core.files.storage.get_storage_class()` function is deprecated.

9.1.2 4.1 release

Django 4.1.10 release notes

July 3, 2023

Django 4.1.10 fixes a security issue with severity “moderate” in 4.1.9.

CVE-2023-36053: Potential regular expression denial of service vulnerability in `EmailValidator/URLValidator`

`EmailValidator` and `URLValidator` were subject to potential regular expression denial of service attack via a very large number of domain name labels of emails and URLs.

Django 4.1.9 release notes

May 3, 2023

Django 4.1.9 fixes a security issue with severity “low” in 4.1.8.

CVE-2023-31047: Potential bypass of validation when uploading multiple files using one form field

Uploading multiple files using one form field has never been supported by `forms.FileField` or `forms.ImageField` as only the last uploaded file was validated. Unfortunately, [Uploading multiple files](#) topic suggested otherwise.

In order to avoid the vulnerability, `ClearableFileInput` and `FileInput` form widgets now raise `ValueError` when the `multiple` HTML attribute is set on them. To prevent the exception and keep the old behavior, set `allow_multiple_selected` to `True`.

For more details on using the new attribute and handling of multiple files through a single field, see [Uploading multiple files](#).

Django 4.1.8 release notes

April 5, 2023

Django 4.1.8 fixes a bug in 4.1.7.

Bugfixes

- Fixed a bug in Django 4.1 that caused invalidation of sessions when rotating secret keys with `SECRET_KEY_FALLBACKS` ([#34384](#)).

Django 4.1.7 release notes

February 14, 2023

Django 4.1.7 fixes a security issue with severity “moderate” and a bug in 4.1.6.

CVE-2023-24580: Potential denial-of-service vulnerability in file uploads

Passing certain inputs to multipart forms could result in too many open files or memory exhaustion, and provided a potential vector for a denial-of-service attack.

The number of files parts parsed is now limited via the new `DATA_UPLOAD_MAX_NUMBER_FILES` setting.

Bugfixes

- Fixed a bug in Django 4.1 that caused a crash of model validation on `ValidationError` with no code ([#34319](#)).

Django 4.1.6 release notes

February 1, 2023

Django 4.1.6 fixes a security issue with severity “moderate” and a bug in 4.1.5.

CVE-2023-23969: Potential denial-of-service via Accept-Language headers

The parsed values of `Accept-Language` headers are cached in order to avoid repetitive parsing. This leads to a potential denial-of-service vector via excessive memory usage if large header values are sent.

In order to avoid this vulnerability, the `Accept-Language` header is now parsed up to a maximum length.

Bugfixes

- Fixed a bug in Django 4.1 that caused a crash of model validation on `UniqueConstraint` with ordered expressions ([#34291](#)).

Django 4.1.5 release notes

January 2, 2023

Django 4.1.5 fixes a bug in 4.1.4. Also, the latest string translations from Transifex are incorporated.

Bugfixes

- Fixed a long standing bug in the `__len` lookup for `ArrayField` that caused a crash of model validation on `Meta.constraints` ([#34205](#)).

Django 4.1.4 release notes

December 6, 2022

Django 4.1.4 fixes several bugs in 4.1.3.

Bugfixes

- Fixed a regression in Django 4.1 that caused an unnecessary table rebuild when adding a `ManyToManyField` on SQLite (#34138).
- Fixed a bug in Django 4.1 that caused a crash of the sitemap index view with an empty `Sitemap.items()` and a callable `lastmod` (#34088).
- Fixed a bug in Django 4.1 that caused a crash using `acreate()`, `aget_or_create()`, and `aupdate_or_create()` asynchronous methods of related managers (#34139).
- Fixed a bug in Django 4.1 that caused a crash of `QuerySet.bulk_create()` with "pk" in `unique_fields` (#34177).
- Fixed a bug in Django 4.1 that caused a crash of `QuerySet.bulk_create()` on fields with `db_column` (#34171).

Django 4.1.3 release notes

November 1, 2022

Django 4.1.3 fixes a bug in 4.1.2 and adds compatibility with Python 3.11.

Bugfixes

- Fixed a bug in Django 4.1 that caused non-Python files created by `startproject` and `startapp` management commands from custom templates to be incorrectly formatted using the `black` command (#34085).

Django 4.1.2 release notes

October 4, 2022

Django 4.1.2 fixes a security issue with severity “medium” and several bugs in 4.1.1.

CVE-2022-41323: Potential denial-of-service vulnerability in internationalized URLs

Internationalized URLs were subject to potential denial of service attack via the locale parameter.

Bugfixes

- Fixed a regression in Django 4.1 that caused a migration crash on PostgreSQL when adding a model with `ExclusionConstraint` (#33982).
- Fixed a regression in Django 4.1 that caused aggregation over a queryset that contained an `Exists` annotation to crash due to too many selected columns (#33992).
- Fixed a bug in Django 4.1 that caused an incorrect validation of `CheckConstraint` on `NULL` values (#33996).
- Fixed a regression in Django 4.1 that caused a `QuerySet.values()/values_list()` crash on `ArrayAgg()` and `JSONBAgg()` (#34016).
- Fixed a bug in Django 4.1 that caused `ModelAdmin.autocomplete_fields` to be incorrectly selected after adding/changing related instances via popups (#34025).
- Fixed a regression in Django 4.1 where the app registry was not populated when running parallel tests with the `multiprocessing` start method `spawn` (#34010).
- Fixed a regression in Django 4.1 where the `--debug-mode` argument to `test` did not work when running parallel tests with the `multiprocessing` start method `spawn` (#34010).
- Fixed a regression in Django 4.1 that didn't alter a sequence type when altering type of pre-Django 4.1 serial columns on PostgreSQL (#34058).
- Fixed a regression in Django 4.1 that caused a crash for `View` subclasses with asynchronous handlers when handling non-allowed HTTP methods (#34062).
- Reverted caching related managers for `ForeignKey`, `ManyToManyField`, and `GenericRelation` that caused the incorrect refreshing of related objects (#33984).
- Relaxed the system check added in Django 4.1 for the same name used for multiple template tag modules to a warning (#32987).

Django 4.1.1 release notes

September 5, 2022

Django 4.1.1 fixes several bugs in 4.1.

Bugfixes

- Reallowed, following a regression in Django 4.1, using `GeoIP2()` when GEOS is not installed ([#33886](#)).
- Fixed a regression in Django 4.1 that caused a crash of admin’s autocomplete widgets when translations are deactivated ([#33888](#)).
- Fixed a regression in Django 4.1 that caused a crash of the `test` management command when running in parallel and `multiprocessing` start method is `spawn` ([#33891](#)).
- Fixed a regression in Django 4.1 that caused an incorrect redirection to the admin changelist view when using “Save and continue editing” and “Save and add another” options ([#33893](#)).
- Fixed a regression in Django 4.1 that caused a crash of *Window* expressions with *ArrayAgg* ([#33898](#)).
- Fixed a regression in Django 4.1 that caused a migration crash on SQLite 3.35.5+ when removing an indexed field ([#33899](#)).
- Fixed a bug in Django 4.1 that caused a crash of model validation on `UniqueConstraint()` with field names in expressions ([#33902](#)).
- Fixed a bug in Django 4.1 that caused an incorrect validation of `CheckConstraint()` with range fields on PostgreSQL ([#33905](#)).
- Fixed a regression in Django 4.1 that caused an incorrect migration when adding `AutoField`, `BigAutoField`, or `SmallAutoField` on PostgreSQL ([#33919](#)).
- Fixed a regression in Django 4.1 that caused a migration crash on PostgreSQL when altering `AutoField`, `BigAutoField`, or `SmallAutoField` to `OneToOneField` ([#33932](#)).
- Fixed a migration crash on `ManyToManyField` fields with `through` referencing models in different apps ([#33938](#)).
- Fixed a regression in Django 4.1 that caused an incorrect migration when renaming a model with `ManyToManyField` and `db_table` ([#33953](#)).
- Reallowed, following a regression in Django 4.1, creating reverse foreign key managers on unsaved instances ([#33952](#)).
- Fixed a regression in Django 4.1 that caused a migration crash on SQLite < 3.20 ([#33960](#)).
- Fixed a regression in Django 4.1 that caused an admin crash when the *admindocs* app was used ([#33955](#), [#33971](#)).

Django 4.1 release notes

August 3, 2022

Welcome to Django 4.1!

These release notes cover the [new features](#), as well as some [backwards incompatible changes](#) you'll want to be aware of when upgrading from Django 4.0 or earlier. We've begun [the deprecation process](#) for some features.

See the [How to upgrade Django to a newer version](#) guide if you're updating an existing project.

Python compatibility

Django 4.1 supports Python 3.8, 3.9, 3.10, and 3.11 (as of 4.1.3). We highly recommend and only officially support the latest release of each series.

What's new in Django 4.1

Asynchronous handlers for class-based views

View subclasses may now define async HTTP method handlers:

```
import asyncio
from django.http import HttpResponse
from django.views import View

class AsyncView(View):
    async def get(self, request, *args, **kwargs):
        # Perform view logic using await.
        await asyncio.sleep(1)
        return HttpResponse("Hello async world!")
```

See [Asynchronous class-based views](#) for more details.

Asynchronous ORM interface

QuerySet now provides an asynchronous interface for all data access operations. These are named as-per the existing synchronous operations but with an `a` prefix, for example `acreate()`, `aget()`, and so on.

The new interface allows you to write asynchronous code without needing to wrap ORM operations in `sync_to_async()`:

```
async for author in Author.objects.filter(name__startswith="A"):
    book = await author.books.afirst()
```

Note that, at this stage, the underlying database operations remain synchronous, with contributions ongoing to push asynchronous support down into the SQL compiler, and integrate asynchronous database drivers. The new asynchronous queryset interface currently encapsulates the necessary `sync_to_async()` operations for you, and will allow your code to take advantage of developments in the ORM's asynchronous support as it evolves.

See [Asynchronous queries](#) for details and limitations.

Validation of Constraints

Check, *unique*, and *exclusion* constraints defined in the *Meta.constraints* option are now checked during model validation.

Form rendering accessibility

In order to aid users with screen readers, and other assistive technology, new `<div>` based form templates are available from this release. These provide more accessible navigation than the older templates, and are able to correctly group related controls, such as radio-lists, into fieldsets.

The new templates are recommended, and will become the default form rendering style when outputting a form, like `{% form %}` in a template, from Django 5.0.

In order to ease adopting the new output style, the default form and formset templates are now configurable at the project level via the *FORM_RENDERER* setting.

See [the Forms section \(below\)](#) for full details.

CSRF_COOKIE_MASKED setting

The new *CSRF_COOKIE_MASKED* transitional setting allows specifying whether to mask the CSRF cookie.

CsrfViewMiddleware no longer masks the CSRF cookie like it does the CSRF token in the DOM. If you are upgrading multiple instances of the same project to Django 4.1, you should set *CSRF_COOKIE_MASKED* to `True` during the transition, in order to allow compatibility with the older versions of Django. Once the transition to 4.1 is complete you can stop overriding *CSRF_COOKIE_MASKED*.

This setting is deprecated as of this release and will be removed in Django 5.0.

Minor features

`django.contrib.admin`

- The admin [dark mode CSS variables](#) are now applied in a separate stylesheet and template block.
- [ModelAdmin List Filters](#) providing custom `FieldListFilter` subclasses can now control the query string value separator when filtering for multiple values using the `__in` lookup.
- The admin *history view* is now paginated.
- Related widget wrappers now have a link to object's change form.
- The `AdminSite.get_app_list()` method now allows changing the order of apps and models on the admin index page.

`django.contrib.auth`

- The default iteration count for the PBKDF2 password hasher is increased from 320,000 to 390,000.
- The `RemoteUserBackend.configure_user()` method now allows synchronizing user attributes with attributes in a remote system such as an LDAP directory.

`django.contrib.gis`

- The new `GEOSGeometry.make_valid()` method allows converting invalid geometries to valid ones.
- The new `clone` argument for `GEOSGeometry.normalize()` allows creating a normalized clone of the geometry.

`django.contrib.postgres`

- The new `BitXor()` aggregate function returns an `int` of the bitwise XOR of all non-null input values.
- `SpGistIndex` now supports covering indexes on PostgreSQL 14+.
- `ExclusionConstraint` now supports covering exclusion constraints using SP-GiST indexes on PostgreSQL 14+.
- The new `default_bounds` attribute of `DateTimeRangeField` and `DecimalRangeField` allows specifying bounds for list and tuple inputs.
- `ExclusionConstraint` now allows specifying operator classes with the `OpClass()` expression.

`django.contrib.sitemaps`

- The default sitemap index template `<sitemapindex>` now includes the `<lastmod>` timestamp where available, through the new `get_latest_lastmod()` method. Custom sitemap index templates should be updated for the adjusted context variables.

`django.contrib.staticfiles`

- *ManifestStaticFilesStorage* now replaces paths to CSS source map references with their hashed counterparts.

Database backends

- Third-party database backends can now specify the minimum required version of the database using the `DatabaseFeatures.minimum_database_version` attribute which is a tuple (e.g. `(10, 0)` means “10.0”). If a minimum version is specified, backends must also implement `DatabaseWrapper.get_database_version()`, which returns a tuple of the current database version. The backend’s `DatabaseWrapper.init_connection_state()` method must call `super()` in order for the check to run.

Forms

- The default template used to render forms when cast to a string, e.g. in templates as `{{ form }}`, is now configurable at the project-level by setting `form_template_name` on the class provided for *FORM_RENDERER*.

`Form.template_name` is now a property deferring to the renderer, but may be overridden with a string value to specify the template name per-form class.

Similarly, the default template used to render formsets can be specified via the matching `formset_template_name` renderer attribute.

- The new `div.html` form template, referencing `Form.template_name_div` attribute, and matching `Form.as_div()` method, render forms using HTML `<div>` elements.

This new output style is recommended over the existing `as_table()`, `as_p()` and `as_ul()` styles, as the template implements `<fieldset>` and `<legend>` to group related inputs and is easier for screen reader users to navigate.

The div-based output will become the default rendering style from Django 5.0.

- In order to smooth adoption of the new `<div>` output style, two transitional form renderer classes are available: `django.forms.renderers.DjangoDivFormRenderer` and `django.forms.renderers.Jinja2DivFormRenderer`, for the Django and Jinja2 template backends respectively.

You can apply one of these via the *FORM_RENDERER* setting. For example:

```
FORM_RENDERER = "django.forms.renderers.DjangoDivFormRenderer"
```

Once the `<div>` output style is the default, from Django 5.0, these transitional renderers will be deprecated, for removal in Django 6.0. The `FORM_RENDERER` declaration can be removed at that time.

- If the new `<div>` output style is not appropriate for your project, you should define a renderer subclass specifying `form_template_name` and `formset_template_name` for your required style, and set `FORM_RENDERER` accordingly.

For example, for the `<p>` output style used by `as_p()`, you would define a form renderer setting `form_template_name` to `"django/forms/p.html"` and `formset_template_name` to `"django/forms/formsets/p.html"`.

- The new `legend_tag()` allows rendering field labels in `<legend>` tags via the new `tag` argument of `label_tag()`.
- The new `edit_only` argument for `modelformset_factory()` and `inlineformset_factory()` allows preventing new objects creation.
- The `js` and `css` class attributes of `Media` now allow using hashable objects, not only path strings, as long as those objects implement the `__html__()` method (typically when decorated with the `html_safe()` decorator).
- The new `BoundField.use_fieldset` and `Widget.use_fieldset` attributes help to identify widgets where its inputs should be grouped in a `<fieldset>` with a `<legend>`.
- The `error_messages` argument for `BaseFormSet` now allows customizing error messages for invalid number of forms by passing `'too_few_forms'` and `'too_many_forms'` keys.
- `IntegerField`, `FloatField`, and `DecimalField` now optionally accept a `step_size` argument. This is used to set the `step` HTML attribute, and is validated on form submission.

Internationalization

- The `i18n_patterns()` function now supports languages with both scripts and regions.

Management Commands

- `makemigrations --no-input` now logs default answers and reasons why migrations cannot be created.
- The new `makemigrations --scriptable` option diverts log output and input prompts to `stderr`, writing only paths of generated migration files to `stdout`.
- The new `migrate --prune` option allows deleting nonexistent migrations from the `django_migrations` table.

- Python files created by `startproject`, `startapp`, `optimizemigration`, `makemigrations`, and `squashmigrations` are now formatted using the `black` command if it is present on your `PATH`.
- The new `optimizemigration` command allows optimizing operations for a migration.

Migrations

- The new `RenameIndex` operation allows renaming indexes defined in the `Meta.indexes` or `index_together` options.
- The migrations autodetector now generates `RenameIndex` operations instead of `RemoveIndex` and `AddIndex`, when renaming indexes defined in the `Meta.indexes`.
- The migrations autodetector now generates `RenameIndex` operations instead of `AlterIndexTogether` and `AddIndex`, when moving indexes defined in the `Meta.index_together` to the `Meta.indexes`.

Models

- The `order_by` argument of the `Window` expression now accepts string references to fields and transforms.
- The new `CONN_HEALTH_CHECKS` setting allows enabling health checks for persistent database connections in order to reduce the number of failed requests, e.g. after database server restart.
- `QuerySet.bulk_create()` now supports updating fields when a row insertion fails uniqueness constraints. This is supported on MariaDB, MySQL, PostgreSQL, and SQLite 3.24+.
- `QuerySet.iterator()` now supports prefetching related objects as long as the `chunk_size` argument is provided. In older versions, no prefetching was done.
- `Q` objects and queriesets can now be combined using `^` as the exclusive or (XOR) operator. XOR is natively supported on MariaDB and MySQL. For databases that do not support XOR, the query will be converted to an equivalent using AND, OR, and NOT.
- The new `Field.non_db_attrs` attribute allows customizing attributes of fields that don't affect a column definition.
- On PostgreSQL, `AutoField`, `BigAutoField`, and `SmallAutoField` are now created as identity columns rather than serial columns with sequences.

Requests and Responses

- `HttpResponse.set_cookie()` now supports `timedelta` objects for the `max_age` argument.

Security

- The new `SECRET_KEY_FALLBACKS` setting allows providing a list of values for secret key rotation.
- The `SECURE_PROXY_SSL_HEADER` setting now supports a comma-separated list of protocols in the header value.

Signals

- The `pre_delete` and `post_delete` signals now dispatch the origin of the deletion.

Templates

- The HTML `<script>` element `id` attribute is no longer required when wrapping the `json_script` template filter.
- The `cached template loader` is now enabled in development, when `DEBUG` is `True`, and `OPTIONS['loaders']` isn't specified. You may specify `OPTIONS['loaders']` to override this, if necessary.

Tests

- The `DiscoverRunner` now supports running tests in parallel on macOS, Windows, and any other systems where the default `multiprocessing` start method is `spawn`.
- A nested atomic block marked as durable in `django.test.TestCase` now raises a `RuntimeError`, the same as outside of tests.
- `SimpleTestCase.assertFormError()` and `assertFormsetError()` now support passing a form/formset object directly.

URLs

- The new `ResolverMatch.captured_kwargs` attribute stores the captured keyword arguments, as parsed from the URL.
- The new `ResolverMatch.extra_kwargs` attribute stores the additional keyword arguments passed to the view function.

Utilities

- `SimpleLazyObject` now supports addition operations.
- `mark_safe()` now preserves lazy objects.

Validators

- The new `StepValueValidator` checks if a value is an integral multiple of a given step size. This new validator is used for the new `step_size` argument added to form fields representing numeric values.

Backwards incompatible changes in 4.1

Database backend API

This section describes changes that may be needed in third-party database backends.

- `BaseDatabaseFeatures.has_case_insensitive_like` is changed from `True` to `False` to reflect the behavior of most databases.
- `DatabaseIntrospection.get_key_columns()` is removed. Use `DatabaseIntrospection.get_relations()` instead.
- `DatabaseOperations.ignore_conflicts_suffix_sql()` method is replaced by `DatabaseOperations.on_conflict_suffix_sql()` that accepts the `fields`, `on_conflict`, `update_fields`, and `unique_fields` arguments.
- The `ignore_conflicts` argument of the `DatabaseOperations.insert_statement()` method is replaced by `on_conflict` that accepts `django.db.models.constants.OnConflict`.
- `DatabaseOperations._convert_field_to_tz()` is replaced by `DatabaseOperations._convert_sql_to_tz()` that accepts the `sql`, `params`, and `tzname` arguments.
- Several date and time methods on `DatabaseOperations` now take `sql` and `params` arguments instead of `field_name` and return 2-tuple containing some SQL and the parameters to be interpolated into that SQL. The changed methods have these new signatures:
 - `DatabaseOperations.date_extract_sql(lookup_type, sql, params)`

- `DatabaseOperations.datetime_extract_sql(lookup_type, sql, params, tzname)`
- `DatabaseOperations.time_extract_sql(lookup_type, sql, params)`
- `DatabaseOperations.date_trunc_sql(lookup_type, sql, params, tzname=None)`
- `DatabaseOperations.datetime_trunc_sql(self, lookup_type, sql, params, tzname)`
- `DatabaseOperations.time_trunc_sql(lookup_type, sql, params, tzname=None)`
- `DatabaseOperations.datetime_cast_date_sql(sql, params, tzname)`
- `DatabaseOperations.datetime_cast_time_sql(sql, params, tzname)`

`django.contrib.gis`

- Support for GDAL 2.1 is removed.
- Support for PostGIS 2.4 is removed.

Dropped support for PostgreSQL 10

Upstream support for PostgreSQL 10 ends in November 2022. Django 4.1 supports PostgreSQL 11 and higher.

Dropped support for MariaDB 10.2

Upstream support for MariaDB 10.2 ends in May 2022. Django 4.1 supports MariaDB 10.3 and higher.

Admin changelist searches spanning multi-valued relationships changes

Admin changelist searches using multiple search terms are now applied in a single call to `filter()`, rather than in sequential `filter()` calls.

For multi-valued relationships, this means that rows from the related model must match all terms rather than any term. For example, if `search_fields` is set to `['child__name', 'child__age']`, and a user searches for `'Jamal 17'`, parent rows will be returned only if there is a relationship to some 17-year-old child named Jamal, rather than also returning parents who merely have a younger or older child named Jamal in addition to some other 17-year-old.

See the [Spanning multi-valued relationships](#) topic for more discussion of this difference. In Django 4.0 and earlier, `get_search_results()` followed the second example query, but this undocumented behavior led to queries with excessive joins.

Reverse foreign key changes for unsaved model instances

In order to unify the behavior with many-to-many relations for unsaved model instances, a reverse foreign key now raises `ValueError` when calling *related managers* for unsaved objects.

Miscellaneous

- Related managers for *ForeignKey*, *ManyToManyField*, and *GenericRelation* are now cached on the *Model* instance to which they belong. This change was reverted in Django 4.1.2.
- The Django test runner now returns a non-zero error code for unexpected successes from tests marked with `unittest.expectedFailure()`.
- *CsrfViewMiddleware* no longer masks the CSRF cookie like it does the CSRF token in the DOM.
- *CsrfViewMiddleware* now uses `request.META['CSRF_COOKIE']` for storing the unmasked CSRF secret rather than a masked version. This is an undocumented, private API.
- The *ModelAdmin.actions* and *inlines* attributes now default to an empty tuple rather than an empty list to discourage unintended mutation.
- The `type="text/css"` attribute is no longer included in `<link>` tags for CSS *form media*.
- `formset:added` and `formset:removed` JavaScript events are now pure JavaScript events and don't depend on jQuery. See *Inline form events* for more details on the change.
- The `exc_info` argument of the undocumented `django.utils.log.log_response()` function is replaced by `exception`.
- The `size` argument of the undocumented `django.views.static.was_modified_since()` function is removed.
- The admin log out UI now uses POST requests.
- The undocumented `InlineAdminFormSet.non_form_errors` property is replaced by the `non_form_errors()` method. This is consistent with `BaseFormSet`.
- As per *above*, the cached template loader is now enabled in development. You may specify `OPTIONS['loaders']` to override this, if necessary.
- The undocumented `django.contrib.auth.views.SuccessURLAllowedHostsMixin` mixin is replaced by `RedirectURLMixin`.
- *BaseConstraint* subclasses must implement *validate()* method to allow those constraints to be used for validation.
- The undocumented `URLResolver._is_callback()`, `URLResolver._callback_strs`, and `URLPattern.lookup_str()` are moved to `django.contrib.admindocs.utils`.

- The `Model.full_clean()` method now converts an `exclude` value to a `set`. It's also preferable to pass an `exclude` value as a `set` to the `Model.clean_fields()`, `Model.full_clean()`, `Model.validate_unique()`, and `Model.validate_constraints()` methods.
- The minimum supported version of `asgiref` is increased from 3.4.1 to 3.5.2.
- Combined expressions no longer use the error-prone behavior of guessing `output_field` when argument types match. As a consequence, resolving an `output_field` for database functions and combined expressions may now crash with mixed types. You will need to explicitly set the `output_field` in such cases.
- The `makemessages` command no longer changes `.po` files when up to date. In older versions, `POT-Create-Date` was always updated.

Features deprecated in 4.1

Log out via GET

Logging out via GET requests to the *built-in `logout` view* is deprecated. Use POST requests instead.

If you want to retain the user experience of an HTML link, you can use a form that is styled to appear as a link:

```
<form id="logout-form" method="post" action="{% url 'admin:logout' %}">
  {% csrf_token %}
  <button type="submit">{% translate "Log out" %}</button>
</form>
```

```
#logout-form {
    display: inline;
}
#logout-form button {
    background: none;
    border: none;
    cursor: pointer;
    padding: 0;
    text-decoration: underline;
}
```

Miscellaneous

- The context for sitemap index templates of a flat list of URLs is deprecated. Custom sitemap index templates should be updated for the adjusted `context variables`, expecting a list of objects with `location` and optional `lastmod` attributes.
- `CSRF_COOKIE_MASKED` transitional setting is deprecated.
- The `name` argument of `django.utils.functional.cached_property()` is deprecated as it's unnecessary as of Python 3.6.
- The `opclasses` argument of `django.contrib.postgres.constraints.ExclusionConstraint` is deprecated in favor of using `OpClass()` in `ExclusionConstraint.expressions`. To use it, you need to add `'django.contrib.postgres'` in your `INSTALLED_APPS`.

After making this change, `makemigrations` will generate a new migration with two operations: `RemoveConstraint` and `AddConstraint`. Since this change has no effect on the database schema, the `SeparateDatabaseAndState` operation can be used to only update the migration state without running any SQL. Move the generated operations into the `state_operations` argument of `SeparateDatabaseAndState`. For example:

```
class Migration(migrations.Migration):
    ...

    operations = [
        migrations.SeparateDatabaseAndState(
            database_operations=[],
            state_operations=[
                migrations.RemoveConstraint(...),
                migrations.AddConstraint(...),
            ],
        ),
    ]
```

- The undocumented ability to pass `errors=None` to `SimpleTestCase.assertFormError()` and `assertFormsetError()` is deprecated. Use `errors=[]` instead.
- `django.contrib.sessions.serializers.PickleSerializer` is deprecated due to the risk of remote code execution.
- The usage of `QuerySet.iterator()` on a queryset that prefetches related objects without providing the `chunk_size` argument is deprecated. In older versions, no prefetching was done. Providing a value for `chunk_size` signifies that the additional query per chunk needed to prefetch is desired.
- Passing unsaved model instances to related filters is deprecated. In Django 5.0, the exception will be raised.

- `created=True` is added to the signature of `RemoteUserBackend.configure_user()`. Support for `RemoteUserBackend` subclasses that do not accept this argument is deprecated.
- The `django.utils.timezone.utc` alias to `datetime.timezone.utc` is deprecated. Use `datetime.timezone.utc` directly.
- Passing a response object and a form/formset name to `SimpleTestCase.assertFormError()` and `assertFormsetError()` is deprecated. Use:

```
assertFormError(response.context["form_name"], ...)
assertFormsetError(response.context["formset_name"], ...)
```

or pass the form/formset object directly instead.

- The undocumented `django.contrib.gis.admin.OpenLayersWidget` is deprecated.
- `django.contrib.auth.hashers.CryptPasswordHasher` is deprecated.
- The ability to pass `nulls_first=False` or `nulls_last=False` to `Expression.asc()` and `Expression.desc()` methods, and the `OrderBy` expression is deprecated. Use `None` instead.
- The `"django/forms/default.html"` and `"django/forms/formsets/default.html"` templates which are a proxy to the table-based templates are deprecated. Use the specific template instead.
- The undocumented `LogoutView.get_next_page()` method is renamed to `get_success_url()`.

Features removed in 4.1

These features have reached the end of their deprecation cycle and are removed in Django 4.1.

See [Features deprecated in 3.2](#) for details on these changes, including how to remove usage of these features.

- Support for assigning objects which don't support creating deep copies with `copy.deepcopy()` to class attributes in `TestCase.setUpTestData()` is removed.
- Support for using a boolean value in `BaseCommand.requires_system_checks` is removed.
- The `whitelist` argument and `domain_whitelist` attribute of `django.core.validators.EmailValidator` are removed.
- The `default_app_config` application configuration variable is removed.
- `TransactionTestCase.assertQuerysetEqual()` no longer calls `repr()` on a queryset when compared to string values.
- The `django.core.cache.backends.memcached.MemcachedCache` backend is removed.
- Support for the pre-Django 3.2 format of messages used by `django.contrib.messages.storage.cookie.CookieStorage` is removed.

9.1.3 4.0 release

Django 4.0.10 release notes

February 14, 2023

Django 4.0.10 fixes a security issue with severity “moderate” in 4.0.9.

CVE-2023-24580: Potential denial-of-service vulnerability in file uploads

Passing certain inputs to multipart forms could result in too many open files or memory exhaustion, and provided a potential vector for a denial-of-service attack.

The number of files parts parsed is now limited via the new `DATA_UPLOAD_MAX_NUMBER_FILES` setting.

Django 4.0.9 release notes

February 1, 2023

Django 4.0.9 fixes a security issue with severity “moderate” in 4.0.8.

CVE-2023-23969: Potential denial-of-service via Accept-Language headers

The parsed values of `Accept-Language` headers are cached in order to avoid repetitive parsing. This leads to a potential denial-of-service vector via excessive memory usage if large header values are sent.

In order to avoid this vulnerability, the `Accept-Language` header is now parsed up to a maximum length.

Django 4.0.8 release notes

October 4, 2022

Django 4.0.8 fixes a security issue with severity “medium” in 4.0.7.

CVE-2022-41323: Potential denial-of-service vulnerability in internationalized URLs

Internationalized URLs were subject to potential denial of service attack via the locale parameter.

Django 4.0.7 release notes

August 3, 2022

Django 4.0.7 fixes a security issue with severity “high” in 4.0.6.

CVE-2022-36359: Potential reflected file download vulnerability in `FileResponse`

An application may have been vulnerable to a reflected file download (RFD) attack that sets the Content-Disposition header of a *FileResponse* when the `filename` was derived from user-supplied input. The `filename` is now escaped to avoid this possibility.

Django 4.0.6 release notes

July 4, 2022

Django 4.0.6 fixes a security issue with severity “high” in 4.0.5.

CVE-2022-34265: Potential SQL injection via `Trunc(kind)` and `Extract(lookup_name)` arguments

Trunc() and *Extract()* database functions were subject to SQL injection if untrusted data was used as a `kind/lookup_name` value.

Applications that constrain the lookup name and kind choice to a known safe list are unaffected.

Django 4.0.5 release notes

June 1, 2022

Django 4.0.5 fixes several bugs in 4.0.4.

Bugfixes

- Fixed a bug in Django 4.0 where not all *OPTIONS* were passed to a Redis client (#33681).
- Fixed a bug in Django 4.0 that caused a crash of `QuerySet.filter()` on `IsNull()` expressions (#33705).
- Fixed a bug in Django 4.0 where a hidden quick filter toolbar in the admin’s navigation sidebar was focusable (#33725).

Django 4.0.4 release notes

April 11, 2022

Django 4.0.4 fixes two security issues with severity “high” and two bugs in 4.0.3.

CVE-2022-28346: Potential SQL injection in `QuerySet.annotate()`, `aggregate()`, and `extra()`

`QuerySet.annotate()`, `aggregate()`, and `extra()` methods were subject to SQL injection in column aliases, using a suitably crafted dictionary, with dictionary expansion, as the `**kwargs` passed to these methods.

CVE-2022-28347: Potential SQL injection via `QuerySet.explain(**options)` on PostgreSQL

`QuerySet.explain()` method was subject to SQL injection in option names, using a suitably crafted dictionary, with dictionary expansion, as the `**options` argument.

Bugfixes

- Fixed a regression in Django 4.0 that caused ignoring multiple `FilteredRelation()` relationships to the same field (#33598).
- Fixed a regression in Django 3.2.4 that caused the auto-reloader to no longer detect changes when the `DIRS` option of the `TEMPLATES` setting contained an empty string (#33628).

Django 4.0.3 release notes

March 1, 2022

Django 4.0.3 fixes several bugs in 4.0.2. Also, all Python code in Django is reformatted with `black`.

Bugfixes

- Prevented, following a regression in Django 4.0.1, `makemigrations` from generating infinite migrations for a model with `ManyToManyField` to a lowercased swappable model such as `'auth.user'` (#33515).
- Fixed a regression in Django 4.0 that caused a crash when rendering invalid inlines with `readonly_fields` in the admin (#33547).

Django 4.0.2 release notes

February 1, 2022

Django 4.0.2 fixes two security issues with severity “medium” and several bugs in 4.0.1. Also, the latest string translations from Transifex are incorporated, with a special mention for Bulgarian (fully translated).

CVE-2022-22818: Possible XSS via `{% debug %}` template tag

The `{% debug %}` template tag didn’t properly encode the current context, posing an XSS attack vector.

In order to avoid this vulnerability, `{% debug %}` no longer outputs information when the `DEBUG` setting is `False`, and it ensures all context variables are correctly escaped when the `DEBUG` setting is `True`.

CVE-2022-23833: Denial-of-service possibility in file uploads

Passing certain inputs to multipart forms could result in an infinite loop when parsing files.

Bugfixes

- Fixed a bug in Django 4.0 where `TestCase.captureOnCommitCallbacks()` could execute callbacks multiple times (#33410).
- Fixed a regression in Django 4.0 where `help_text` was HTML-escaped in automatically-generated forms (#33419).
- Fixed a regression in Django 4.0 that caused displaying an incorrect name for class-based views on the technical 404 debug page (#33425).
- Fixed a regression in Django 4.0 that caused an incorrect `repr` of `ResolverMatch` for class-based views (#33426).
- Fixed a regression in Django 4.0 that caused a crash of `makemigrations` on models without `Meta.order_with_respect_to` but with a field named `_order` (#33449).
- Fixed a regression in Django 4.0 that caused incorrect `ModelAdmin.radio_fields` layout in the admin (#33407).
- Fixed a duplicate operation regression in Django 4.0 that caused a migration crash when altering a primary key type for a concrete parent model referenced by a foreign key (#33462).
- Fixed a bug in Django 4.0 that caused a crash of `QuerySet.aggregate()` after `annotate()` on an aggregate function with a `default` (#33468).
- Fixed a regression in Django 4.0 that caused a crash of `makemigrations` when renaming a field of a renamed model (#33480).

Django 4.0.1 release notes

January 4, 2022

Django 4.0.1 fixes one security issue with severity “medium” , two security issues with severity “low” , and several bugs in 4.0.

CVE-2021-45115: Denial-of-service possibility in `UserAttributeSimilarityValidator`

`UserAttributeSimilarityValidator` incurred significant overhead evaluating submitted password that were artificially large in relative to the comparison values. On the assumption that access to user registration was unrestricted this provided a potential vector for a denial-of-service attack.

In order to mitigate this issue, relatively long values are now ignored by `UserAttributeSimilarityValidator`.

This issue has severity “medium” according to the [Django security policy](#).

CVE-2021-45116: Potential information disclosure in `dictsort` template filter

Due to leveraging the Django Template Language’s variable resolution logic, the `dictsort` template filter was potentially vulnerable to information disclosure or unintended method calls, if passed a suitably crafted key.

In order to avoid this possibility, `dictsort` now works with a restricted resolution logic, that will not call methods, nor allow indexing on dictionaries.

As a reminder, all untrusted user input should be validated before use.

This issue has severity “low” according to the [Django security policy](#).

CVE-2021-45452: Potential directory-traversal via `Storage.save()`

`Storage.save()` allowed directory-traversal if directly passed suitably crafted file names.

This issue has severity “low” according to the [Django security policy](#).

Bugfixes

- Fixed a regression in Django 4.0 that caused a crash of `assertFormsetError()` on a formset named `form` ([#33346](#)).
- Fixed a bug in Django 4.0 that caused a crash on booleans with the `RedisCache` backend ([#33361](#)).
- Relaxed the check added in Django 4.0 to reallow use of a duck-typed `HttpRequest` in `django.views.decorators.cache.cache_control()` and `never_cache()` decorators ([#33350](#)).

- Fixed a regression in Django 4.0 that caused creating bogus migrations for models that reference swappable models such as `auth.User` (#33366).
- Fixed a long standing bug in `Geometry Collections` and `Polygon` that caused a crash on some platforms (reported on macOS based on the ARM64 architecture) (#32600).

Django 4.0 release notes

December 7, 2021

Welcome to Django 4.0!

These release notes cover the [new features](#), as well as some [backwards incompatible changes](#) you'll want to be aware of when upgrading from Django 3.2 or earlier. We've begun the [deprecation process](#) for some [features](#).

See the [How to upgrade Django to a newer version](#) guide if you're updating an existing project.

Python compatibility

Django 4.0 supports Python 3.8, 3.9, and 3.10. We highly recommend and only officially support the latest release of each series.

The Django 3.2.x series is the last to support Python 3.6 and 3.7.

What's new in Django 4.0

`zoneinfo` default timezone implementation

The Python standard library's `zoneinfo` is now the default timezone implementation in Django.

This is the next step in the migration from using `pytz` to using `zoneinfo`. Django 3.2 allowed the use of non-`pytz` time zones. Django 4.0 makes `zoneinfo` the default implementation. Support for `pytz` is now deprecated and will be removed in Django 5.0.

`zoneinfo` is part of the Python standard library from Python 3.9. The `backports.zoneinfo` package is automatically installed alongside Django if you are using Python 3.8.

The move to `zoneinfo` should be largely transparent. Selection of the current timezone, conversion of date-time instances to the current timezone in forms and templates, as well as operations on aware datetimes in UTC are unaffected.

However, if you are working with non-UTC time zones, and using the `pytz.normalize()` and `pytz.localize()` APIs, possibly with the `TIME_ZONE` setting, you will need to audit your code, since `pytz` and `zoneinfo` are not entirely equivalent.

To give time for such an audit, the transitional `USE_DEPRECATED_PYTZ` setting allows continued use of `pytz` during the 4.x release cycle. This setting will be removed in Django 5.0.

In addition, a `pytz_deprecation_shim` package, created by the `zoneinfo` author, can be used to assist with the migration from `pytz`. This package provides shims to help you safely remove `pytz`, and has a detailed [migration guide](#) showing how to move to the new `zoneinfo` APIs.

Using `pytz_deprecation_shim` and the `USE_DEPRECATED_PYTZ` transitional setting is recommended if you need a gradual update path.

Functional unique constraints

The new `*expressions` positional argument of `UniqueConstraint()` enables creating functional unique constraints on expressions and database functions. For example:

```
from django.db import models
from django.db.models import UniqueConstraint
from django.db.models.functions import Lower

class MyModel(models.Model):
    first_name = models.CharField(max_length=255)
    last_name = models.CharField(max_length=255)

    class Meta:
        constraints = [
            UniqueConstraint(
                Lower("first_name"),
                Lower("last_name").desc(),
                name="first_last_name_unique",
            ),
        ]
```

Functional unique constraints are added to models using the `Meta.constraints` option.

scrypt password hasher

The new `scrypt password hasher` is more secure and recommended over PBKDF2. However, it's not the default as it requires OpenSSL 1.1+ and more memory.

Redis cache backend

The new `django.core.cache.backends.redis.RedisCache` cache backend provides built-in support for caching with Redis. `redis-py` 3.0.0 or higher is required. For more details, see the [documentation on caching with Redis in Django](#).

Template based form rendering

Forms, *Formsets*, and *ErrorList* are now rendered using the template engine to enhance customization. See the new `render()`, `get_context()`, and `template_name` for Form and `formset rendering` for Formset.

Minor features

`django.contrib.admin`

- The `admin/base.html` template now has a new block `header` which contains the admin site header.
- The new `ModelAdmin.get_formset_kwargs()` method allows customizing the keyword arguments passed to the constructor of a formset.
- The navigation sidebar now has a quick filter toolbar.
- The new context variable `model` which contains the model class for each model is added to the `AdminSite.each_context()` method.
- The new `ModelAdmin.search_help_text` attribute allows specifying a descriptive text for the search box.
- The `InlineModelAdmin.verbose_name_plural` attribute now fallbacks to the `InlineModelAdmin.verbose_name + 's'`.
- jQuery is upgraded from version 3.5.1 to 3.6.0.

`django.contrib.admindocs`

- The `admindocs` now allows esoteric setups where `ROOT_URLCONF` is not a string.
- The model section of the `admindocs` now shows cached properties.

`django.contrib.auth`

- The default iteration count for the PBKDF2 password hasher is increased from 260,000 to 320,000.
- The new `LoginView.next_page` attribute and `get_default_redirect_url()` method allow customizing the redirect after login.

`django.contrib.gis`

- Added support for SpatiaLite 5.
- `GDALRaster` now allows creating rasters in any GDAL virtual filesystem.
- The new `GISModelAdmin` class allows customizing the widget used for `GeometryField`. This is encouraged instead of deprecated `GeoModelAdmin` and `OSMGeoAdmin`.

`django.contrib.postgres`

- The PostgreSQL backend now supports connecting by a service name. See [PostgreSQL connection settings](#) for more details.
- The new `AddConstraintNotValid` operation allows creating check constraints on PostgreSQL without verifying that all existing rows satisfy the new constraint.
- The new `ValidateConstraint` operation allows validating check constraints which were created using `AddConstraintNotValid` on PostgreSQL.
- The new `ArraySubquery()` expression allows using subqueries to construct lists of values on PostgreSQL.
- The new `trigram_word_similar` lookup, and the `TrigramWordDistance()` and `TrigramWordSimilarity()` expressions allow using trigram word similarity.

`django.contrib.staticfiles`

- `ManifestStaticFilesStorage` now replaces paths to JavaScript source map references with their hashed counterparts.
- The new `manifest_storage` argument of `ManifestFilesMixin` and `ManifestStaticFilesStorage` allows customizing the manifest file storage.

Cache

- The new async API for `django.core.cache.backends.base.BaseCache` begins the process of making cache backends async-compatible. The new async methods all have a prefixed names, e.g. `aadd()`, `aget()`, `aset()`, `aget_or_set()`, or `adelete_many()`.

Going forward, the `a` prefix will be used for async variants of methods generally.

CSRF

- CSRF protection now consults the `Origin` header, if present. To facilitate this, some changes to the `CSRF_TRUSTED_ORIGINS` setting are required.

Forms

- `ModelChoiceField` now includes the provided value in the `params` argument of a raised `ValidationError` for the `invalid_choice` error message. This allows custom error messages to use the `%(value)s` placeholder.
- `BaseFormSet` now renders non-form errors with an additional class of `nonform` to help distinguish them from form-specific errors.
- `BaseFormSet` now allows customizing the widget used when deleting forms via `can_delete` by setting the `deletion_widget` attribute or overriding `get_deletion_widget()` method.

Internationalization

- Added support and translations for the Malay language.

Generic Views

- `DeleteView` now uses `FormMixin`, allowing you to provide a `Form` subclass, with a checkbox for example, to confirm deletion. In addition, this allows `DeleteView` to function with `django.contrib.messages.views.SuccessMessageMixin`.

In accordance with `FormMixin`, object deletion for POST requests is handled in `form_valid()`. Custom delete logic in `delete()` handlers should be moved to `form_valid()`, or a shared helper method, as needed.

Logging

- The alias of the database used in an SQL call is now passed as extra context along with each message to the `django.db.backends` logger.

Management Commands

- The `runserver` management command now supports the `--skip-checks` option.
- On PostgreSQL, `dbshell` now supports specifying a password file.
- The `shell` command now respects `sys.__interactivehook__` at startup. This allows loading shell history between interactive sessions. As a consequence, `readline` is no longer loaded if running in isolated mode.
- The new `BaseCommand.suppressed_base_arguments` attribute allows suppressing unsupported default command options in the help output.
- The new `startapp --exclude` and `startproject --exclude` options allow excluding directories from the template.

Models

- New `QuerySet.contains(obj)` method returns whether the queryset contains the given object. This tries to perform the query in the simplest and fastest way possible.
- The new `precision` argument of the `Round()` database function allows specifying the number of decimal places after rounding.
- `QuerySet.bulk_create()` now sets the primary key on objects when using SQLite 3.35+.
- `DurationField` now supports multiplying and dividing by scalar values on SQLite.
- `QuerySet.bulk_update()` now returns the number of objects updated.
- The new `Expression.empty_result_set_value` attribute allows specifying a value to return when the function is used over an empty result set.
- The `skip_locked` argument of `QuerySet.select_for_update()` is now allowed on MariaDB 10.6+.
- `Lookup` expressions may now be used in `QuerySet` annotations, aggregations, and directly in filters.
- The new `default` argument for built-in aggregates allows specifying a value to be returned when the queryset (or grouping) contains no entries, rather than `None`.

Requests and Responses

- The `SecurityMiddleware` now adds the Cross-Origin Opener Policy header with a value of 'same-origin' to prevent cross-origin popups from sharing the same browsing context. You can prevent this header from being added by setting the `SECURE_CROSS_ORIGIN_OPENER_POLICY` setting to `None`.

Signals

- The new `stdout` argument for `pre_migrate()` and `post_migrate()` signals allows redirecting output to a stream-like object. It should be preferred over `sys.stdout` and `print()` when emitting verbose output in order to allow proper capture when testing.

Templates

- `floatformat` template filter now allows using the `u` suffix to force disabling localization.

Tests

- The new `serialized_aliases` argument of `django.test.utils.setup_databases()` determines which `DATABASES` aliases test databases should have their state serialized to allow usage of the `serialized_rollback` feature.
- Django test runner now supports a `--buffer` option with parallel tests.
- The new `logger` argument to `DiscoverRunner` allows a Python `logger` to be used for logging.
- The new `DiscoverRunner.log()` method provides a way to log messages that uses the `DiscoverRunner.logger`, or prints to the console if not set.
- Django test runner now supports a `--shuffle` option to execute tests in a random order.
- The `test --parallel` option now supports the value `auto` to run one test process for each processor core.
- `TestCase.captureOnCommitCallbacks()` now captures new callbacks added while executing `transaction.on_commit()` callbacks.

Backwards incompatible changes in 4.0

Database backend API

This section describes changes that may be needed in third-party database backends.

- `DatabaseOperations.year_lookup_bounds_for_date_field()` and `year_lookup_bounds_for_datetime_field()` methods now take the optional `iso_year` argument in order to support bounds for ISO-8601 week-numbering years.
- The second argument of `DatabaseSchemaEditor._unique_sql()` and `_create_unique_sql()` methods is now `fields` instead of `columns`.

`django.contrib.gis`

- Support for PostGIS 2.3 is removed.
- Support for GDAL 2.0 and GEOS 3.5 is removed.

Dropped support for PostgreSQL 9.6

Upstream support for PostgreSQL 9.6 ends in November 2021. Django 4.0 supports PostgreSQL 10 and higher. Also, the minimum supported version of `psycopg2` is increased from 2.5.4 to 2.8.4, as `psycopg2` 2.8.4 is the first release to support Python 3.8.

Dropped support for Oracle 12.2 and 18c

Upstream support for Oracle 12.2 ends in March 2022 and for Oracle 18c it ends in June 2021. Django 3.2 will be supported until April 2024. Django 4.0 officially supports Oracle 19c.

`CSRF_TRUSTED_ORIGINS` changes

Format change

Values in the `CSRF_TRUSTED_ORIGINS` setting must include the scheme (e.g. `'http://'` or `'https://'`) instead of only the hostname.

Also, values that started with a dot, must now also include an asterisk before the dot. For example, change `'.example.com'` to `'https://*.example.com'`.

A system check detects any required changes.

Configuring it may now be required

As CSRF protection now consults the `Origin` header, you may need to set `CSRF_TRUSTED_ORIGINS`, particularly if you allow requests from subdomains by setting `CSRF_COOKIE_DOMAIN` (or `SESSION_COOKIE_DOMAIN` if `CSRF_USE_SESSIONS` is enabled) to a value starting with a dot.

`SecurityMiddleware` no longer sets the X-XSS-Protection header

The `SecurityMiddleware` no longer sets the X-XSS-Protection header if the `SECURE_BROWSER_XSS_FILTER` setting is `True`. The setting is removed.

Most modern browsers don't honor the X-XSS-Protection HTTP header. You can use `Content-Security-Policy` without allowing `'unsafe-inline'` scripts instead.

If you want to support legacy browsers and set the header, use this line in a custom middleware:

```
response.headers.setdefault("X-XSS-Protection", "1; mode=block")
```

Migrations autodetector changes

The migrations autodetector now uses model states instead of model classes. Also, migration operations for `ForeignKey` and `ManyToManyField` fields no longer specify attributes which were not passed to the fields during initialization.

As a side-effect, running `makemigrations` might generate no-op `AlterField` operations for `ManyToManyField` and `ForeignKey` fields in some cases.

`DeleteView` changes

`DeleteView` now uses `FormMixin` to handle POST requests. As a consequence, any custom deletion logic in `delete()` handlers should be moved to `form_valid()`, or a shared helper method, if required.

Table and column naming scheme changes on Oracle

Django 4.0 inadvertently changed the table and column naming scheme on Oracle. This causes errors for models and fields with names longer than 30 characters. Unfortunately, renaming some Oracle tables and columns is required. Use the upgrade script in [33789](#) to generate `RENAME` statements to change naming scheme.

Miscellaneous

- Support for `cx_Oracle < 7.0` is removed.
- To allow serving a Django site on a subpath without changing the value of `STATIC_URL`, the leading slash is removed from that setting (now `'static/'`) in the default `startproject` template.
- The `AdminSite` method for the admin index view is no longer decorated with `never_cache` when accessed directly, rather than via the recommended `AdminSite.urls` property, or `AdminSite.get_urls()` method.
- Unsupported operations on a sliced queryset now raise `TypeError` instead of `AssertionError`.
- The undocumented `django.test.runner.reorder_suite()` function is renamed to `reorder_tests()`. It now accepts an iterable of tests rather than a test suite, and returns an iterator of tests.
- Calling `FileSystemStorage.delete()` with an empty `name` now raises `ValueError` instead of `AssertionError`.
- Calling `EmailMultiAlternatives.attach_alternative()` or `EmailMessage.attach()` with an invalid content or mimetype arguments now raise `ValueError` instead of `AssertionError`.
- `assertHTMLEqual()` no longer considers a non-boolean attribute without a value equal to an attribute with the same name and value.
- Tests that fail to load, for example due to syntax errors, now always match when using `test --tag`.
- The undocumented `django.contrib.admin.utils.lookup_needs_distinct()` function is renamed to `lookup_spawns_duplicates()`.
- The undocumented `HttpRequest.get_raw_uri()` method is removed. The `HttpRequest.build_absolute_uri()` method may be a suitable alternative.
- The `object` argument of undocumented `ModelAdmin.log_addition()`, `log_change()`, and `log_deletion()` methods is renamed to `obj`.
- `RssFeed`, `Atom1Feed`, and their subclasses now emit elements with no content as self-closing tags.
- `NodeList.render()` no longer casts the output of `render()` method for individual nodes to a string. `Node.render()` should always return a string as documented.
- The `where_class` property of `django.db.models.sql.query.Query` and the `where_class` argument to the private `get_extra_restriction()` method of `ForeignObject` and `ForeignObjectRel` are removed. If needed, initialize `django.db.models.sql.where.WhereNode` instead.
- The `filter_clause` argument of the undocumented `Query.add_filter()` method is replaced by two positional arguments `filter_lhs` and `filter_rhs`.
- `CsrfViewMiddleware` now uses `request.META['CSRF_COOKIE_NEEDS_UPDATE']` in place of `request.META['CSRF_COOKIE_USED']`, `request.csrf_cookie_needs_reset`, and `response.csrf_cookie_set`

to track whether the CSRF cookie should be sent. This is an undocumented, private API.

- The undocumented `TRANSLATOR_COMMENT_MARK` constant is moved from `django.template.base` to `django.utils.translation.template`.
- The `real_apps` argument of the undocumented `django.db.migrations.state.ProjectState.__init__()` method must now be a set if provided.
- `RadioSelect` and `CheckboxSelectMultiple` widgets are now rendered in `<div>` tags so they are announced more concisely by screen readers. If you need the previous behavior, [override the widget template](#) with the appropriate template from Django 3.2.
- The `floatformat` template filter no longer depends on the `USE_L10N` setting and always returns localized output. Use the `u` suffix to disable localization.
- The default value of the `USE_L10N` setting is changed to `True`. See the [Localization](#) section above for more details.
- As part of the [move to zoneinfo](#), `django.utils.timezone.utc` is changed to alias `datetime.timezone.utc`.
- The minimum supported version of `asgiref` is increased from 3.3.2 to 3.4.1.

Features deprecated in 4.0

Use of `pytz` time zones

As part of the [move to zoneinfo](#), use of `pytz` time zones is deprecated.

Accordingly, the `is_dst` arguments to the following are also deprecated:

- `django.db.models.query.QuerySet.datetimes()`
- `django.db.models.functions.Trunc()`
- `django.db.models.functions.TruncSecond()`
- `django.db.models.functions.TruncMinute()`
- `django.db.models.functions.TruncHour()`
- `django.db.models.functions.TruncDay()`
- `django.db.models.functions.TruncWeek()`
- `django.db.models.functions.TruncMonth()`
- `django.db.models.functions.TruncQuarter()`
- `django.db.models.functions.TruncYear()`
- `django.utils.timezone.make_aware()`

Support for use of `pytz` will be removed in Django 5.0.

Time zone support

In order to follow good practice, the default value of the `USE_TZ` setting will change from `False` to `True`, and time zone support will be enabled by default, in Django 5.0.

Note that the default `settings.py` file created by `django-admin startproject` includes `USE_TZ = True` since Django 1.4.

You can set `USE_TZ` to `False` in your project settings before then to opt-out.

Localization

In order to follow good practice, the default value of the `USE_L10N` setting is changed from `False` to `True`.

Moreover `USE_L10N` is deprecated as of this release. Starting with Django 5.0, by default, any date or number displayed by Django will be localized.

The `{% localize %}` tag and the `localize/unlocalize` filters will still be honored by Django.

Miscellaneous

- `SERIALIZE` test setting is deprecated as it can be inferred from the `databases` with the `serialized_rollback` option enabled.
- The undocumented `django.utils.baseconv` module is deprecated.
- The undocumented `django.utils.datetime_safe` module is deprecated.
- The default sitemap protocol for sitemaps built outside the context of a request will change from `'http'` to `'https'` in Django 5.0.
- The `extra_tests` argument for `DiscoverRunner.build_suite()` and `DiscoverRunner.run_tests()` is deprecated.
- The `ArrayAgg`, `JSONBAgg`, and `StringAgg` aggregates will return `None` when there are no rows instead of `[]`, `[]`, and `' '` respectively in Django 5.0. If you need the previous behavior, explicitly set `default` to `Value([])`, `Value('[]')`, or `Value('')`.
- The `django.contrib.gis.admin.GeoModelAdmin` and `OSMGeoAdmin` classes are deprecated. Use `ModelAdmin` and `GISModelAdmin` instead.
- Since form rendering now uses the template engine, the undocumented `BaseForm._html_output()` helper method is deprecated.
- The ability to return a `str` from `ErrorList` and `ErrorDict` is deprecated. It is expected these methods return a `SafeString`.

Features removed in 4.0

These features have reached the end of their deprecation cycle and are removed in Django 4.0.

See [Features deprecated in 3.0](#) for details on these changes, including how to remove usage of these features.

- `django.utils.http.urlquote()`, `urlquote_plus()`, `urlunquote()`, and `urlunquote_plus()` are removed.
- `django.utils.encoding.force_text()` and `smart_text()` are removed.
- `django.utils.translation.ugettext()`, `ugettext_lazy()`, `ugettext_noop()`, `ungettext()`, and `ungettext_lazy()` are removed.
- `django.views.i18n.set_language()` doesn't set the user language in `request.session` (`key_language`).
- `alias=None` is required in the signature of `django.db.models.Expression.get_group_by_cols()` subclasses.
- `django.utils.text.unescape_entities()` is removed.
- `django.utils.http.is_safe_url()` is removed.

See [Features deprecated in 3.1](#) for details on these changes, including how to remove usage of these features.

- The `PASSWORD_RESET_TIMEOUT_DAYS` setting is removed.
- The `isnull` lookup no longer allows using non-boolean values as the right-hand side.
- The `django.db.models.query_utils.InvalidQuery` exception class is removed.
- The `django-admin.py` entry point is removed.
- The `HttpRequest.is_ajax()` method is removed.
- Support for the pre-Django 3.1 encoding format of cookies values used by `django.contrib.messages.storage.cookie.CookieStorage` is removed.
- Support for the pre-Django 3.1 password reset tokens in the admin site (that use the SHA-1 hashing algorithm) is removed.
- Support for the pre-Django 3.1 encoding format of sessions is removed.
- Support for the pre-Django 3.1 `django.core.signing.Signer` signatures (encoded with the SHA-1 algorithm) is removed.
- Support for the pre-Django 3.1 `django.core.signing.dumps()` signatures (encoded with the SHA-1 algorithm) in `django.core.signing.loads()` is removed.
- Support for the pre-Django 3.1 user sessions (that use the SHA-1 algorithm) is removed.
- The `get_response` argument for `django.utils.deprecation.MiddlewareMixin.__init__()` is required and doesn't accept `None`.

- The `providing_args` argument for `django.dispatch.Signal` is removed.
- The `length` argument for `django.utils.crypto.get_random_string()` is required.
- The `list` message for `ModelMultipleChoiceField` is removed.
- Support for passing raw column aliases to `QuerySet.order_by()` is removed.
- The `NullBooleanField` model field is removed, except for support in historical migrations.
- `django.conf.urls.url()` is removed.
- The `django.contrib.postgres.fields.JSONField` model field is removed, except for support in historical migrations.
- `django.contrib.postgres.fields.jsonb.KeyTransform` and `django.contrib.postgres.fields.jsonb.KeyTextTransform` are removed.
- `django.contrib.postgres.forms.JSONField` is removed.
- The `{% ifequal %}` and `{% ifnotequal %}` template tags are removed.
- The `DEFAULT_HASHING_ALGORITHM` transitional setting is removed.

9.1.4 3.2 release

Django 3.2.20 release notes

July 3, 2023

Django 3.2.20 fixes a security issue with severity “moderate” in 3.2.19.

CVE-2023-36053: Potential regular expression denial of service vulnerability in EmailValidator/URLValidator

`EmailValidator` and `URLValidator` were subject to potential regular expression denial of service attack via a very large number of domain name labels of emails and URLs.

Django 3.2.19 release notes

May 3, 2023

Django 3.2.19 fixes a security issue with severity “low” in 3.2.18.

CVE-2023-31047: Potential bypass of validation when uploading multiple files using one form field

Uploading multiple files using one form field has never been supported by `forms.FileField` or `forms.ImageField` as only the last uploaded file was validated. Unfortunately, [Uploading multiple files](#) topic suggested otherwise.

In order to avoid the vulnerability, `ClearableFileInput` and `FileInput` form widgets now raise `ValueError` when the `multiple` HTML attribute is set on them. To prevent the exception and keep the old behavior, set `allow_multiple_selected` to `True`.

For more details on using the new attribute and handling of multiple files through a single field, see [Uploading multiple files](#).

Django 3.2.18 release notes

February 14, 2023

Django 3.2.18 fixes a security issue with severity “moderate” in 3.2.17.

CVE-2023-24580: Potential denial-of-service vulnerability in file uploads

Passing certain inputs to multipart forms could result in too many open files or memory exhaustion, and provided a potential vector for a denial-of-service attack.

The number of files parts parsed is now limited via the new `DATA_UPLOAD_MAX_NUMBER_FILES` setting.

Django 3.2.17 release notes

February 1, 2023

Django 3.2.17 fixes a security issue with severity “moderate” in 3.2.16.

CVE-2023-23969: Potential denial-of-service via Accept-Language headers

The parsed values of `Accept-Language` headers are cached in order to avoid repetitive parsing. This leads to a potential denial-of-service vector via excessive memory usage if large header values are sent.

In order to avoid this vulnerability, the `Accept-Language` header is now parsed up to a maximum length.

Django 3.2.16 release notes

October 4, 2022

Django 3.2.16 fixes a security issue with severity “medium” in 3.2.15.

CVE-2022-41323: Potential denial-of-service vulnerability in internationalized URLs

Internationalized URLs were subject to potential denial of service attack via the locale parameter.

Django 3.2.15 release notes

August 3, 2022

Django 3.2.15 fixes a security issue with severity “high” in 3.2.14.

CVE-2022-36359: Potential reflected file download vulnerability in `FileResponse`

An application may have been vulnerable to a reflected file download (RFD) attack that sets the Content-Disposition header of a *FileResponse* when the `filename` was derived from user-supplied input. The `filename` is now escaped to avoid this possibility.

Django 3.2.14 release notes

July 4, 2022

Django 3.2.14 fixes a security issue with severity “high” in 3.2.13.

CVE-2022-34265: Potential SQL injection via `Trunc(kind)` and `Extract(lookup_name)` arguments

Trunc() and *Extract()* database functions were subject to SQL injection if untrusted data was used as a `kind/lookup_name` value.

Applications that constrain the lookup name and kind choice to a known safe list are unaffected.

Django 3.2.13 release notes

April 11, 2022

Django 3.2.13 fixes two security issues with severity “high” in 3.2.12 and a regression in 3.2.4.

CVE-2022-28346: Potential SQL injection in `QuerySet.annotate()`, `aggregate()`, and `extra()`

`QuerySet.annotate()`, `aggregate()`, and `extra()` methods were subject to SQL injection in column aliases, using a suitably crafted dictionary, with dictionary expansion, as the `**kwargs` passed to these methods.

CVE-2022-28347: Potential SQL injection via `QuerySet.explain(**options)` on PostgreSQL

`QuerySet.explain()` method was subject to SQL injection in option names, using a suitably crafted dictionary, with dictionary expansion, as the `**options` argument.

Bugfixes

- Fixed a regression in Django 3.2.4 that caused the auto-reloader to no longer detect changes when the `DIRS` option of the `TEMPLATES` setting contained an empty string (#33628).

Django 3.2.12 release notes

February 1, 2022

Django 3.2.12 fixes two security issues with severity “medium” in 3.2.11.

CVE-2022-22818: Possible XSS via `{% debug %}` template tag

The `{% debug %}` template tag didn’t properly encode the current context, posing an XSS attack vector.

In order to avoid this vulnerability, `{% debug %}` no longer outputs information when the `DEBUG` setting is `False`, and it ensures all context variables are correctly escaped when the `DEBUG` setting is `True`.

CVE-2022-23833: Denial-of-service possibility in file uploads

Passing certain inputs to multipart forms could result in an infinite loop when parsing files.

Django 3.2.11 release notes

January 4, 2022

Django 3.2.11 fixes one security issue with severity “medium” and two security issues with severity “low” in 3.2.10.

CVE-2021-45115: Denial-of-service possibility in `UserAttributeSimilarityValidator`

`UserAttributeSimilarityValidator` incurred significant overhead evaluating submitted password that were artificially large in relative to the comparison values. On the assumption that access to user registration was unrestricted this provided a potential vector for a denial-of-service attack.

In order to mitigate this issue, relatively long values are now ignored by `UserAttributeSimilarityValidator`.

This issue has severity “medium” according to the [Django security policy](#).

CVE-2021-45116: Potential information disclosure in `dictsort` template filter

Due to leveraging the Django Template Language’s variable resolution logic, the `dictsort` template filter was potentially vulnerable to information disclosure or unintended method calls, if passed a suitably crafted key.

In order to avoid this possibility, `dictsort` now works with a restricted resolution logic, that will not call methods, nor allow indexing on dictionaries.

As a reminder, all untrusted user input should be validated before use.

This issue has severity “low” according to the [Django security policy](#).

CVE-2021-45452: Potential directory-traversal via `Storage.save()`

`Storage.save()` allowed directory-traversal if directly passed suitably crafted file names.

This issue has severity “low” according to the [Django security policy](#).

Django 3.2.10 release notes

December 7, 2021

Django 3.2.10 fixes a security issue with severity “low” and a bug in 3.2.9.

CVE-2021-44420: Potential bypass of an upstream access control based on URL paths

HTTP requests for URLs with trailing newlines could bypass an upstream access control based on URL paths.

Bugfixes

- Fixed a regression in Django 3.2 that caused a crash of `setUpTestData()` with `BinaryField` on PostgreSQL, which is `memoryview`-backed ([#33333](#)).

Django 3.2.9 release notes

November 1, 2021

Django 3.2.9 fixes a bug in 3.2.8 and adds compatibility with Python 3.10.

Bugfixes

- Fixed a bug in Django 3.2 that caused a migration crash on SQLite when altering a field with a functional index ([#33194](#)).

Django 3.2.8 release notes

October 5, 2021

Django 3.2.8 fixes two bugs in 3.2.7.

Bugfixes

- Fixed a bug in Django 3.2 that caused incorrect links on read-only fields in the admin ([#33077](#)).
- Fixed a regression in Django 3.2 that caused incorrect selection of items across all pages when actions were placed both on the top and bottom of the admin change-list view ([#33083](#)).

Django 3.2.7 release notes

September 1, 2021

Django 3.2.7 fixes a bug in 3.2.6.

Bugfixes

- Fixed a regression in Django 3.2 that caused the incorrect offset extraction from fixed offset timezones ([#32992](#)).

Django 3.2.6 release notes

August 2, 2021

Django 3.2.6 fixes several bugs in 3.2.5.

Bugfixes

- Fixed a regression in Django 3.2 that caused a crash validating "NaN" input with a `forms.DecimalField` when additional constraints, e.g. `max_value`, were specified ([#32949](#)).
- Fixed a bug in Django 3.2 where a system check would crash on a model with a reverse many-to-many relation inherited from a parent class ([#32947](#)).

Django 3.2.5 release notes

July 1, 2021

Django 3.2.5 fixes a security issue with severity “high” and several bugs in 3.2.4. Also, the latest string translations from Transifex are incorporated.

CVE-2021-35042: Potential SQL injection via unsanitized `QuerySet.order_by()` input

Unsanitized user input passed to `QuerySet.order_by()` could bypass intended column reference validation in path marked for deprecation resulting in a potential SQL injection even if a deprecation warning is emitted.

As a mitigation the strict column reference validation was restored for the duration of the deprecation period. This regression appeared in 3.1 as a side effect of fixing [#31426](#).

The issue is not present in the main branch as the deprecated path has been removed.

Bugfixes

- Fixed a regression in Django 3.2 that caused a crash of `QuerySet.values_list(..., named=True)` after `prefetch_related()` ([#32812](#)).
- Fixed a bug in Django 3.2 that caused a migration crash on MySQL 8.0.13+ when altering `BinaryField`, `JSONField`, or `TextField` to non-nullable ([#32503](#)).
- Fixed a regression in Django 3.2 that caused a migration crash on MySQL 8.0.13+ when adding nullable `BinaryField`, `JSONField`, or `TextField` with a default value ([#32832](#)).
- Fixed a bug in Django 3.2 where a system check would crash on a model with an invalid `app_label` ([#32863](#)).

Django 3.2.4 release notes

June 2, 2021

Django 3.2.4 fixes two security issues and several bugs in 3.2.3.

CVE-2021-33203: Potential directory traversal via `admindocs`

Staff members could use the `admindocs` `TemplateDetailView` view to check the existence of arbitrary files. Additionally, if (and only if) the default `admindocs` templates have been customized by the developers to also expose the file contents, then not only the existence but also the file contents would have been exposed.

As a mitigation, path sanitation is now applied and only files within the template root directories can be loaded.

CVE-2021-33571: Possible indeterminate SSRF, RFI, and LFI attacks since validators accepted leading zeros in IPv4 addresses

`URLValidator`, `validate_ipv4_address()`, and `validate_ipv6_address()` didn't prohibit leading zeros in octal literals. If you used such values you could suffer from indeterminate SSRF, RFI, and LFI attacks.

`validate_ipv4_address()` and `validate_ipv6_address()` validators were not affected on Python 3.9.5+.

Bugfixes

- Fixed a bug in Django 3.2 where a final catch-all view in the admin didn't respect the server-provided value of `SCRIPT_NAME` when redirecting unauthenticated users to the login page (#32754).
- Fixed a bug in Django 3.2 where a system check would crash on an abstract model (#32733).
- Prevented unnecessary initialization of unused caches following a regression in Django 3.2 (#32747).
- Fixed a crash in Django 3.2 that could occur when running `mod_wsgi` with the recommended settings while the Windows `colorama` library was installed (#32740).
- Fixed a bug in Django 3.2 that would trigger the auto-reloader for template changes when directory paths were specified with strings (#32744).
- Fixed a regression in Django 3.2 that caused a crash of auto-reloader with `AttributeError`, e.g. inside a Conda environment (#32783).
- Fixed a regression in Django 3.2 that caused a loss of precision for operations with `DecimalField` on MySQL (#32793).

Django 3.2.3 release notes

May 13, 2021

Django 3.2.3 fixes several bugs in 3.2.2.

Bugfixes

- Prepared for `mysqlclient > 2.0.3` support (#32732).
- Fixed a regression in Django 3.2 that caused the incorrect filtering of querysets combined with the `|` operator (#32717).
- Fixed a regression in Django 3.2.1 where saving `FileField` would raise a `SuspiciousFileOperation` even when a custom `upload_to` returns a valid file path (#32718).

Django 3.2.2 release notes

May 6, 2021

Django 3.2.2 fixes a security issue and a bug in 3.2.1.

CVE-2021-32052: Header injection possibility since `URLValidator` accepted newlines in input on Python 3.9.5+

On Python 3.9.5+, `URLValidator` didn't prohibit newlines and tabs. If you used values with newlines in HTTP response, you could suffer from header injection attacks. Django itself wasn't vulnerable because `HttpResponse` prohibits newlines in HTTP headers.

Moreover, the `URLField` form field which uses `URLValidator` silently removes newlines and tabs on Python 3.9.5+, so the possibility of newlines entering your data only existed if you are using this validator outside of the form fields.

This issue was introduced by the [bpo-43882](#) fix.

Bugfixes

- Prevented, following a regression in Django 3.2.1, `makemigrations` from generating infinite migrations for a model with `Meta.ordering` contained `OrderBy` expressions (#32714).

Django 3.2.1 release notes

May 4, 2021

Django 3.2.1 fixes a security issue and several bugs in 3.2.

CVE-2021-31542: Potential directory-traversal via uploaded files

`MultiPartParser`, `UploadedFile`, and `FieldFile` allowed directory-traversal via uploaded files with suitably crafted file names.

In order to mitigate this risk, stricter basename and path sanitation is now applied.

Bugfixes

- Corrected detection of GDAL 3.2 on Windows ([#32544](#)).
- Fixed a bug in Django 3.2 where subclasses of `BigAutoField` and `SmallAutoField` were not allowed for the `DEFAULT_AUTO_FIELD` setting ([#32620](#)).
- Fixed a regression in Django 3.2 that caused a crash of `QuerySet.values()/values_list()` after `QuerySet.union()`, `intersection()`, and `difference()` when it was ordered by an unannotated field ([#32627](#)).
- Restored, following a regression in Django 3.2, displaying an exception message on the technical 404 debug page ([#32637](#)).
- Fixed a bug in Django 3.2 where a system check would crash on a reverse one-to-one relationships in `CheckConstraint.check` or `UniqueConstraint.condition` ([#32635](#)).
- Fixed a regression in Django 3.2 that caused a crash of `ModelAdmin.search_fields` when searching against phrases with unbalanced quotes ([#32649](#)).
- Fixed a bug in Django 3.2 where variable lookup errors were logged rendering the sitemap template if alternates were not defined ([#32648](#)).
- Fixed a regression in Django 3.2 that caused a crash when combining `Q()` objects which contains boolean expressions ([#32548](#)).
- Fixed a regression in Django 3.2 that caused a crash of `QuerySet.update()` on a queryset ordered by inherited or joined fields on MySQL and MariaDB ([#32645](#)).
- Fixed a regression in Django 3.2 that caused a crash when decoding a cookie value, used by `django.contrib.messages.storage.cookie.CookieStorage`, in the pre-Django 3.2 format ([#32643](#)).
- Fixed a regression in Django 3.2 that stopped the shift-key modifier selecting multiple rows in the admin changelist ([#32647](#)).

- Fixed a bug in Django 3.2 where a system check would crash on the `STATICFILES_DIRS` setting with a list of 2-tuples of `(prefix, path)` ([#32665](#)).
- Fixed a long standing bug involving queryset bitwise combination when used with subqueries that began manifesting in Django 3.2, due to a separate fix using `Exists` to `exclude()` multi-valued relationships ([#32650](#)).
- Fixed a bug in Django 3.2 where variable lookup errors were logged when rendering some admin templates ([#32681](#)).
- Fixed a bug in Django 3.2 where an admin changelist would crash when deleting objects filtered against multi-valued relationships ([#32682](#)). The admin changelist now uses `Exists()` instead of `QuerySet.distinct()` because calling `delete()` after `distinct()` is not allowed in Django 3.2 to address a data loss possibility.
- Fixed a regression in Django 3.2 where the calling process environment would not be passed to the `dbshell` command on PostgreSQL ([#32687](#)).
- Fixed a performance regression in Django 3.2 when building complex filters with subqueries ([#32632](#)). As a side-effect the private API to check `django.db.sql.query.Query` equality is removed.

Django 3.2 release notes

April 6, 2021

Welcome to Django 3.2!

These release notes cover the [new features](#), as well as some [backwards incompatible changes](#) you'll want to be aware of when upgrading from Django 3.1 or earlier. We've begun [the deprecation process for some features](#).

See the [How to upgrade Django to a newer version](#) guide if you're updating an existing project.

Django 3.2 is designated as a [long-term support release](#). It will receive security updates for at least three years after its release. Support for the previous LTS, Django 2.2, will end in April 2022.

Python compatibility

Django 3.2 supports Python 3.6, 3.7, 3.8, 3.9, and 3.10 (as of 3.2.9). We highly recommend and only officially support the latest release of each series.

What's new in Django 3.2

Automatic AppConfig discovery

Most pluggable applications define an *AppConfig* subclass in an `apps.py` submodule. Many define a `default_app_config` variable pointing to this class in their `__init__.py`.

When the `apps.py` submodule exists and defines a single *AppConfig* subclass, Django now uses that configuration automatically, so you can remove `default_app_config`.

`default_app_config` made it possible to declare only the application's path in *INSTALLED_APPS* (e.g. `'django.contrib.admin'`) rather than the app config's path (e.g. `'django.contrib.admin.apps.AdminConfig'`). It was introduced for backwards-compatibility with the former style, with the intent to switch the ecosystem to the latter, but the switch didn't happen.

With automatic AppConfig discovery, `default_app_config` is no longer needed. As a consequence, it's deprecated.

See [Configuring applications](#) for full details.

Customizing type of auto-created primary keys

When defining a model, if no field in a model is defined with *primary_key=True* an implicit primary key is added. The type of this implicit primary key can now be controlled via the *DEFAULT_AUTO_FIELD* setting and *AppConfig.default_auto_field* attribute. No more needing to override primary keys in all models.

Maintaining the historical behavior, the default value for *DEFAULT_AUTO_FIELD* is *AutoField*. Starting with 3.2 new projects are generated with *DEFAULT_AUTO_FIELD* set to *BigAutoField*. Also, new apps are generated with *AppConfig.default_auto_field* set to *BigAutoField*. In a future Django release the default value of *DEFAULT_AUTO_FIELD* will be changed to *BigAutoField*.

To avoid unwanted migrations in the future, either explicitly set *DEFAULT_AUTO_FIELD* to *AutoField*:

```
DEFAULT_AUTO_FIELD = "django.db.models.AutoField"
```

or configure it on a per-app basis:

```
from django.apps import AppConfig

class MyAppConfig(AppConfig):
    default_auto_field = "django.db.models.AutoField"
    name = "my_app"
```

or on a per-model basis:

```
from django.db import models

class MyModel(models.Model):
    id = models.AutoField(primary_key=True)
```

In anticipation of the changing default, a system check will provide a warning if you do not have an explicit setting for `DEFAULT_AUTO_FIELD`.

When changing the value of `DEFAULT_AUTO_FIELD`, migrations for the primary key of existing auto-created through tables cannot be generated currently. See the `DEFAULT_AUTO_FIELD` docs for details on migrating such tables.

Functional indexes

The new **expressions* positional argument of `Index()` enables creating functional indexes on expressions and database functions. For example:

```
from django.db import models
from django.db.models import F, Index, Value
from django.db.models.functions import Lower, Upper

class MyModel(models.Model):
    first_name = models.CharField(max_length=255)
    last_name = models.CharField(max_length=255)
    height = models.IntegerField()
    weight = models.IntegerField()

    class Meta:
        indexes = [
            Index(
                Lower("first_name"),
                Upper("last_name").desc(),
                name="first_last_name_idx",
            ),
            Index(
                F("height") / (F("weight") + Value(5)),
                name="calc_idx",
            ),
        ]
```

Functional indexes are added to models using the `Meta.indexes` option.

`pymemcache` support

The new `django.core.cache.backends.memcached.PyMemcacheCache` cache backend allows using the `pymemcache` library for memcached. `pymemcache` 3.4.0 or higher is required. For more details, see the [documentation on caching in Django](#).

New decorators for the admin site

The new `display()` decorator allows for easily adding options to custom display functions that can be used with `list_display` or `readonly_fields`.

Likewise, the new `action()` decorator allows for easily adding options to action functions that can be used with `actions`.

Using the `@display` decorator has the advantage that it is now possible to use the `@property` decorator when needing to specify attributes on the custom method. Prior to this it was necessary to use the `property()` function instead after assigning the required attributes to the method.

Using decorators has the advantage that these options are more discoverable as they can be suggested by completion utilities in code editors. They are merely a convenience and still set the same attributes on the functions under the hood.

Minor features

`django.contrib.admin`

- `ModelAdmin.search_fields` now allows searching against quoted phrases with spaces.
- Read-only related fields are now rendered as navigable links if target models are registered in the admin.
- The admin now supports theming, and includes a dark theme that is enabled according to browser settings. See [Theming support](#) for more details.
- `ModelAdmin.autocomplete_fields` now respects `ForeignKey.to_field` and `ForeignKey.limit_choices_to` when searching a related model.
- The admin now installs a final catch-all view that redirects unauthenticated users to the login page, regardless of whether the URL is otherwise valid. This protects against a potential model enumeration privacy issue.

Although not recommended, you may set the new `AdminSite.final_catch_all_view` to `False` to disable the catch-all view.

`django.contrib.auth`

- The default iteration count for the PBKDF2 password hasher is increased from 216,000 to 260,000.
- The default variant for the Argon2 password hasher is changed to Argon2id. `memory_cost` and `parallelism` are increased to 102,400 and 8 respectively to match the `argon2-cffi` defaults.

Increasing the `memory_cost` pushes the required memory from 512 KB to 100 MB. This is still rather conservative but can lead to problems in memory constrained environments. If this is the case, the existing hasher can be subclassed to override the defaults.

- The default salt entropy for the Argon2, MD5, PBKDF2, SHA-1 password hashers is increased from 71 to 128 bits.

`django.contrib.contenttypes`

- The new `absolute_max` argument for `generic_inlineformset_factory()` allows customizing the maximum number of forms that can be instantiated when supplying POST data. See [Limiting the maximum number of instantiated forms](#) for more details.
- The new `can_delete_extra` argument for `generic_inlineformset_factory()` allows removal of the option to delete extra forms. See `can_delete_extra` for more information.

`django.contrib.gis`

- The `GDALRaster.transform()` method now supports `SpatialReference`.
- The `DataSource` class now supports `pathlib.Path`.
- The `LayerMapping` class now supports `pathlib.Path`.

`django.contrib.postgres`

- The new `ExclusionConstraint.include` attribute allows creating covering exclusion constraints on PostgreSQL 12+.
- The new `ExclusionConstraint.opclasses` attribute allows setting PostgreSQL operator classes.
- The new `JSONBAgg.ordering` attribute determines the ordering of the aggregated elements.
- The new `JSONBAgg.distinct` attribute determines if aggregated values will be distinct.
- The `CreateExtension` operation now checks that the extension already exists in the database and skips the migration if so.
- The new `CreateCollation` and `RemoveCollation` operations allow creating and dropping collations on PostgreSQL. See [Managing collations using migrations](#) for more details.

- Lookups for *ArrayField* now allow (non-nested) arrays containing expressions as right-hand sides.
- The new *OpClass()* expression allows creating functional indexes on expressions with a custom operator class. See [Functional indexes](#) for more details.

`django.contrib.sitemaps`

- The new *Sitemap* attributes *alternates*, *languages* and *x_default* allow generating sitemap alternates to localized versions of your pages.

`django.contrib.syndication`

- The new `item_comments` hook allows specifying a comments URL per feed item.

Database backends

- Third-party database backends can now skip or mark as expected failures tests in Django's test suite using the new `DatabaseFeatures.django_test_skips` and `django_test_expected_failures` attributes.

Decorators

- The new *no_append_slash()* decorator allows individual views to be excluded from *APPEND_SLASH* URL normalization.

Error Reporting

- Custom *ExceptionReporter* subclasses can now define the *html_template_path* and *text_template_path* properties to override the templates used to render exception reports.

File Uploads

- The new *FileUploadHandler.upload_interrupted()* callback allows handling interrupted uploads.

Forms

- The new `absolute_max` argument for `formset_factory()`, `inlineformset_factory()`, and `modelformset_factory()` allows customizing the maximum number of forms that can be instantiated when supplying POST data. See [Limiting the maximum number of instantiated forms](#) for more details.
- The new `can_delete_extra` argument for `formset_factory()`, `inlineformset_factory()`, and `modelformset_factory()` allows removal of the option to delete extra forms. See [can_delete_extra](#) for more information.
- `BaseFormSet` now reports a user facing error, rather than raising an exception, when the management form is missing or has been tampered with. To customize this error message, pass the `error_messages` argument with the key `'missing_management_form'` when instantiating the formset.

Generic Views

- The `week_format` attributes of `WeekMixin` and `WeekArchiveView` now support the `'%V'` ISO 8601 week format.

Management Commands

- `loaddata` now supports fixtures stored in XZ archives (`.xz`) and LZMA archives (`.lzma`).
- `dumpdata` now can compress data in the `bz2`, `gz`, `lzma`, or `xz` formats.
- `makemigrations` can now be called without an active database connection. In that case, check for a consistent migration history is skipped.
- `BaseCommand.requires_system_checks` now supports specifying a list of tags. System checks registered in the chosen tags will be checked for errors prior to executing the command. In previous versions, either all or none of the system checks were performed.
- Support for colored terminal output on Windows is updated. Various modern terminal environments are automatically detected, and the options for enabling support in other cases are improved. See [Syntax coloring](#) for more details.

Migrations

- The new `Operation.migration_name_fragment` property allows providing a filename fragment that will be used to name a migration containing only that operation.
- Migrations now support serialization of pure and concrete path objects from `pathlib`, and `os.PathLike` instances.

Models

- The new `no_key` parameter for `QuerySet.select_for_update()`, supported on PostgreSQL, allows acquiring weaker locks that don't block the creation of rows that reference locked rows through a foreign key.
- `When()` expression now allows using the `condition` argument with lookups.
- The new `Index.include` and `UniqueConstraint.include` attributes allow creating covering indexes and covering unique constraints on PostgreSQL 11+.
- The new `UniqueConstraint.opclasses` attribute allows setting PostgreSQL operator classes.
- The `QuerySet.update()` method now respects the `order_by()` clause on MySQL and MariaDB.
- `FilteredRelation()` now supports nested relations.
- The `of` argument of `QuerySet.select_for_update()` is now allowed on MySQL 8.0.1+.
- `Value()` expression now automatically resolves its `output_field` to the appropriate `Field` subclass based on the type of its provided `value` for `bool`, `bytes`, `float`, `int`, `str`, `datetime.date`, `datetime.datetime`, `datetime.time`, `datetime.timedelta`, `decimal.Decimal`, and `uuid.UUID` instances. As a consequence, resolving an `output_field` for database functions and combined expressions may now crash with mixed types when using `Value()`. You will need to explicitly set the `output_field` in such cases.
- The new `QuerySet.alias()` method allows creating reusable aliases for expressions that don't need to be selected but are used for filtering, ordering, or as a part of complex expressions.
- The new `Collate` function allows filtering and ordering by specified database collations.
- The `field_name` argument of `QuerySet.in_bulk()` now accepts distinct fields if there's only one field specified in `QuerySet.distinct()`.
- The new `tzinfo` parameter of the `TruncDate` and `TruncTime` database functions allows truncating datetimes in a specific timezone.
- The new `db_collation` argument for `CharField` and `TextField` allows setting a database collation for the field.
- Added the `Random` database function.

- Aggregation functions, `F()`, `OuterRef()`, and other expressions now allow using transforms. See [Expressions can reference transforms](#) for details.
- The new `durable` argument for `atomic()` guarantees that changes made in the atomic block will be committed if the block exits without errors. A nested atomic block marked as durable will raise a `RuntimeError`.
- Added the `JSONObject` database function.

Pagination

- The new `django.core.paginator.Paginator.get_elided_page_range()` method allows generating a page range with some of the values elided. If there are a large number of pages, this can be helpful for generating a reasonable number of page links in a template.

Requests and Responses

- Response headers are now stored in `HttpResponse.headers`. This can be used instead of the original dict-like interface of `HttpResponse` objects. Both interfaces will continue to be supported. See [Setting header fields](#) for details.
- The new `headers` parameter of `HttpResponse`, `SimpleTemplateResponse`, and `TemplateResponse` allows setting response `headers` on instantiation.

Security

- The `SECRET_KEY` setting is now checked for a valid value upon first access, rather than when settings are first loaded. This enables running management commands that do not rely on the `SECRET_KEY` without needing to provide a value. As a consequence of this, calling `configure()` without providing a valid `SECRET_KEY`, and then going on to access `settings.SECRET_KEY` will now raise an `ImproperlyConfigured` exception.
- The new `Signer.sign_object()` and `Signer.unsign_object()` methods allow signing complex data structures. See [Protecting complex data structures](#) for more details.

Also, `signing.dumps()` and `loads()` become shortcuts for `TimestampSigner.sign_object()` and `unsign_object()`.

Serialization

- The new `JSONL` serializer allows using the JSON Lines format with `dumpdata` and `loaddata`. This can be useful for populating large databases because data is loaded line by line into memory, rather than being loaded all at once.

Signals

- `Signal.send_robust()` now logs exceptions.

Templates

- `floatformat` template filter now allows using the `g` suffix to force grouping by the `THOUSAND_SEPARATOR` for the active locale.
- Templates cached with `Cached template loaders` are now correctly reloaded in development.

Tests

- Objects assigned to class attributes in `TestCase.setUpTestData()` are now isolated for each test method. Such objects are now required to support creating deep copies with `copy.deepcopy()`. Assigning objects which don't support `deepcopy()` is deprecated and will be removed in Django 4.1.
- `DiscoverRunner` now enables `faulthandler` by default. This can be disabled by using the `test --no-faulthandler` option.
- `DiscoverRunner` and the `test` management command can now track timings, including database setup and total run time. This can be enabled by using the `test --timing` option.
- `Client` now preserves the request query string when following 307 and 308 redirects.
- The new `TestCase.captureOnCommitCallbacks()` method captures callback functions passed to `transaction.on_commit()` in a list. This allows you to test such callbacks without using the slower `TransactionTestCase`.
- `TransactionTestCase.assertQuerysetEqual()` now supports direct comparison against another queryset rather than being restricted to comparison against a list of string representations of objects when using the default value for the `transform` argument.

Utilities

- The new `depth` parameter of `django.utils.timesince.timesince()` and `django.utils.timesince.timeuntil()` functions allows specifying the number of adjacent time units to return.

Validators

- Built-in validators now include the provided value in the `params` argument of a raised *ValidationError*. This allows custom error messages to use the `%(value)s` placeholder.
- The *ValidationError* equality operator now ignores `messages` and `params` ordering.

Backwards incompatible changes in 3.2

Database backend API

This section describes changes that may be needed in third-party database backends.

- The new `DatabaseFeatures.introspected_field_types` property replaces these features:
 - `can_introspect_autofield`
 - `can_introspect_big_integer_field`
 - `can_introspect_binary_field`
 - `can_introspect_decimal_field`
 - `can_introspect_duration_field`
 - `can_introspect_ip_address_field`
 - `can_introspect_positive_integer_field`
 - `can_introspect_small_integer_field`
 - `can_introspect_time_field`
 - `introspected_big_auto_field_type`
 - `introspected_small_auto_field_type`
 - `introspected_boolean_field_type`
- To enable support for covering indexes (*Index.include*) and covering unique constraints (*UniqueConstraint.include*), set `DatabaseFeatures.supports_covering_indexes` to `True`.
- Third-party database backends must implement support for column database collations on `CharFields` and `TextFields` or set `DatabaseFeatures.supports_collation_on_charfield` and `DatabaseFeatures.supports_collation_on_textfield` to `False`. If non-deterministic collations are not supported, set `supports_non_deterministic_collations` to `False`.

- `DatabaseOperations.random_function_sql()` is removed in favor of the new *Random* database function.
- `DatabaseOperations.date_trunc_sql()` and `DatabaseOperations.time_trunc_sql()` now take the optional `tzname` argument in order to truncate in a specific timezone.
- `DatabaseClient.runshell()` now gets arguments and an optional dictionary with environment variables to the underlying command-line client from `DatabaseClient.settings_to_cmd_args_env()` method. Third-party database backends must implement `DatabaseClient.settings_to_cmd_args_env()` or override `DatabaseClient.runshell()`.
- Third-party database backends must implement support for functional indexes (*Index.expressions*) or set `DatabaseFeatures.supports_expression_indexes` to `False`. If `COLLATE` is not a part of the `CREATE INDEX` statement, set `DatabaseFeatures.collate_as_index_expression` to `True`.

`django.contrib.admin`

- Pagination links in the admin are now 1-indexed instead of 0-indexed, i.e. the query string for the first page is `?p=1` instead of `?p=0`.
- The new admin catch-all view will break URL patterns routed after the admin URLs and matching the admin URL prefix. You can either adjust your URL ordering or, if necessary, set *AdminSite.final_catch_all_view* to `False`, disabling the catch-all view. See *What's new in Django 3.2* for more details.
- Minified JavaScript files are no longer included with the admin. If you require these files to be minified, consider using a third party app or external build tool. The minified vendored JavaScript files packaged with the admin (e.g. `jquery.min.js`) are still included.
- *ModelAdmin.prepopulated_fields* no longer strips English stop words, such as `'a'` or `'an'`.

`django.contrib.gis`

- Support for PostGIS 2.2 is removed.
- The Oracle backend now clones polygons (and geometry collections containing polygons) before reorienting them and saving them to the database. They are no longer mutated in place. You might notice this if you use the polygons after a model is saved.

Dropped support for PostgreSQL 9.5

Upstream support for PostgreSQL 9.5 ends in February 2021. Django 3.2 supports PostgreSQL 9.6 and higher.

Dropped support for MySQL 5.6

The end of upstream support for MySQL 5.6 is April 2021. Django 3.2 supports MySQL 5.7 and higher.

Miscellaneous

- Django now supports non-pytz time zones, such as Python 3.9+’s `zoneinfo` module and its backport.
- The undocumented `SpatialiteOperations.proj4_version()` method is renamed to `proj_version()`.
- `slugify()` now removes leading and trailing dashes and underscores.
- The `intcomma` and `intword` template filters no longer depend on the `USE_L10N` setting.
- Support for `argon2-cffi < 19.1.0` is removed.
- The cache keys no longer includes the language when internationalization is disabled (`USE_I18N = False`) and localization is enabled (`USE_L10N = True`). After upgrading to Django 3.2 in such configurations, the first request to any previously cached value will be a cache miss.
- `ForeignKey.validate()` now uses `_base_manager` rather than `_default_manager` to check that related instances exist.
- When an application defines an `AppConfig` subclass in an `apps.py` submodule, Django now uses this configuration automatically, even if it isn’t enabled with `default_app_config`. Set `default = False` in the `AppConfig` subclass if you need to prevent this behavior. See [What’s new in Django 3.2](#) for more details.
- Instantiating an abstract model now raises `TypeError`.
- Keyword arguments to `setup_databases()` are now keyword-only.
- The undocumented `django.utils.http.limited_parse_qs1()` function is removed. Please use `urllib.parse.parse_qs1()` instead.
- `django.test.utils.TestContextDecorator` now uses `addCleanup()` so that cleanups registered in the `setUp()` method are called before `TestContextDecorator.disable()`.
- `SessionMiddleware` now raises a `SessionInterrupted` exception instead of `SuspiciousOperation` when a session is destroyed in a concurrent request.
- The `django.db.models.Field` equality operator now correctly distinguishes inherited field instances across models. Additionally, the ordering of such fields is now defined.

- The undocumented `django.core.files.locks.lock()` function now returns `False` if the file cannot be locked, instead of raising `BlockingIOError`.
- The password reset mechanism now invalidates tokens when the user email is changed.
- `makemessages` command no longer processes invalid locales specified using `makemessages --locale` option, when they contain hyphens ('-').
- The `django.contrib.auth.forms.ReadOnlyPasswordHashField` form field is now *disabled* by default. Therefore `UserChangeForm.clean_password()` is no longer required to return the initial value.
- The `cache.get_many()`, `get_or_set()`, `has_key()`, `incr()`, `decr()`, `incr_version()`, and `decr_version()` cache operations now correctly handle `None` stored in the cache, in the same way as any other value, instead of behaving as though the key didn't exist.

Due to a `python-memcached` limitation, the previous behavior is kept for the deprecated `MemcachedCache` backend.

- The minimum supported version of SQLite is increased from 3.8.3 to 3.9.0.
- `CookieStorage` now stores messages in the [RFC 6265](#) compliant format. Support for cookies that use the old format remains until Django 4.1.
- The minimum supported version of `asgiref` is increased from 3.2.10 to 3.3.2.

Features deprecated in 3.2

Miscellaneous

- Assigning objects which don't support creating deep copies with `copy.deepcopy()` to class attributes in `TestCase.setUpTestData()` is deprecated.
- Using a boolean value in `BaseCommand.requires_system_checks` is deprecated. Use `'__all__'` instead of `True`, and `[]` (an empty list) instead of `False`.
- The `whitelist` argument and `domain_whitelist` attribute of `EmailValidator` are deprecated. Use `allowlist` instead of `whitelist`, and `domain_allowlist` instead of `domain_whitelist`. You may need to rename `whitelist` in existing migrations.
- The `default_app_config` application configuration variable is deprecated, due to the now automatic `AppConfig` discovery. See [What's new in Django 3.2](#) for more details.
- Automatically calling `repr()` on a queryset in `TransactionTestCase.assertQuerysetEqual()`, when compared to string values, is deprecated. If you need the previous behavior, explicitly set `transform` to `repr`.
- The `django.core.cache.backends.memcached.MemcachedCache` backend is deprecated as `python-memcached` has some problems and seems to be unmaintained. Use `django.core.`

`cache.backends.memcached.PyMemcacheCache` or `django.core.cache.backends.memcached.PyLibMCCache` instead.

- The format of messages used by `django.contrib.messages.storage.cookie.CookieStorage` is different from the format generated by older versions of Django. Support for the old format remains until Django 4.1.

9.1.5 3.1 release

Django 3.1.14 release notes

December 7, 2021

Django 3.1.14 fixes a security issue with severity “low” in 3.1.13.

CVE-2021-44420: Potential bypass of an upstream access control based on URL paths

HTTP requests for URLs with trailing newlines could bypass an upstream access control based on URL paths.

Django 3.1.13 release notes

July 1, 2021

Django 3.1.13 fixes a security issue with severity “high” in 3.1.12.

CVE-2021-35042: Potential SQL injection via unsanitized `QuerySet.order_by()` input

Unsanitized user input passed to `QuerySet.order_by()` could bypass intended column reference validation in path marked for deprecation resulting in a potential SQL injection even if a deprecation warning is emitted.

As a mitigation the strict column reference validation was restored for the duration of the deprecation period. This regression appeared in 3.1 as a side effect of fixing [#31426](#).

The issue is not present in the main branch as the deprecated path has been removed.

Django 3.1.12 release notes

June 2, 2021

Django 3.1.12 fixes two security issues in 3.1.11.

CVE-2021-33203: Potential directory traversal via `admindocs`

Staff members could use the `admindocs` `TemplateDetailView` view to check the existence of arbitrary files. Additionally, if (and only if) the default `admindocs` templates have been customized by the developers to also expose the file contents, then not only the existence but also the file contents would have been exposed.

As a mitigation, path sanitation is now applied and only files within the template root directories can be loaded.

CVE-2021-33571: Possible indeterminate SSRF, RFI, and LFI attacks since validators accepted leading zeros in IPv4 addresses

`URLValidator`, `validate_ipv4_address()`, and `validate_ipv6_address()` didn't prohibit leading zeros in octal literals. If you used such values you could suffer from indeterminate SSRF, RFI, and LFI attacks.

`validate_ipv4_address()` and `validate_ipv6_address()` validators were not affected on Python 3.9.5+.

Django 3.1.11 release notes

May 13, 2021

Django 3.1.11 fixes a regression in 3.1.9.

Bugfixes

- Fixed a regression in Django 3.1.9 where saving `FileField` would raise a `SuspiciousFileOperation` even when a custom `upload_to` returns a valid file path (#32718).

Django 3.1.10 release notes

May 6, 2021

Django 3.1.10 fixes a security issue in 3.1.9.

CVE-2021-32052: Header injection possibility since `URLValidator` accepted newlines in input on Python 3.9.5+

On Python 3.9.5+, `URLValidator` didn't prohibit newlines and tabs. If you used values with newlines in HTTP response, you could suffer from header injection attacks. Django itself wasn't vulnerable because `HttpResponse` prohibits newlines in HTTP headers.

Moreover, the `URLField` form field which uses `URLValidator` silently removes newlines and tabs on Python 3.9.5+, so the possibility of newlines entering your data only existed if you are using this validator outside of the form fields.

This issue was introduced by the [bpo-43882](#) fix.

Django 3.1.9 release notes

May 4, 2021

Django 3.1.9 fixes a security issue in 3.1.8.

CVE-2021-31542: Potential directory-traversal via uploaded files

`MultiPartParser`, `UploadedFile`, and `FieldFile` allowed directory-traversal via uploaded files with suitably crafted file names.

In order to mitigate this risk, stricter basename and path sanitation is now applied.

Django 3.1.8 release notes

April 6, 2021

Django 3.1.8 fixes a security issue with severity “low” and a bug in 3.1.7.

CVE-2021-28658: Potential directory-traversal via uploaded files

`MultiPartParser` allowed directory-traversal via uploaded files with suitably crafted file names.

Built-in upload handlers were not affected by this vulnerability.

Bugfixes

- Fixed a bug in Django 3.1 where the output was hidden on a test error or failure when using `test --pdb` with the `--buffer` option ([#32560](#)).

Django 3.1.7 release notes

February 19, 2021

Django 3.1.7 fixes a security issue and a bug in 3.1.6.

CVE-2021-23336: Web cache poisoning via `django.utils.http.limited_parse_qs1()`

Django contains a copy of `urllib.parse.parse_qs1()` which was added to backport some security fixes. A further security fix has been issued recently such that `parse_qs1()` no longer allows using `;` as a query parameter separator by default. Django now includes this fix. See [bpo-42967](#) for further details.

Bugfixes

- Fixed a regression in Django 3.1 that caused `RuntimeError` instead of connection errors when using only the 'postgres' database ([#32403](#)).

Django 3.1.6 release notes

February 1, 2021

Django 3.1.6 fixes a security issue with severity “low” and a bug in 3.1.5.

CVE-2021-3281: Potential directory-traversal via `archive.extract()`

The `django.utils.archive.extract()` function, used by `startapp --template` and `startproject --template`, allowed directory-traversal via an archive with absolute paths or relative paths with dot segments.

Bugfixes

- Fixed an admin layout issue in Django 3.1 where changelist filter controls would become squashed ([#32391](#)).

Django 3.1.5 release notes

January 4, 2021

Django 3.1.5 fixes several bugs in 3.1.4.

Bugfixes

- Fixed `__isnull=True` lookup on key transforms for *JSONField* with Oracle and SQLite (#32252).
- Fixed a bug in Django 3.1 that caused a crash when processing middlewares in an async context with a middleware that raises a `MiddlewareNotUsed` exception (#32299).
- Fixed a regression in Django 3.1 that caused the incorrect prefixing of `STATIC_URL` and `MEDIA_URL` settings, by the server-provided value of `SCRIPT_NAME` (or `/` if not set), when set to a URL specifying the protocol but without a top-level domain, e.g. `http://myhost/` (#32304).

Django 3.1.4 release notes

December 1, 2020

Django 3.1.4 fixes several bugs in 3.1.3.

Bugfixes

- Fixed setting the `Content-Length` HTTP header in `AsyncRequestFactory` (#32162).
- Fixed passing extra HTTP headers to `AsyncRequestFactory` request methods (#32159).
- Fixed crash of key transforms for *JSONField* on PostgreSQL when using on a `Subquery()` annotation (#32182).
- Fixed a regression in Django 3.1 that caused a crash of auto-reloader for certain invocations of `runserver` on Windows with Python 3.7 and below (#32202).
- Fixed a regression in Django 3.1 that caused the incorrect grouping by a `Q` object annotation (#32200).
- Fixed a regression in Django 3.1 that caused suppressing connection errors when *JSONField* is used on SQLite (#32224).
- Fixed a crash on SQLite, when `QuerySet.values()/values_list()` contained key transforms for *JSONField* returning non-string primitive values (#32203).

Django 3.1.3 release notes

November 2, 2020

Django 3.1.3 fixes several bugs in 3.1.2 and adds compatibility with Python 3.9.

Bugfixes

- Fixed a regression in Django 3.1.2 that caused the incorrect height of the admin changelist search bar ([#32072](#)).
- Fixed a regression in Django 3.1.2 that caused the incorrect width of the admin changelist search bar on a filtered page ([#32091](#)).
- Fixed displaying Unicode characters in `forms.JSONField` and read-only `models.JSONField` values in the admin ([#32080](#)).
- Fixed a regression in Django 3.1 that caused a crash of `ArrayAgg` and `StringAgg` with `ordering` on key transforms for `JSONField` ([#32096](#)).
- Fixed a regression in Django 3.1 that caused a crash of `__in` lookup when using key transforms for `JSONField` in the lookup value ([#32096](#)).
- Fixed a regression in Django 3.1 that caused a crash of `ExpressionWrapper` with key transforms for `JSONField` ([#32096](#)).
- Fixed a regression in Django 3.1 that caused a migrations crash on PostgreSQL when adding an `ExclusionConstraint` with key transforms for `JSONField` in expressions ([#32096](#)).
- Fixed a regression in Django 3.1 where `ProtectedError.protected_objects` and `RestrictedError.restricted_objects` attributes returned iterators instead of `set` of objects ([#32107](#)).
- Fixed a regression in Django 3.1.2 that caused incorrect form input layout on small screens in the admin change form view ([#32069](#)).
- Fixed a regression in Django 3.1 that invalidated pre-Django 3.1 password reset tokens ([#32130](#)).
- Added support for `asgiref 3.3` ([#32128](#)).
- Fixed a regression in Django 3.1 that caused incorrect textarea layout on medium-sized screens in the admin change form view with the sidebar open ([#32127](#)).
- Fixed a regression in Django 3.0.7 that didn't use `Subquery()` aliases in the `GROUP BY` clause ([#32152](#)).

Django 3.1.2 release notes

October 1, 2020

Django 3.1.2 fixes several bugs in 3.1.1.

Bugfixes

- Fixed a bug in Django 3.1 where `FileField` instances with a callable storage were not correctly deconstructed ([#31941](#)).
- Fixed a regression in Django 3.1 where the `QuerySet.ordered` attribute returned incorrectly `True` for `GROUP BY` queries (e.g. `.annotate().values()`) on models with `Meta.ordering`. A model's `Meta.ordering` doesn't affect such queries ([#31990](#)).
- Fixed a regression in Django 3.1 where a queryset would crash if it contained an aggregation and a `Q` object annotation ([#32007](#)).
- Fixed a bug in Django 3.1 where a test database was not synced during creation when using the `MIGRATE` test database setting ([#32012](#)).
- Fixed a `django.contrib.admin.EmptyFieldListFilter` crash when using on a `GenericRelation` ([#32038](#)).
- Fixed a regression in Django 3.1.1 where the admin changelist filter sidebar would not scroll for a long list of available filters ([#31986](#)).

Django 3.1.1 release notes

September 1, 2020

Django 3.1.1 fixes two security issues and several bugs in 3.1.

CVE-2020-24583: Incorrect permissions on intermediate-level directories on Python 3.7+

On Python 3.7+, `FILE_UPLOAD_DIRECTORY_PERMISSIONS` mode was not applied to intermediate-level directories created in the process of uploading files and to intermediate-level collected static directories when using the `collectstatic` management command.

You should review and manually fix permissions on existing intermediate-level directories.

CVE-2020-24584: Permission escalation in intermediate-level directories of the file system cache on Python 3.7+

On Python 3.7+, the intermediate-level directories of the file system cache had the system's standard umask rather than 0o077 (no group or others permissions).

Bugfixes

- Fixed wrapping of translated action labels in the admin's navigation sidebar for East Asian languages (#31853).
- Fixed wrapping of long model names in the admin's navigation sidebar (#31854).
- Fixed encoding session data while upgrading multiple instances of the same project to Django 3.1 (#31864).
- Adjusted admin's navigation sidebar template to reduce debug logging when rendering (#31865).
- Fixed a data loss possibility in the `select_for_update()`. When using related fields pointing to a proxy model in the `of` argument, the corresponding model was not locked (#31866).
- Fixed a data loss possibility, following a regression in Django 2.0, when copying model instances with a cached fields value (#31863).
- Fixed a regression in Django 3.1 that caused a crash when decoding an invalid session data (#31895).
- Reverted a deprecation in Django 3.1 that caused a crash when passing deprecated keyword arguments to a queryset in `TemplateView.get_context_data()` (#31877).
- Enforced thread sensitivity of the `MiddlewareMixin.process_request()` and `process_response()` hooks when in an async context (#31905).
- Fixed `__in` lookup on key transforms for `JSONField` with MariaDB, MySQL, Oracle, and SQLite (#31936).
- Fixed a regression in Django 3.1 that caused permission errors in `CommonPasswordValidator` and `settings.py` generated by the `startproject` command, when user didn't have permissions to all intermediate directories in a Django installation path (#31912).
- Fixed detecting an async `get_response` callable in various builtin middlewares (#31928).
- Fixed a `QuerySet.order_by()` crash on PostgreSQL when ordering and grouping by `JSONField` with a custom `decoder` (#31956). As a consequence, fetching a `JSONField` with raw SQL now returns a string instead of preloaded data. You will need to explicitly call `json.loads()` in such cases.
- Fixed a `QuerySet.delete()` crash on MySQL, following a performance regression in Django 3.1 on MariaDB 10.3.2+, when filtering against an aggregate function (#31965).
- Fixed a `django.contrib.admin.EmptyFieldListFilter` crash when using on reverse relations (#31952).

- Prevented content overflowing in the admin changelist view when the navigation sidebar is enabled (#31901).

Django 3.1 release notes

August 4, 2020

Welcome to Django 3.1!

These release notes cover the [new features](#), as well as some [backwards incompatible changes](#) you'll want to be aware of when upgrading from Django 3.0 or earlier. We've [dropped some features](#) that have reached the end of their deprecation cycle, and we've [begun the deprecation process for some features](#).

See the [How to upgrade Django to a newer version](#) guide if you're updating an existing project.

Python compatibility

Django 3.1 supports Python 3.6, 3.7, 3.8, and 3.9 (as of 3.1.3). We highly recommend and only officially support the latest release of each series.

What's new in Django 3.1

Asynchronous views and middleware support

Django now supports a fully asynchronous request path, including:

- [Asynchronous views](#)
- [Asynchronous middleware](#)
- [Asynchronous tests and test client](#)

To get started with async views, you need to declare a view using `async def`:

```
async def my_view(request):
    await asyncio.sleep(0.5)
    return HttpResponse("Hello, async world!")
```

All asynchronous features are supported whether you are running under WSGI or ASGI mode. However, there will be performance penalties using async code in WSGI mode. You can read more about the specifics in [Asynchronous support](#) documentation.

You are free to mix async and sync views, middleware, and tests as much as you want. Django will ensure that you always end up with the right execution context. We expect most projects will keep the majority of their views synchronous, and only have a select few running in async mode - but it is entirely your choice.

Django's ORM, cache layer, and other pieces of code that do long-running network calls do not yet support async access. We expect to add support for them in upcoming releases. Async views are ideal, however, if you are doing a lot of API or HTTP calls inside your view, you can now natively do all those HTTP calls in parallel to considerably speed up your view's execution.

Asynchronous support should be entirely backwards-compatible and we have tried to ensure that it has no speed regressions for your existing, synchronous code. It should have no noticeable effect on any existing Django projects.

JSONField for all supported database backends

Django now includes `models.JSONField` and `forms.JSONField` that can be used on all supported database backends. Both fields support the use of custom JSON encoders and decoders. The model field supports the introspection, [lookups](#), and [transforms](#) that were previously PostgreSQL-only:

```
from django.db import models

class ContactInfo(models.Model):
    data = models.JSONField()

ContactInfo.objects.create(
    data={
        "name": "John",
        "cities": ["London", "Cambridge"],
        "pets": {"dogs": ["Rufus", "Meg"]},
    }
)
ContactInfo.objects.filter(
    data__name="John",
    data__pets__has_key="dogs",
    data__cities__contains="London",
).delete()
```

If your project uses `django.contrib.postgres.fields.JSONField`, plus the related form field and transforms, you should adjust to use the new fields, and generate and apply a database migration. For now, the old fields and transforms are left as a reference to the new ones and are [deprecated as of this release](#).

DEFAULT_HASHING_ALGORITHM settings

The new `DEFAULT_HASHING_ALGORITHM` transitional setting allows specifying the default hashing algorithm to use for encoding cookies, password reset tokens in the admin site, user sessions, and signatures created by `django.core.signing.Signer` and `django.core.signing.dumps()`.

Support for SHA-256 was added in Django 3.1. If you are upgrading multiple instances of the same project to Django 3.1, you should set `DEFAULT_HASHING_ALGORITHM` to `'sha1'` during the transition, in order to allow compatibility with the older versions of Django. Note that this requires Django 3.1.1+. Once the transition to 3.1 is complete you can stop overriding `DEFAULT_HASHING_ALGORITHM`.

This setting is deprecated as of this release, because support for tokens, cookies, sessions, and signatures that use SHA-1 algorithm will be removed in Django 4.0.

Minor features

`django.contrib.admin`

- The new `django.contrib.admin.EmptyFieldListFilter` for `ModelAdmin.list_filter` allows filtering on empty values (empty strings and nulls) in the admin changelist view.
- Filters in the right sidebar of the admin changelist view now contain a link to clear all filters.
- The admin now has a sidebar on larger screens for easier navigation. It is enabled by default but can be disabled by using a custom `AdminSite` and setting `AdminSite.enable_nav_sidebar` to `False`.

Rendering the sidebar requires access to the current request in order to set CSS and ARIA role affordances. This requires using `'django.template.context_processors.request'` in the `'context_processors'` option of `OPTIONS`.

- Initially empty `extra` inlines can now be removed, in the same way as dynamically created ones.
- `XRegExp` is upgraded from version 2.0.0 to 3.2.0.
- `jQuery` is upgraded from version 3.4.1 to 3.5.1.
- `Select2` library is upgraded from version 4.0.7 to 4.0.13.

`django.contrib.auth`

- The default iteration count for the PBKDF2 password hasher is increased from 180,000 to 216,000.
- The new `PASSWORD_RESET_TIMEOUT` setting allows defining the number of seconds a password reset link is valid for. This is encouraged instead of the deprecated `PASSWORD_RESET_TIMEOUT_DAYS` setting, which will be removed in Django 4.0.
- The password reset mechanism now uses the SHA-256 hashing algorithm. Support for tokens that use the old hashing algorithm remains until Django 4.0.

- `AbstractBaseUser.get_session_auth_hash()` now uses the SHA-256 hashing algorithm. Support for user sessions that use the old hashing algorithm remains until Django 4.0.

`django.contrib.contenttypes`

- The new `remove_stale_contenttypes --include-stale-apps` option allows removing stale content types from previously installed apps that have been removed from `INSTALLED_APPS`.

`django.contrib.gis`

- `relate` lookup is now supported on MariaDB.
- Added the `LinearRing.is_counterclockwise` property.
- `AsGeoJSON` is now supported on Oracle.
- Added the `AsWKB` and `AsWKT` functions.
- Added support for PostGIS 3 and GDAL 3.

`django.contrib.humanize`

- `intword` template filter now supports negative integers.

`django.contrib.postgres`

- The new `BloomIndex` class allows creating bloom indexes in the database. The new `BloomExtension` migration operation installs the bloom extension to add support for this index.
- `get_FOO_display()` now supports `ArrayField` and `RangeField`.
- The new `rangefield.lower_inc`, `rangefield.lower_inf`, `rangefield.upper_inc`, and `rangefield.upper_inf` lookups allow querying `RangeField` by a bound type.
- `rangefield.contained_by` now supports `SmallAutoField`, `AutoField`, `BigAutoField`, `SmallIntegerField`, and `DecimalField`.
- `SearchQuery` now supports 'websearch' search type on PostgreSQL 11+.
- `SearchQuery.value` now supports query expressions.
- The new `SearchHeadline` class allows highlighting search results.
- `search` lookup now supports query expressions.
- The new `cover_density` parameter of `SearchRank` allows ranking by cover density.
- The new `normalization` parameter of `SearchRank` allows rank normalization.

- The new `ExclusionConstraint.deferrable` attribute allows creating deferrable exclusion constraints.

`django.contrib.sessions`

- The `SESSION_COOKIE_SAMESITE` setting now allows 'None' (string) value to explicitly state that the cookie is sent with all same-site and cross-site requests.

`django.contrib.staticfiles`

- The `STATICFILES_DIRS` setting now supports `pathlib.Path`.

Cache

- The `cache_control()` decorator and `patch_cache_control()` method now support multiple field names in the no-cache directive for the Cache-Control header, according to RFC 7234#section-5.2.2.2.
- `delete()` now returns `True` if the key was successfully deleted, `False` otherwise.

CSRF

- The `CSRF_COOKIE_SAMESITE` setting now allows 'None' (string) value to explicitly state that the cookie is sent with all same-site and cross-site requests.

Email

- The `EMAIL_FILE_PATH` setting, used by the file email backend, now supports `pathlib.Path`.

Error Reporting

- `django.views.debug.SafeExceptionReporterFilter` now filters sensitive values from `request.META` in exception reports.
- The new `SafeExceptionReporterFilter.cleansed_substitute` and `SafeExceptionReporterFilter.hidden_settings` attributes allow customization of sensitive settings and `request.META` filtering in exception reports.
- The technical 404 debug view now respects `DEFAULT_EXCEPTION_REPORTER_FILTER` when applying settings filtering.

- The new `DEFAULT_EXCEPTION_REPORTER` allows providing a `django.views.debug.ExceptionReporter` subclass to customize exception report generation. See [Custom error reports](#) for details.

File Storage

- `FileSystemStorage.save()` method now supports `pathlib.Path`.
- `FileField` and `ImageField` now accept a callable for `storage`. This allows you to modify the used storage at runtime, selecting different storages for different environments, for example.

Forms

- `ModelChoiceIterator`, used by `ModelChoiceField` and `ModelMultipleChoiceField`, now uses `ModelChoiceIteratorValue` that can be used by widgets to access model instances. See [Iterating relationship choices](#) for details.
- `django.forms.DateTimeField` now accepts dates in a subset of ISO 8601 datetime formats, including optional timezone, e.g. `2019-10-10T06:47`, `2019-10-10T06:47:23+04:00`, or `2019-10-10T06:47:23Z`. The timezone will always be retained if provided, with timezone-aware datetimes being returned even when `USE_TZ` is `False`.

Additionally, `DateTimeField` now uses `DATE_INPUT_FORMATS` in addition to `DATETIME_INPUT_FORMATS` when converting a field input to a `datetime` value.

- `MultiWidget.widgets` now accepts a dictionary which allows customizing subwidget `name` attributes.
- The new `BoundField.widget_type` property can be used to dynamically adjust form rendering based upon the widget type.

Internationalization

- The `LANGUAGE_COOKIE_SAMESITE` setting now allows `'None'` (string) value to explicitly state that the cookie is sent with all same-site and cross-site requests.
- Added support and translations for the Algerian Arabic, Igbo, Kyrgyz, Tajik, and Turkmen languages.

Management Commands

- The new `check --database` option allows specifying database aliases for running the database system checks. Previously these checks were enabled for all configured `DATABASES` by passing the database tag to the command.
- The new `migrate --check` option makes the command exit with a non-zero status when unapplied migrations are detected.
- The new `returncode` argument for `CommandError` allows customizing the exit status for management commands.
- The new `dbshell -- ARGUMENTS` option allows passing extra arguments to the command-line client for the database.
- The `flush` and `sqlflush` commands now include SQL to reset sequences on SQLite.

Models

- The new `ExtractIsoWeekDay` function extracts ISO-8601 week days from `DateField` and `DateTimeField`, and the new `iso_week_day` lookup allows querying by an ISO-8601 day of week.
- `QuerySet.explain()` now supports:
 - TREE format on MySQL 8.0.16+,
 - analyze option on MySQL 8.0.18+ and MariaDB.
- Added `PositiveBigIntegerField` which acts much like a `PositiveIntegerField` except that it only allows values under a certain (database-dependent) limit. Values from 0 to 9223372036854775807 are safe in all databases supported by Django.
- The new `RESTRICT` option for `on_delete` argument of `ForeignKey` and `OneToOneField` emulates the behavior of the SQL constraint `ON DELETE RESTRICT`.
- `CheckConstraint.check` now supports boolean expressions.
- The `RelatedManager.add()`, `create()`, and `set()` methods now accept callables as values in the `through_defaults` argument.
- The new `is_dst` parameter of the `QuerySet.dates()` determines the treatment of nonexistent and ambiguous datetimes.
- The new `F` expression `bitxor()` method allows bitwise XOR operation.
- `QuerySet.bulk_create()` now sets the primary key on objects when using MariaDB 10.5+.
- The `DatabaseOperations.sql_flush()` method now generates more efficient SQL on MySQL by using `DELETE` instead of `TRUNCATE` statements for tables which don't require resetting sequences.

- SQLite functions are now marked as `deterministic` on Python 3.8+. This allows using them in check constraints and partial indexes.
- The new `UniqueConstraint.deferrable` attribute allows creating deferrable unique constraints.

Pagination

- `Paginator` can now be iterated over to yield its pages.

Requests and Responses

- If `ALLOWED_HOSTS` is empty and `DEBUG=True`, subdomains of localhost are now allowed in the `Host` header, e.g. `static.localhost`.
- `HttpResponse.set_cookie()` and `HttpResponse.set_signed_cookie()` now allow using `samesite='None'` (string) to explicitly state that the cookie is sent with all same-site and cross-site requests.
- The new `HttpRequest.accepts()` method returns whether the request accepts the given MIME type according to the `Accept` HTTP header.

Security

- The `SECURE_REFERRER_POLICY` setting now defaults to `'same-origin'`. With this configured, `SecurityMiddleware` sets the `Referrer Policy` header to `same-origin` on all responses that do not already have it. This prevents the `Referer` header being sent to other origins. If you need the previous behavior, explicitly set `SECURE_REFERRER_POLICY` to `None`.
- The default algorithm of `django.core.signing.Signer`, `django.core.signing.loads()`, and `django.core.signing.dumps()` is changed to the SHA-256. Support for signatures made with the old SHA-1 algorithm remains until Django 4.0.

Also, the new `algorithm` parameter of the `Signer` allows customizing the hashing algorithm.

Templates

- The renamed `translate` and `blocktranslate` template tags are introduced for internationalization in template code. The older `trans` and `blocktrans` template tags aliases continue to work, and will be retained for the foreseeable future.
- The `include` template tag now accepts iterables of template names.

Tests

- `SimpleTestCase` now implements the `debug()` method to allow running a test without collecting the result and catching exceptions. This can be used to support running tests under a debugger.
- The new `MIGRATE` test database setting allows disabling of migrations during a test database creation.
- Django test runner now supports a `test --buffer` option to discard output for passing tests.
- `DiscoverRunner` now skips running the system checks on databases not referenced by tests.
- `TransactionTestCase` teardown is now faster on MySQL due to `flush` command improvements. As a side effect the latter doesn't automatically reset sequences on teardown anymore. Enable `TransactionTestCase.reset_sequences` if your tests require this feature.

URLs

- `Path` converters can now raise `ValueError` in `to_url()` to indicate no match when reversing URLs.

Utilities

- `filepath_to_uri()` now supports `pathlib.Path`.
- `parse_duration()` now supports comma separators for decimal fractions in the ISO 8601 format.
- `parse_datetime()`, `parse_duration()`, and `parse_time()` now support comma separators for milliseconds.

Miscellaneous

- The SQLite backend now supports `pathlib.Path` for the `NAME` setting.
- The `settings.py` generated by the `startproject` command now uses `pathlib.Path` instead of `os.path` for building filesystem paths.
- The `TIME_ZONE` setting is now allowed on databases that support time zones.

Backwards incompatible changes in 3.1

Database backend API

This section describes changes that may be needed in third-party database backends.

- `DatabaseOperations.fetch_returned_insert_columns()` now requires an additional `returning_params` argument.

- `connection.timezone` property is now 'UTC' by default, or the `TIME_ZONE` when `USE_TZ` is True on databases that support time zones. Previously, it was None on databases that support time zones.
- `connection._nodb_connection` property is changed to the `connection._nodb_cursor()` method and now returns a context manager that yields a cursor and automatically closes the cursor and connection upon exiting the `with` statement.
- `DatabaseClient.runshell()` now requires an additional `parameters` argument as a list of extra arguments to pass on to the command-line client.
- The `sequences` positional argument of `DatabaseOperations.sql_flush()` is replaced by the boolean keyword-only argument `reset_sequences`. If True, the sequences of the truncated tables will be reset.
- The `allow_cascade` argument of `DatabaseOperations.sql_flush()` is now a keyword-only argument.
- The `using` positional argument of `DatabaseOperations.execute_sql_flush()` is removed. The method now uses the database of the called instance.
- Third-party database backends must implement support for `JSONField` or set `DatabaseFeatures.supports_json_field` to False. If storing primitives is not supported, set `DatabaseFeatures.supports_primitives_in_json_field` to False. If there is a true datatype for JSON, set `DatabaseFeatures.has_native_json_field` to True. If `jsonfield.contains` and `jsonfield.contained_by` are not supported, set `DatabaseFeatures.supports_json_field_contains` to False.
- Third party database backends must implement introspection for `JSONField` or set `can_introspect_json_field` to False.

Dropped support for MariaDB 10.1

Upstream support for MariaDB 10.1 ends in October 2020. Django 3.1 supports MariaDB 10.2 and higher.

`contrib.admin` browser support

The admin no longer supports the legacy Internet Explorer browser. See [the admin FAQ](#) for details on supported browsers.

`AbstractUser.first_name` max_length increased to 150

A migration for `django.contrib.auth.models.User.first_name` is included. If you have a custom user model inheriting from `AbstractUser`, you'll need to generate and apply a database migration for your user model.

If you want to preserve the 30 character limit for first names, use a custom form:

```
from django import forms
from django.contrib.auth.forms import UserChangeForm

class MyUserChangeForm(UserChangeForm):
    first_name = forms.CharField(max_length=30, required=False)
```

If you wish to keep this restriction in the admin when editing users, set `UserAdmin.form` to use this form:

```
from django.contrib.auth.admin import UserAdmin
from django.contrib.auth.models import User

class MyUserAdmin(UserAdmin):
    form = MyUserChangeForm

admin.site.unregister(User)
admin.site.register(User, MyUserAdmin)
```

Miscellaneous

- The cache keys used by `cache` and generated by `make_template_fragment_key()` are different from the keys generated by older versions of Django. After upgrading to Django 3.1, the first request to any previously cached template fragment will be a cache miss.
- The logic behind the decision to return a redirection fallback or a 204 HTTP response from the `set_language()` view is now based on the Accept HTTP header instead of the X-Requested-With HTTP header presence.
- The compatibility imports of `django.core.exceptions.EmptyResultSet` in `django.db.models.query`, `django.db.models.sql`, and `django.db.models.sql.datastructures` are removed.
- The compatibility import of `django.core.exceptions.FieldDoesNotExist` in `django.db.models.fields` is removed.
- The compatibility imports of `django.forms.utils.pretty_name()` and `django.forms.boundfield.BoundField` in `django.forms.forms` are removed.
- The compatibility imports of `Context`, `ContextPopException`, and `RequestContext` in `django.template.base` are removed.
- The compatibility import of `django.contrib.admin.helpers.ACTION_CHECKBOX_NAME` in `django.contrib.admin` is removed.
- The `STATIC_URL` and `MEDIA_URL` settings set to relative paths are now prefixed by the server-provided

value of `SCRIPT_NAME` (or `/` if not set). This change should not affect settings set to valid URLs or absolute paths.

- `ConditionalGetMiddleware` no longer adds the ETag header to responses with an empty `content`.
- `django.utils.decorators.classproperty()` decorator is made public and moved to `django.utils.functional.classproperty()`.
- `floatformat` template filter now outputs (positive) 0 for negative numbers which round to zero.
- `Meta.ordering` and `Meta.unique_together` options on models in `django.contrib` modules that were formerly tuples are now lists.
- The admin calendar widget now handles two-digit years according to the Open Group Specification, i.e. values between 69 and 99 are mapped to the previous century, and values between 0 and 68 are mapped to the current century.
- Date-only formats are removed from the default list for `DATETIME_INPUT_FORMATS`.
- The `FileInput` widget no longer renders with the `required` HTML attribute when initial data exists.
- The undocumented `django.views.debug.ExceptionReporterFilter` class is removed. As per the [Custom error reports](#) documentation, classes to be used with `DEFAULT_EXCEPTION_REPORTER_FILTER` need to inherit from `django.views.debug.SafeExceptionReporterFilter`.
- The cache timeout set by `cache_page()` decorator now takes precedence over the `max-age` directive from the `Cache-Control` header.
- Providing a non-local remote field in the `ForeignKey.to_field` argument now raises `FieldError`.
- `SECURE_REFERRER_POLICY` now defaults to 'same-origin'. See the [What's New Security](#) section above for more details.
- `check` management command now runs the database system checks only for database aliases specified using `check --database` option.
- `migrate` management command now runs the database system checks only for a database to migrate.
- The admin CSS classes `row1` and `row2` are removed in favor of `:nth-child(odd)` and `:nth-child(even)` pseudo-classes.
- The `make_password()` function now requires its argument to be a string or bytes. Other types should be explicitly cast to one of these.
- The undocumented `version` parameter to the `AsKML` function is removed.
- `JSON` and `YAML` serializers, used by `dumpdata`, now dump all data with Unicode by default. If you need the previous behavior, pass `ensure_ascii=True` to JSON serializer, or `allow_unicode=False` to YAML serializer.
- The auto-reloader no longer monitors changes in built-in Django translation files.
- The minimum supported version of `mysqlclient` is increased from 1.3.13 to 1.4.0.

- The undocumented `django.contrib.postgres.forms.InvalidJSONInput` and `django.contrib.postgres.forms.JSONString` are moved to `django.forms.fields`.
- The undocumented `django.contrib.postgres.fields.jsonb.JsonAdapter` class is removed.
- The `{% localize off %}` tag and `unlocalize` filter no longer respect `DECIMAL_SEPARATOR` setting.
- The minimum supported version of `asgiref` is increased from 3.2 to 3.2.10.
- The `Media` class now renders `<script>` tags without the `type` attribute to follow WHATWG recommendations.
- `ModelChoiceIterator`, used by `ModelChoiceField` and `ModelMultipleChoiceField`, now yields 2-tuple choices containing `ModelChoiceIteratorValue` instances as the first value element in each choice. In most cases this proxies transparently, but if you need the field value itself, use the `ModelChoiceIteratorValue.value` attribute instead.

Features deprecated in 3.1

PostgreSQL JSONField

`django.contrib.postgres.fields.JSONField` and `django.contrib.postgres.forms.JSONField` are deprecated in favor of `models.JSONField` and `forms.JSONField`.

The undocumented `django.contrib.postgres.fields.jsonb.KeyTransform` and `django.contrib.postgres.fields.jsonb.KeyTextTransform` are also deprecated in favor of the transforms in `django.db.models.fields.json`.

The new JSONFields, `KeyTransform`, and `KeyTextTransform` can be used on all supported database backends.

Miscellaneous

- `PASSWORD_RESET_TIMEOUT_DAYS` setting is deprecated in favor of `PASSWORD_RESET_TIMEOUT`.
- The undocumented usage of the `isnull` lookup with non-boolean values as the right-hand side is deprecated, use `True` or `False` instead.
- The barely documented `django.db.models.query_utils.InvalidQuery` exception class is deprecated in favor of `FieldDoesNotExist` and `FieldError`.
- The `django-admin.py` entry point is deprecated in favor of `django-admin`.
- The `HttpRequest.is_ajax()` method is deprecated as it relied on a jQuery-specific way of signifying AJAX calls, while current usage tends to use the JavaScript `Fetch API`. Depending on your use case, you can either write your own AJAX detection method, or use the new `HttpRequest.accepts()` method if your code depends on the client Accept HTTP header.

If you are writing your own AJAX detection method, `request.is_ajax()` can be reproduced exactly as `request.headers.get('x-requested-with') == 'XMLHttpRequest'`.

- Passing `None` as the first argument to `django.utils.deprecation.MiddlewareMixin.__init__()` is deprecated.
- The encoding format of cookies values used by `CookieStorage` is different from the format generated by older versions of Django. Support for the old format remains until Django 4.0.
- The encoding format of sessions is different from the format generated by older versions of Django. Support for the old format remains until Django 4.0.
- The purely documentation `providing_args` argument for `Signal` is deprecated. If you rely on this argument as documentation, you can move the text to a code comment or docstring.
- Calling `django.utils.crypto.get_random_string()` without a `length` argument is deprecated.
- The `list` message for `ModelMultipleChoiceField` is deprecated in favor of `invalid_list`.
- Passing raw column aliases to `QuerySet.order_by()` is deprecated. The same result can be achieved by passing aliases in a `RawSQL` instead beforehand.
- The `NullBooleanField` model field is deprecated in favor of `BooleanField(null=True)`.
- `django.conf.urls.url()` alias of `django.urls.re_path()` is deprecated.
- The `{% ifequal %}` and `{% ifnotequal %}` template tags are deprecated in favor of `{% if %}`. `{% if %}` covers all use cases, but if you need to continue using these tags, they can be extracted from Django to a module and included as a built-in tag in the `'builtins'` option in `OPTIONS`.
- `DEFAULT_HASHING_ALGORITHM` transitional setting is deprecated.

Features removed in 3.1

These features have reached the end of their deprecation cycle and are removed in Django 3.1.

See [Features deprecated in 2.2](#) for details on these changes, including how to remove usage of these features.

- `django.utils.timezone.FixedOffset` is removed.
- `django.core.paginator.QuerySetPaginator` is removed.
- A model's `Meta.ordering` doesn't affect `GROUP BY` queries.
- `django.contrib.postgres.fields.FloatRangeField` and `django.contrib.postgres.forms.FloatRangeField` are removed.
- The `FILE_CHARSET` setting is removed.
- `django.contrib.staticfiles.storage.CachedStaticFilesStorage` is removed.
- The `RemoteUserBackend.configure_user()` method requires `request` as the first positional argument.

- Support for `SimpleTestCase.allow_database_queries` and `TransactionTestCase.multi_db` is removed.

9.1.6 3.0 release

Django 3.0.14 release notes

April 6, 2021

Django 3.0.14 fixes a security issue with severity “low” in 3.0.13.

CVE-2021-28658: Potential directory-traversal via uploaded files

`MultiPartParser` allowed directory-traversal via uploaded files with suitably crafted file names.

Built-in upload handlers were not affected by this vulnerability.

Django 3.0.13 release notes

February 19, 2021

Django 3.0.13 fixes a security issue in 3.0.12.

CVE-2021-23336: Web cache poisoning via `django.utils.http.limited_parse_qs()`

Django contains a copy of `urllib.parse.parse_qs()` which was added to backport some security fixes. A further security fix has been issued recently such that `parse_qs()` no longer allows using `;` as a query parameter separator by default. Django now includes this fix. See [bpo-42967](#) for further details.

Django 3.0.12 release notes

February 1, 2021

Django 3.0.12 fixes a security issue with severity “low” in 3.0.11.

CVE-2021-3281: Potential directory-traversal via `archive.extract()`

The `django.utils.archive.extract()` function, used by `startapp --template` and `startproject --template`, allowed directory-traversal via an archive with absolute paths or relative paths with dot segments.

Django 3.0.11 release notes

November 2, 2020

Django 3.0.11 fixes a regression in 3.0.7 and adds compatibility with Python 3.9.

Bugfixes

- Fixed a regression in Django 3.0.7 that didn't use `Subquery()` aliases in the `GROUP BY` clause ([#32152](#)).

Django 3.0.10 release notes

September 1, 2020

Django 3.0.10 fixes two security issues and two data loss bugs in 3.0.9.

CVE-2020-24583: Incorrect permissions on intermediate-level directories on Python 3.7+

On Python 3.7+, `FILE_UPLOAD_DIRECTORY_PERMISSIONS` mode was not applied to intermediate-level directories created in the process of uploading files and to intermediate-level collected static directories when using the `collectstatic` management command.

You should review and manually fix permissions on existing intermediate-level directories.

CVE-2020-24584: Permission escalation in intermediate-level directories of the file system cache on Python 3.7+

On Python 3.7+, the intermediate-level directories of the file system cache had the system's standard umask rather than `0o077` (no group or others permissions).

Bugfixes

- Fixed a data loss possibility in the `select_for_update()`. When using related fields pointing to a proxy model in the `of` argument, the corresponding model was not locked ([#31866](#)).
- Fixed a data loss possibility, following a regression in Django 2.0, when copying model instances with a cached fields value ([#31863](#)).

Django 3.0.9 release notes

August 3, 2020

Django 3.0.9 fixes several bugs in 3.0.8.

Bugfixes

- Allowed setting the `SameSite` cookie flag in `HttpResponse.delete_cookie()` (#31790).
- Fixed crash when sending emails to addresses with display names longer than 75 chars on Python 3.6.11+, 3.7.8+, and 3.8.4+ (#31784).

Django 3.0.8 release notes

July 1, 2020

Django 3.0.8 fixes several bugs in 3.0.7.

Bugfixes

- Fixed messages of `InvalidCacheKey` exceptions and `CacheKeyWarning` warnings raised by cache key validation (#31654).
- Fixed a regression in Django 3.0.7 that caused a queryset crash when grouping by a many-to-one relationship (#31660).
- Reallowed, following a regression in Django 3.0, non-expressions having a `filterable` attribute to be used as the right-hand side in queryset filters (#31664).
- Fixed a regression in Django 3.0.2 that caused a migration crash on PostgreSQL when adding a foreign key to a model with a namespaced `db_table` (#31735).
- Added compatibility for `cx_Oracle` 8 (#31751).

Django 3.0.7 release notes

June 3, 2020

Django 3.0.7 fixes two security issues and several bugs in 3.0.6.

CVE-2020-13254: Potential data leakage via malformed memcached keys

In cases where a memcached backend does not perform key validation, passing malformed cache keys could result in a key collision, and potential data leakage. In order to avoid this vulnerability, key validation is added to the memcached cache backends.

CVE-2020-13596: Possible XSS via admin `ForeignKeyRawIdWidget`

Query parameters for the admin `ForeignKeyRawIdWidget` were not properly URL encoded, posing an XSS attack vector. `ForeignKeyRawIdWidget` now ensures query parameters are correctly URL encoded.

Bugfixes

- Fixed a regression in Django 3.0 by restoring the ability to use field lookups in `Meta.ordering` (#31538).
- Fixed a regression in Django 3.0 where `QuerySet.values()` and `values_list()` crashed if a queryset contained an aggregation and a subquery annotation (#31566).
- Fixed a regression in Django 3.0 where aggregates used wrong annotations when a queryset has multiple subqueries annotations (#31568).
- Fixed a regression in Django 3.0 where `QuerySet.values()` and `values_list()` crashed if a queryset contained an aggregation and an `Exists()` annotation on Oracle (#31584).
- Fixed a regression in Django 3.0 where all resolved `Subquery()` expressions were considered equal (#31607).
- Fixed a regression in Django 3.0.5 that affected translation loading for apps providing translations for territorial language variants as well as a generic language, where the project has different plural equations for the language (#31570).
- Tracking a jQuery security release, upgraded the version of jQuery used by the admin from 3.4.1 to 3.5.1.

Django 3.0.6 release notes

May 4, 2020

Django 3.0.6 fixes a bug in 3.0.5.

Bugfixes

- Fixed a regression in Django 3.0 that caused a crash when filtering a `Subquery()` annotation of a query-set containing a single related field against a `SimpleLazyObject` ([#31420](#)).

Django 3.0.5 release notes

April 1, 2020

Django 3.0.5 fixes several bugs in 3.0.4.

Bugfixes

- Added the ability to handle `.po` files containing different plural equations for the same language ([#30439](#)).
- Fixed a regression in Django 3.0 where `QuerySet.values()` and `values_list()` crashed if a queryset contained an aggregation and `Subquery()` annotation that collides with a field name ([#31377](#)).

Django 3.0.4 release notes

March 4, 2020

Django 3.0.4 fixes a security issue and several bugs in 3.0.3.

CVE-2020-9402: Potential SQL injection via `tolerance` parameter in GIS functions and aggregates on Oracle

GIS functions and aggregates on Oracle were subject to SQL injection, using a suitably crafted `tolerance`.

Bugfixes

- Fixed a data loss possibility when using caching from async code ([#31253](#)).
- Fixed a regression in Django 3.0 that caused a file response using a temporary file to be closed incorrectly ([#31240](#)).
- Fixed a data loss possibility in the `select_for_update()`. When using related fields or parent link fields with [Multi-table inheritance](#) in the `of` argument, the corresponding models were not locked ([#31246](#)).
- Fixed a regression in Django 3.0 that caused misplacing parameters in logged SQL queries on Oracle ([#31271](#)).
- Fixed a regression in Django 3.0.3 that caused misplacing parameters of SQL queries when subtracting `DateTimeField` or `DateTimeField` expressions on MySQL ([#31312](#)).

- Fixed a regression in Django 3.0 that didn't include subqueries spanning multivalued relations in the `GROUP BY` clause (#31150).

Django 3.0.3 release notes

February 3, 2020

Django 3.0.3 fixes a security issue and several bugs in 3.0.2.

CVE-2020-7471: Potential SQL injection via `StringAgg(delimiter)`

StringAgg aggregation function was subject to SQL injection, using a suitably crafted `delimiter`.

Bugfixes

- Fixed a regression in Django 3.0 that caused a crash when subtracting `DateField`, `DateTimeField`, or `TimeField` from a `Subquery()` annotation (#31133).
- Fixed a regression in Django 3.0 where `QuerySet.values()` and `values_list()` crashed if a queryset contained an aggregation and `Exists()` annotation (#31136).
- Relaxed the system check added in Django 3.0 to reallow use of a sublanguage in the `LANGUAGE_CODE` setting, when a base language is available in Django but the sublanguage is not (#31141).
- Added support for using enumeration types `TextChoices`, `IntegerChoices`, and `Choices` in templates (#31154).
- Fixed a system check to ensure the `max_length` attribute fits the longest choice, when a named group contains only non-string values (#31155).
- Fixed a regression in Django 2.2 that caused a crash of *ArrayAgg* and *StringAgg* with `filter` argument when used in a `Subquery` (#31097).
- Fixed a regression in Django 2.2.7 that caused *get_FOO_display()* to work incorrectly when overriding inherited choices (#31124).
- Fixed a regression in Django 3.0 that caused a crash of `QuerySet.prefetch_related()` for `GenericForeignKey` with a custom `ContentType` foreign key (#31190).

Django 3.0.2 release notes

January 2, 2020

Django 3.0.2 fixes several bugs in 3.0.1.

Bugfixes

- Fixed a regression in Django 3.0 that didn't include columns referenced by a `Subquery()` in the `GROUP BY` clause ([#31094](#)).
- Fixed a regression in Django 3.0 where `QuerySet.exists()` crashed if a queryset contained an aggregation over a `Subquery()` ([#31109](#)).
- Fixed a regression in Django 3.0 that caused a migration crash on PostgreSQL 10+ when adding a foreign key and changing data in the same migration ([#31106](#)).
- Fixed a regression in Django 3.0 where loading fixtures crashed for models defining a *default* for the primary key ([#31071](#)).

Django 3.0.1 release notes

December 18, 2019

Django 3.0.1 fixes a security issue and several bugs in 3.0.

CVE-2019-19844: Potential account hijack via password reset form

By submitting a suitably crafted email address making use of Unicode characters, that compared equal to an existing user email when lower-cased for comparison, an attacker could be sent a password reset token for the matched account.

In order to avoid this vulnerability, password reset requests now compare the submitted email using the stricter, recommended algorithm for case-insensitive comparison of two identifiers from [Unicode Technical Report 36, section 2.11.2\(B\)\(2\)](#). Upon a match, the email containing the reset token will be sent to the email address on record rather than the submitted address.

Bugfixes

- Fixed a regression in Django 3.0 by restoring the ability to use Django inside Jupyter and other environments that force an async context, by adding an option to disable [Async safety](#) mechanism with `DJANGO_ALLOW_ASYNC_UNSAFE` environment variable ([#31056](#)).
- Fixed a regression in Django 3.0 where `RegexPattern`, used by `re_path()`, returned positional arguments to be passed to the view when all optional named groups were missing ([#31061](#)).
- Reallowed, following a regression in Django 3.0, *Window* expressions to be used in conditions outside of queryset filters, e.g. in *When* conditions ([#31060](#)).
- Fixed a data loss possibility in *SplitArrayField*. When using with `ArrayField(BooleanField())`, all values after the first `True` value were marked as checked instead of preserving passed values ([#31073](#)).

Django 3.0 release notes

December 2, 2019

Welcome to Django 3.0!

These release notes cover the [new features](#), as well as some [backwards incompatible changes](#) you'll want to be aware of when upgrading from Django 2.2 or earlier. We've [dropped some features](#) that have reached the end of their deprecation cycle, and we've [begun the deprecation process](#) for some features.

See the [How to upgrade Django to a newer version](#) guide if you're updating an existing project.

Python compatibility

Django 3.0 supports Python 3.6, 3.7, 3.8, and 3.9 (as of 3.0.11). We highly recommend and only officially support the latest release of each series.

The Django 2.2.x series is the last to support Python 3.5.

Third-party library support for older version of Django

Following the release of Django 3.0, we suggest that third-party app authors drop support for all versions of Django prior to 2.2. At that time, you should be able to run your package's tests using `python -Wd` so that deprecation warnings appear. After making the deprecation warning fixes, your app should be compatible with Django 3.0.

What's new in Django 3.0

MariaDB support

Django now officially supports [MariaDB](#) 10.1 and higher. See [MariaDB notes](#) for more details.

ASGI support

Django 3.0 begins our journey to making Django fully async-capable by providing support for running as an [ASGI](#) application.

This is in addition to our existing WSGI support. Django intends to support both for the foreseeable future. Async features will only be available to applications that run under ASGI, however.

At this stage async support only applies to the outer ASGI application. Internally everything remains synchronous. Asynchronous middleware, views, etc. are not yet supported. You can, however, use ASGI middleware around Django's application, allowing you to combine Django with other ASGI frameworks.

There is no need to switch your applications over unless you want to start experimenting with asynchronous code, but we have [documentation on deploying with ASGI](#) if you want to learn more.

Note that as a side-effect of this change, Django is now aware of asynchronous event loops and will block you calling code marked as “async unsafe” - such as ORM operations - from an asynchronous context. If you were using Django from async code before, this may trigger if you were doing it incorrectly. If you see a `SynchronousOnlyOperation` error, then closely examine your code and move any database operations to be in a synchronous child thread.

Exclusion constraints on PostgreSQL

The new [`ExclusionConstraint`](#) class enable adding exclusion constraints on PostgreSQL. Constraints are added to models using the [`Meta.constraints`](#) option.

Filter expressions

Expressions that output [`BooleanField`](#) may now be used directly in `QuerySet` filters, without having to first annotate and then filter against the annotation.

Enumerations for model field choices

Custom enumeration types `TextChoices`, `IntegerChoices`, and `Choices` are now available as a way to define *Field.choices*. `TextChoices` and `IntegerChoices` types are provided for text and integer fields. The `Choices` class allows defining a compatible enumeration for other concrete data types. These custom enumeration types support human-readable labels that can be translated and accessed via a property on the enumeration or its members. See [Enumeration types](#) for more details and examples.

Minor features

`django.contrib.admin`

- Added support for the `admin_order_field` attribute on properties in *ModelAdmin.list_display*.
- The new *ModelAdmin.get_inlines()* method allows specifying the inlines based on the request or model instance.
- Select2 library is upgraded from version 4.0.3 to 4.0.7.
- jQuery is upgraded from version 3.3.1 to 3.4.1.

`django.contrib.auth`

- The new `reset_url_token` attribute in *PasswordResetConfirmView* allows specifying a token parameter displayed as a component of password reset URLs.
- Added *BaseBackend* class to ease customization of authentication backends.
- Added *get_user_permissions()* method to mirror the existing *get_group_permissions()* method.
- Added HTML `autocomplete` attribute to widgets of username, email, and password fields in *django.contrib.auth.forms* for better interaction with browser password managers.
- *createsuperuser* now falls back to environment variables for password and required fields, when a corresponding command line argument isn't provided in non-interactive mode.
- *REQUIRED_FIELDS* now supports *ManyToManyFields*.
- The new *UserManager.with_perm()* method returns users that have the specified permission.
- The default iteration count for the PBKDF2 password hasher is increased from 150,000 to 180,000.

`django.contrib.gis`

- Allowed MySQL spatial lookup functions to operate on real geometries. Previous support was limited to bounding boxes.
- Added the *GeometryDistance* function, supported on PostGIS.
- Added support for the furlong unit in *Distance*.
- The *GEOIP_PATH* setting now supports `pathlib.Path`.
- The *GeoIP2* class now accepts `pathlib.Path` path.

`django.contrib.postgres`

- The new *RangeOperators* helps to avoid typos in SQL operators that can be used together with *RangeField*.
- The new *RangeBoundary* expression represents the range boundaries.
- The new *AddIndexConcurrently* and *RemoveIndexConcurrently* classes allow creating and dropping indexes CONCURRENTLY on PostgreSQL.

`django.contrib.sessions`

- The new *get_session_cookie_age()* method allows dynamically specifying the session cookie age.

`django.contrib.syndication`

- Added the language class attribute to the *django.contrib.syndication.views.Feed* to customize a feed language. The default value is *get_language()* instead of *LANGUAGE_CODE*.

Cache

- *add_never_cache_headers()* and *never_cache()* now add the `private` directive to Cache-Control headers.

File Storage

- The new `Storage.get_alternative_name()` method allows customizing the algorithm for generating filenames if a file with the uploaded name already exists.

Forms

- Formsets may control the widget used when ordering forms via `can_order` by setting the `ordering_widget` attribute or overriding `get_ordering_widget()`.

Internationalization

- Added the `LANGUAGE_COOKIE_HTTPONLY`, `LANGUAGE_COOKIE_SAMESITE`, and `LANGUAGE_COOKIE_SECURE` settings to set the `HttpOnly`, `SameSite`, and `Secure` flags on language cookies. The default values of these settings preserve the previous behavior.
- Added support and translations for the Uzbek language.

Logging

- The new `reporter_class` parameter of `AdminEmailHandler` allows providing an `django.views.debug.ExceptionReporter` subclass to customize the traceback text sent to site `ADMINS` when `DEBUG` is `False`.

Management Commands

- The new `compilemessages --ignore` option allows ignoring specific directories when searching for `.po` files to compile.
- `showmigrations --list` now shows the applied datetimes when `--verbosity` is 2 and above.
- On PostgreSQL, `dbshell` now supports client-side TLS certificates.
- `inspectdb` now introspects `OneToOneField` when a foreign key has a unique or primary key constraint.
- The new `--skip-checks` option skips running system checks prior to running the command.
- The `startapp --template` and `startproject --template` options now support templates stored in XZ archives (`.tar.xz`, `.txz`) and LZMA archives (`.tar.lzma`, `.tlz`).

Models

- Added hash database functions *MD5*, *SHA1*, *SHA224*, *SHA256*, *SHA384*, and *SHA512*.
- Added the *Sign* database function.
- The new *is_dst* parameter of the *Trunc* database functions determines the treatment of nonexistent and ambiguous datetimes.
- `connection.queries` now shows `COPY ... TO` statements on PostgreSQL.
- *FilePathField* now accepts a callable for `path`.
- Allowed symmetrical intermediate table for self-referential *ManyToManyField*.
- The `name` attributes of *CheckConstraint*, *UniqueConstraint*, and *Index* now support app label and class interpolation using the `'%(app_label)s'` and `'%(class)s'` placeholders.
- The new *Field.descriptor_class* attribute allows model fields to customize the get and set behavior by overriding their `descriptors`.
- *Avg* and *Sum* now support the `distinct` argument.
- Added *SmallAutoField* which acts much like an *AutoField* except that it only allows values under a certain (database-dependent) limit. Values from 1 to 32767 are safe in all databases supported by Django.
- *AutoField*, *BigAutoField*, and *SmallAutoField* now inherit from *IntegerField*, *BigIntegerField* and *SmallIntegerField* respectively. System checks and validators are now also properly inherited.
- *FileField.upload_to* now supports `pathlib.Path`.
- *CheckConstraint* is now supported on MySQL 8.0.16+.
- The new `allows_group_by_selected_pks_on_model()` method of `django.db.backends.base.BaseDatabaseFeatures` allows optimization of `GROUP BY` clauses to require only the selected models' primary keys. By default, it's supported only for managed models on PostgreSQL.

To enable the `GROUP BY` primary key-only optimization for unmanaged models, you have to subclass the PostgreSQL database engine, overriding the `features` class `allows_group_by_selected_pks_on_model()` method as you require. See [Subclassing the built-in database backends](#) for an example.

Requests and Responses

- Allowed `HttpResponse` to be initialized with `memoryview` content.
- For use in, for example, Django templates, `HttpRequest.headers` now allows lookups using underscores (e.g. `user_agent`) in place of hyphens.

Security

- `X_FRAME_OPTIONS` now defaults to 'DENY'. In older versions, the `X_FRAME_OPTIONS` setting defaults to 'SAMEORIGIN'. If your site uses frames of itself, you will need to explicitly set `X_FRAME_OPTIONS = 'SAMEORIGIN'` for them to continue working.
- `SECURE_CONTENT_TYPE_NOSNIFF` now defaults to `True`. With this enabled, `SecurityMiddleware` sets the X-Content-Type-Options: nosniff header on all responses that do not already have it.
- `SecurityMiddleware` can now send the Referrer-Policy header.

Tests

- The new test `Client` argument `raise_request_exception` allows controlling whether or not exceptions raised during the request should also be raised in the test. The value defaults to `True` for backwards compatibility. If it is `False` and an exception occurs, the test client will return a 500 response with the attribute `exc_info`, a tuple providing information of the exception that occurred.
- Tests and test cases to run can be selected by test name pattern using the new `test -k` option.
- HTML comparison, as used by `assertHTMLEqual()`, now treats text, character references, and entity references that refer to the same character as equivalent.
- Django test runner now supports headless mode for selenium tests on supported browsers. Add the `--headless` option to enable this mode.
- Django test runner now supports `--start-at` and `--start-after` options to run tests starting from a specific top-level module.
- Django test runner now supports a `--pdb` option to spawn a debugger at each error or failure.

Backwards incompatible changes in 3.0

`Model.save()` when providing a default for the primary key

`Model.save()` no longer attempts to find a row when saving a new `Model` instance and a default value for the primary key is provided, and always performs a single `INSERT` query. In older Django versions, `Model.save()` performed either an `INSERT` or an `UPDATE` based on whether or not the row exists.

This makes calling `Model.save()` while providing a default primary key value equivalent to passing `force_insert=True` to `model.save()`. Attempts to use a new `Model` instance to update an existing row will result in an `IntegrityError`.

In order to update an existing model for a specific primary key value, use the `update_or_create()` method or `QuerySet.filter(pk=...).update(...)` instead. For example:

```
>>> MyModel.objects.update_or_create(pk=existing_pk, defaults={"name": "new name"})
>>> MyModel.objects.filter(pk=existing_pk).update(name="new name")
```

Database backend API

This section describes changes that may be needed in third-party database backends.

- The second argument of `DatabaseIntrospection.get_geometry_type()` is now the row description instead of the column name.
- `DatabaseIntrospection.get_field_type()` may no longer return tuples.
- If the database can create foreign keys in the same SQL statement that adds a field, add `SchemaEditor.sql_create_column_inline_fk` with the appropriate SQL; otherwise, set `DatabaseFeatures.can_create_inline_fk = False`.
- `DatabaseFeatures.can_return_id_from_insert` and `can_return_ids_from_bulk_insert` are renamed to `can_return_columns_from_insert` and `can_return_rows_from_bulk_insert`.
- Database functions now handle `datetime.timezone` formats when created using `datetime.timedelta` instances (e.g. `timezone(timedelta(hours=5))`, which would output `'UTC+05:00'`). Third-party backends should handle this format when preparing `DateTimeField` in `datetime_cast_date_sql()`, `datetime_extract_sql()`, etc.
- Entries for `AutoField`, `BigAutoField`, and `SmallAutoField` are added to `DatabaseOperations.integer_field_ranges` to support the integer range validators on these field types. Third-party backends may need to customize the default entries.
- `DatabaseOperations.fetch_returned_insert_id()` is replaced by `fetch_returned_insert_columns()` which returns a list of values returned by the `INSERT ... RETURNING` statement, instead of a single value.

- `DatabaseOperations.return_insert_id()` is replaced by `return_insert_columns()` that accepts a `fields` argument, which is an iterable of fields to be returned after insert. Usually this is only the auto-generated primary key.

`django.contrib.admin`

- Admin's model history change messages now prefers more readable field labels instead of field names.

`django.contrib.gis`

- Support for PostGIS 2.1 is removed.
- Support for SpatiaLite 4.1 and 4.2 is removed.
- Support for GDAL 1.11 and GEOS 3.4 is removed.

Dropped support for PostgreSQL 9.4

Upstream support for PostgreSQL 9.4 ends in December 2019. Django 3.0 supports PostgreSQL 9.5 and higher.

Dropped support for Oracle 12.1

Upstream support for Oracle 12.1 ends in July 2021. Django 2.2 will be supported until April 2022. Django 3.0 officially supports Oracle 12.2 and 18c.

Removed private Python 2 compatibility APIs

While Python 2 support was removed in Django 2.0, some private APIs weren't removed from Django so that third party apps could continue using them until the Python 2 end-of-life.

Since we expect apps to drop Python 2 compatibility when adding support for Django 3.0, we're removing these APIs at this time.

- `django.test.utils.str_prefix()` - Strings don't have 'u' prefixes in Python 3.
- `django.test.utils.patch_logger()` - Use `unittest.TestCase.assertLogs()` instead.
- `django.utils.lru_cache.lru_cache()` - Alias of `functools.lru_cache()`.
- `django.utils.decorators.available_attrs()` - This function returns `functools.WRAPPER_ASSIGNMENTS`.
- `django.utils.decorators.ContextDecorator` - Alias of `contextlib.ContextDecorator`.
- `django.utils._os.abspathu()` - Alias of `os.path.abspath()`.

- `django.utils._os.upath()` and `npath()` - These functions do nothing on Python 3.
- `django.utils.six` - Remove usage of this vendored library or switch to [six](#).
- `django.utils.encoding.python_2_unicode_compatible()` - Alias of `six.python_2_unicode_compatible()`.
- `django.utils.functional.curry()` - Use `functools.partial()` or `functools.partialmethod`. See [5b1c389603a353625ae1603ba345147356336afb](#).
- `django.utils.safestring.SafeBytes` - Unused since Django 2.0.

New default value for the `FILE_UPLOAD_PERMISSIONS` setting

In older versions, the `FILE_UPLOAD_PERMISSIONS` setting defaults to `None`. With the default `FILE_UPLOAD_HANDLERS`, this results in uploaded files having different permissions depending on their size and which upload handler is used.

`FILE_UPLOAD_PERMISSIONS` now defaults to `0o644` to avoid this inconsistency.

New default values for security settings

To make Django projects more secure by default, some security settings now have more secure default values:

- `X_FRAME_OPTIONS` now defaults to `'DENY'`.
- `SECURE_CONTENT_TYPE_NOSNIFF` now defaults to `True`.

See the [What's New Security section](#) above for more details on these changes.

Miscellaneous

- `ContentType.__str__()` now includes the model's `app_label` to disambiguate models with the same name in different apps.
- Because accessing the language in the session rather than in the cookie is deprecated, `LocaleMiddleware` no longer looks for the user's language in the session and `django.contrib.auth.logout()` no longer preserves the session's language after logout.
- `django.utils.html.escape()` now uses `html.escape()` to escape HTML. This converts `'` to `'` instead of the previous equivalent decimal code `'`.
- The `django-admin test -k` option now works as the `unittest -k` option rather than as a shortcut for `--keepdb`.
- Support for `pywatchman < 1.2.0` is removed.
- `urlencode()` now encodes iterable values as they are when `doseq=False`, rather than iterating them, bringing it into line with the standard library `urllib.parse.urlencode()` function.

- `intword` template filter now translates 1.0 as a singular phrase and all other numeric values as plural. This may be incorrect for some languages.
- Assigning a value to a model's `ForeignKey` or `OneToOneField` `'_id'` attribute now unsets the corresponding field. Accessing the field afterward will result in a query.
- `patch_vary_headers()` now handles an asterisk `'*'` according to RFC 7231#section-7.1.4, i.e. if a list of header field names contains an asterisk, then the `Vary` header will consist of a single asterisk `'*'`.
- On MySQL 8.0.16+, `PositiveIntegerField` and `PositiveSmallIntegerField` now include a check constraint to prevent negative values in the database.
- `alias=None` is added to the signature of `Expression.get_group_by_cols()`.
- `RegexPattern`, used by `re_path()`, no longer returns keyword arguments with `None` values to be passed to the view for the optional named groups that are missing.

Features deprecated in 3.0

`django.utils.encoding.force_text()` and `smart_text()`

The `smart_text()` and `force_text()` aliases (since Django 2.0) of `smart_str()` and `force_str()` are deprecated. Ignore this deprecation if your code supports Python 2 as the behavior of `smart_str()` and `force_str()` is different there.

Miscellaneous

- `django.utils.http.urlquote()`, `urlquote_plus()`, `urlunquote()`, and `urlunquote_plus()` are deprecated in favor of the functions that they're aliases for: `urllib.parse.quote()`, `quote_plus()`, `unquote()`, and `unquote_plus()`.
- `django.utils.translation.ugettext()`, `ugettext_lazy()`, `ugettext_noop()`, `ungettext()`, and `ungettext_lazy()` are deprecated in favor of the functions that they're aliases for: `django.utils.translation.gettext()`, `gettext_lazy()`, `gettext_noop()`, `nggettext()`, and `nggettext_lazy()`.
- To limit creation of sessions and hence favor some caching strategies, `django.views.i18n.set_language()` will stop setting the user's language in the session in Django 4.0. Since Django 2.1, the language is always stored in the `LANGUAGE_COOKIE_NAME` cookie.
- `django.utils.text.unescape_entities()` is deprecated in favor of `html.unescape()`. Note that unlike `unescape_entities()`, `html.unescape()` evaluates lazy strings immediately.
- To avoid possible confusion as to effective scope, the private internal utility `is_safe_url()` is renamed to `url_has_allowed_host_and_scheme()`. That a URL has an allowed host and scheme doesn't in general imply that it's "safe". It may still be quoted incorrectly, for example. Ensure to also use `iri_to_uri()` on the path component of untrusted URLs.

Features removed in 3.0

These features have reached the end of their deprecation cycle and are removed in Django 3.0.

See [Features deprecated in 2.0](#) for details on these changes, including how to remove usage of these features.

- The `django.db.backends.postgresql_psycopg2` module is removed.
- `django.shortcuts.render_to_response()` is removed.
- The `DEFAULT_CONTENT_TYPE` setting is removed.
- `HttpRequest.xreadlines()` is removed.
- Support for the `context` argument of `Field.from_db_value()` and `Expression.convert_value()` is removed.
- The `field_name` keyword argument of `QuerySet.earliest()` and `latest()` is removed.

See [Features deprecated in 2.1](#) for details on these changes, including how to remove usage of these features.

- The `ForceRHR` GIS function is removed.
- `django.utils.http.cookie_date()` is removed.
- The `staticfiles` and `admin_static` template tag libraries are removed.
- `django.contrib.staticfiles.templatetags.staticfiles.static()` is removed.

9.1.7 2.2 release

Django 2.2.28 release notes

April 11, 2022

Django 2.2.28 fixes two security issues with severity “high” in 2.2.27.

CVE-2022-28346: Potential SQL injection in `QuerySet.annotate()`, `aggregate()`, and `extra()`

`QuerySet.annotate()`, *`aggregate()`*, and *`extra()`* methods were subject to SQL injection in column aliases, using a suitably crafted dictionary, with dictionary expansion, as the **`**kwargs`** passed to these methods.

CVE-2022-28347: Potential SQL injection via `QuerySet.explain(**options)` on PostgreSQL

`QuerySet.explain()` method was subject to SQL injection in option names, using a suitably crafted dictionary, with dictionary expansion, as the `**options` argument.

Django 2.2.27 release notes

February 1, 2022

Django 2.2.27 fixes two security issues with severity “medium” in 2.2.26.

CVE-2022-22818: Possible XSS via `{% debug %}` template tag

The `{% debug %}` template tag didn’t properly encode the current context, posing an XSS attack vector.

In order to avoid this vulnerability, `{% debug %}` no longer outputs information when the `DEBUG` setting is `False`, and it ensures all context variables are correctly escaped when the `DEBUG` setting is `True`.

CVE-2022-23833: Denial-of-service possibility in file uploads

Passing certain inputs to multipart forms could result in an infinite loop when parsing files.

Django 2.2.26 release notes

January 4, 2022

Django 2.2.26 fixes one security issue with severity “medium” and two security issues with severity “low” in 2.2.25.

CVE-2021-45115: Denial-of-service possibility in `UserAttributeSimilarityValidator`

`UserAttributeSimilarityValidator` incurred significant overhead evaluating submitted password that were artificially large in relative to the comparison values. On the assumption that access to user registration was unrestricted this provided a potential vector for a denial-of-service attack.

In order to mitigate this issue, relatively long values are now ignored by `UserAttributeSimilarityValidator`.

This issue has severity “medium” according to the [Django security policy](#).

CVE-2021-45116: Potential information disclosure in `dictsort` template filter

Due to leveraging the Django Template Language’s variable resolution logic, the `dictsort` template filter was potentially vulnerable to information disclosure or unintended method calls, if passed a suitably crafted key.

In order to avoid this possibility, `dictsort` now works with a restricted resolution logic, that will not call methods, nor allow indexing on dictionaries.

As a reminder, all untrusted user input should be validated before use.

This issue has severity “low” according to the [Django security policy](#).

CVE-2021-45452: Potential directory-traversal via `Storage.save()`

`Storage.save()` allowed directory-traversal if directly passed suitably crafted file names.

This issue has severity “low” according to the [Django security policy](#).

Django 2.2.25 release notes

December 7, 2021

Django 2.2.25 fixes a security issue with severity “low” in 2.2.24.

CVE-2021-44420: Potential bypass of an upstream access control based on URL paths

HTTP requests for URLs with trailing newlines could bypass an upstream access control based on URL paths.

Django 2.2.24 release notes

June 2, 2021

Django 2.2.24 fixes two security issues in 2.2.23.

CVE-2021-33203: Potential directory traversal via `admindocs`

Staff members could use the `admindocs` `TemplateDetailView` view to check the existence of arbitrary files. Additionally, if (and only if) the default `admindocs` templates have been customized by the developers to also expose the file contents, then not only the existence but also the file contents would have been exposed.

As a mitigation, path sanitation is now applied and only files within the template root directories can be loaded.

CVE-2021-33571: Possible indeterminate SSRF, RFI, and LFI attacks since validators accepted leading zeros in IPv4 addresses

`URLValidator`, `validate_ipv4_address()`, and `validate_ipv6_address()` didn't prohibit leading zeros in octal literals. If you used such values you could suffer from indeterminate SSRF, RFI, and LFI attacks.

`validate_ipv4_address()` and `validate_ipv6_address()` validators were not affected on Python 3.9.5+.

Django 2.2.23 release notes

May 13, 2021

Django 2.2.23 fixes a regression in 2.2.21.

Bugfixes

- Fixed a regression in Django 2.2.21 where saving `FileField` would raise a `SuspiciousFileOperation` even when a custom `upload_to` returns a valid file path (#32718).

Django 2.2.22 release notes

May 6, 2021

Django 2.2.22 fixes a security issue in 2.2.21.

CVE-2021-32052: Header injection possibility since `URLValidator` accepted newlines in input on Python 3.9.5+

On Python 3.9.5+, `URLValidator` didn't prohibit newlines and tabs. If you used values with newlines in HTTP response, you could suffer from header injection attacks. Django itself wasn't vulnerable because `HttpResponse` prohibits newlines in HTTP headers.

Moreover, the `URLField` form field which uses `URLValidator` silently removes newlines and tabs on Python 3.9.5+, so the possibility of newlines entering your data only existed if you are using this validator outside of the form fields.

This issue was introduced by the [bpo-43882](#) fix.

Django 2.2.21 release notes

May 4, 2021

Django 2.2.21 fixes a security issue in 2.2.20.

CVE-2021-31542: Potential directory-traversal via uploaded files

`MultiPartParser`, `UploadedFile`, and `FieldFile` allowed directory-traversal via uploaded files with suitably crafted file names.

In order to mitigate this risk, stricter basename and path sanitation is now applied.

Django 2.2.20 release notes

April 6, 2021

Django 2.2.20 fixes a security issue with severity “low” in 2.2.19.

CVE-2021-28658: Potential directory-traversal via uploaded files

`MultiPartParser` allowed directory-traversal via uploaded files with suitably crafted file names.

Built-in upload handlers were not affected by this vulnerability.

Django 2.2.19 release notes

February 19, 2021

Django 2.2.19 fixes a security issue in 2.2.18.

CVE-2021-23336: Web cache poisoning via `django.utils.http.limited_parse_qs1()`

Django contains a copy of `urllib.parse.parse_qs1()` which was added to backport some security fixes. A further security fix has been issued recently such that `parse_qs1()` no longer allows using `;` as a query parameter separator by default. Django now includes this fix. See [bpo-42967](#) for further details.

Django 2.2.18 release notes

February 1, 2021

Django 2.2.18 fixes a security issue with severity “low” in 2.2.17.

CVE-2021-3281: Potential directory-traversal via `archive.extract()`

The `django.utils.archive.extract()` function, used by `startapp --template` and `startproject --template`, allowed directory-traversal via an archive with absolute paths or relative paths with dot segments.

Django 2.2.17 release notes

November 2, 2020

Django 2.2.17 adds compatibility with Python 3.9.

Django 2.2.16 release notes

September 1, 2020

Django 2.2.16 fixes two security issues and two data loss bugs in 2.2.15.

CVE-2020-24583: Incorrect permissions on intermediate-level directories on Python 3.7+

On Python 3.7+, `FILE_UPLOAD_DIRECTORY_PERMISSIONS` mode was not applied to intermediate-level directories created in the process of uploading files and to intermediate-level collected static directories when using the `collectstatic` management command.

You should review and manually fix permissions on existing intermediate-level directories.

CVE-2020-24584: Permission escalation in intermediate-level directories of the file system cache on Python 3.7+

On Python 3.7+, the intermediate-level directories of the file system cache had the system’s standard umask rather than `0o077` (no group or others permissions).

Bugfixes

- Fixed a data loss possibility in the `select_for_update()`. When using related fields pointing to a proxy model in the `of` argument, the corresponding model was not locked (#31866).
- Fixed a data loss possibility, following a regression in Django 2.0, when copying model instances with a cached fields value (#31863).

Django 2.2.15 release notes

August 3, 2020

Django 2.2.15 fixes two bugs in 2.2.14.

Bugfixes

- Allowed setting the `SameSite` cookie flag in `HttpResponse.delete_cookie()` (#31790).
- Fixed crash when sending emails to addresses with display names longer than 75 chars on Python 3.6.11+, 3.7.8+, and 3.8.4+ (#31784).

Django 2.2.14 release notes

July 1, 2020

Django 2.2.14 fixes a bug in 2.2.13.

Bugfixes

- Fixed messages of `InvalidCacheKey` exceptions and `CacheKeyWarning` warnings raised by cache key validation (#31654).

Django 2.2.13 release notes

June 3, 2020

Django 2.2.13 fixes two security issues and a regression in 2.2.12.

CVE-2020-13254: Potential data leakage via malformed memcached keys

In cases where a memcached backend does not perform key validation, passing malformed cache keys could result in a key collision, and potential data leakage. In order to avoid this vulnerability, key validation is added to the memcached cache backends.

CVE-2020-13596: Possible XSS via admin `ForeignKeyRawIdWidget`

Query parameters for the admin `ForeignKeyRawIdWidget` were not properly URL encoded, posing an XSS attack vector. `ForeignKeyRawIdWidget` now ensures query parameters are correctly URL encoded.

Bugfixes

- Fixed a regression in Django 2.2.12 that affected translation loading for apps providing translations for territorial language variants as well as a generic language, where the project has different plural equations for the language (#31570).
- Tracking a jQuery security release, upgraded the version of jQuery used by the admin from 3.3.1 to 3.5.1.

Django 2.2.12 release notes

April 1, 2020

Django 2.2.12 fixes a bug in 2.2.11.

Bugfixes

- Added the ability to handle `.po` files containing different plural equations for the same language (#30439).

Django 2.2.11 release notes

March 4, 2020

Django 2.2.11 fixes a security issue and a data loss bug in 2.2.10.

CVE-2020-9402: Potential SQL injection via `tolerance` parameter in GIS functions and aggregates on Oracle

GIS functions and aggregates on Oracle were subject to SQL injection, using a suitably crafted `tolerance`.

Bugfixes

- Fixed a data loss possibility in the `select_for_update()`. When using related fields or parent link fields with [Multi-table inheritance](#) in the `of` argument, the corresponding models were not locked ([#31246](#)).

Django 2.2.10 release notes

February 3, 2020

Django 2.2.10 fixes a security issue in 2.2.9.

CVE-2020-7471: Potential SQL injection via `StringAgg(delimiter)`

`StringAgg` aggregation function was subject to SQL injection, using a suitably crafted `delimiter`.

Django 2.2.9 release notes

December 18, 2019

Django 2.2.9 fixes a security issue and a data loss bug in 2.2.8.

CVE-2019-19844: Potential account hijack via password reset form

By submitting a suitably crafted email address making use of Unicode characters, that compared equal to an existing user email when lower-cased for comparison, an attacker could be sent a password reset token for the matched account.

In order to avoid this vulnerability, password reset requests now compare the submitted email using the stricter, recommended algorithm for case-insensitive comparison of two identifiers from [Unicode Technical Report 36, section 2.11.2\(B\)\(2\)](#). Upon a match, the email containing the reset token will be sent to the email address on record rather than the submitted address.

Bugfixes

- Fixed a data loss possibility in *SplitArrayField*. When using with `ArrayField(BooleanField())`, all values after the first `True` value were marked as checked instead of preserving passed values ([#31073](#)).

Django 2.2.8 release notes

December 2, 2019

Django 2.2.8 fixes a security issue, several bugs in 2.2.7, and adds compatibility with Python 3.8.

CVE-2019-19118: Privilege escalation in the Django admin.

Since Django 2.1, a Django model admin displaying a parent model with related model inlines, where the user has view-only permissions to a parent model but edit permissions to the inline model, would display a read-only view of the parent model but editable forms for the inline.

Submitting these forms would not allow direct edits to the parent model, but would trigger the parent model's `save()` method, and cause pre and post-save signal handlers to be invoked. This is a privilege escalation as a user who lacks permission to edit a model should not be able to trigger its save-related signals.

To resolve this issue, the permission handling code of the Django admin interface has been changed. Now, if a user has only the “view” permission for a parent model, the entire displayed form will not be editable, even if the user has permission to edit models included in inlines.

This is a backwards-incompatible change, and the Django security team is aware that some users of Django were depending on the ability to allow editing of inlines in the admin form of an otherwise view-only parent model.

Given the complexity of the Django admin, and in-particular the permissions related checks, it is the view of the Django security team that this change was necessary: that it is not currently feasible to maintain the existing behavior while escaping the potential privilege escalation in a way that would avoid a recurrence of similar issues in the future, and that would be compatible with Django's safe by default philosophy.

For the time being, developers whose applications are affected by this change should replace the use of inlines in read-only parents with custom forms and views that explicitly implement the desired functionality. In the longer term, adding a documented, supported, and properly-tested mechanism for partially-editable multi-model forms to the admin interface may occur in Django itself.

Bugfixes

- Fixed a data loss possibility in the admin changelist view when a custom `formset`'s prefix contains regular expression special characters, e.g. '\$' (#31031).
- Fixed a regression in Django 2.2.1 that caused a crash when migrating permissions for proxy models with a multiple database setup if the default entry was empty (#31021).
- Fixed a data loss possibility in the `select_for_update()`. When using 'self' in the of argument with multi-table inheritance, a parent model was locked instead of the queryset's model (#30953).

Django 2.2.7 release notes

November 4, 2019

Django 2.2.7 fixes several bugs in 2.2.6.

Bugfixes

- Fixed a crash when using a `contains`, `contained_by`, `has_key`, `has_keys`, or `has_any_keys` lookup on `django.contrib.postgres.fields.JSONField`, if the right or left hand side of an expression is a key transform (#30826).
- Prevented `migrate --plan` from showing that RunPython operations are irreversible when `reverse_code` callables don't have docstrings or when showing a forward migration plan (#30870).
- Fixed migrations crash on PostgreSQL when adding an `Index` with fields ordering and `opclasses` (#30903).
- Restored the ability to override `get_FOO_display()` (#30931).

Django 2.2.6 release notes

October 1, 2019

Django 2.2.6 fixes several bugs in 2.2.5.

Bugfixes

- Fixed migrations crash on SQLite when altering a model containing partial indexes (#30754).
- Fixed a regression in Django 2.2.4 that caused a crash when filtering with a `Subquery()` annotation of a queryset containing `django.contrib.postgres.fields.JSONField` or `HStoreField` (#30769).

Django 2.2.5 release notes

September 2, 2019

Django 2.2.5 fixes several bugs in 2.2.4.

Bugfixes

- Relaxed the system check added in Django 2.2 for models to realow use of the same `db_table` by multiple models when database routers are installed (#30673).
- Fixed crash of `KeyTransform()` for `django.contrib.postgres.fields.JSONField` and `HStoreField` when using on expressions with params (#30672).
- Fixed a regression in Django 2.2 where `ModelAdmin.list_filter` choices to foreign objects don't respect a model's `Meta.ordering` (#30449).

Django 2.2.4 release notes

August 1, 2019

Django 2.2.4 fixes security issues and several bugs in 2.2.3.

CVE-2019-14232: Denial-of-service possibility in `django.utils.text.Truncator`

If `django.utils.text.Truncator`'s `chars()` and `words()` methods were passed the `html=True` argument, they were extremely slow to evaluate certain inputs due to a catastrophic backtracking vulnerability in a regular expression. The `chars()` and `words()` methods are used to implement the `truncatechars_html` and `truncatewords_html` template filters, which were thus vulnerable.

The regular expressions used by `Truncator` have been simplified in order to avoid potential backtracking issues. As a consequence, trailing punctuation may now at times be included in the truncated output.

CVE-2019-14233: Denial-of-service possibility in `strip_tags()`

Due to the behavior of the underlying `HTMLParser`, `django.utils.html.strip_tags()` would be extremely slow to evaluate certain inputs containing large sequences of nested incomplete HTML entities. The `strip_tags()` method is used to implement the corresponding `striptags` template filter, which was thus also vulnerable.

`strip_tags()` now avoids recursive calls to `HTMLParser` when progress removing tags, but necessarily incomplete HTML entities, stops being made.

Remember that absolutely NO guarantee is provided about the results of `strip_tags()` being HTML safe. So NEVER mark safe the result of a `strip_tags()` call without escaping it first, for example with `django.utils.html.escape()`.

CVE-2019-14234: SQL injection possibility in key and index lookups for `JSONField`/`HStoreField`

Key and index lookups for `django.contrib.postgres.fields.JSONField` and *key lookups* for `HStoreField` were subject to SQL injection, using a suitably crafted dictionary, with dictionary expansion, as the `**kwargs` passed to `QuerySet.filter()`.

CVE-2019-14235: Potential memory exhaustion in `django.utils.encoding.uri_to_iri()`

If passed certain inputs, `django.utils.encoding.uri_to_iri()` could lead to significant memory usage due to excessive recursion when re-percent-encoding invalid UTF-8 octet sequences.

`uri_to_iri()` now avoids recursion when re-percent-encoding invalid UTF-8 octet sequences.

Bugfixes

- Fixed a regression in Django 2.2 when ordering a `QuerySet.union()`, `intersection()`, or `difference()` by a field type present more than once results in the wrong ordering being used (#30628).
- Fixed a migration crash on PostgreSQL when adding a check constraint with a `contains` lookup on `DateRangeField` or `DateTimeRangeField`, if the right hand side of an expression is the same type (#30621).
- Fixed a regression in Django 2.2 where auto-reloader crashes if a file path contains null characters (`'\x00'`) (#30506).
- Fixed a regression in Django 2.2 where auto-reloader crashes if a translation directory cannot be resolved (#30647).

Django 2.2.3 release notes

July 1, 2019

Django 2.2.3 fixes a security issue and several bugs in 2.2.2. Also, the latest string translations from Transifex are incorporated.

CVE-2019-12781: Incorrect HTTP detection with reverse-proxy connecting via HTTPS

When deployed behind a reverse-proxy connecting to Django via HTTPS, `django.http.HttpRequest.scheme` would incorrectly detect client requests made via HTTP as using HTTPS. This entails incorrect results for `is_secure()`, and `build_absolute_uri()`, and that HTTP requests would not be redirected to HTTPS in accordance with `SECURE_SSL_REDIRECT`.

`HttpRequest.scheme` now respects `SECURE_PROXY_SSL_HEADER`, if it is configured, and the appropriate header is set on the request, for both HTTP and HTTPS requests.

If you deploy Django behind a reverse-proxy that forwards HTTP requests, and that connects to Django via HTTPS, be sure to verify that your application correctly handles code paths relying on `scheme`, `is_secure()`, `build_absolute_uri()`, and `SECURE_SSL_REDIRECT`.

Bugfixes

- Fixed a regression in Django 2.2 where `Avg`, `StdDev`, and `Variance` crash with `filter` argument (#30542).
- Fixed a regression in Django 2.2.2 where auto-reloader crashes with `AttributeError`, e.g. when using `ipdb` (#30588).

Django 2.2.2 release notes

June 3, 2019

Django 2.2.2 fixes security issues and several bugs in 2.2.1.

CVE-2019-12308: AdminURLFieldWidget XSS

The clickable “Current URL” link generated by `AdminURLFieldWidget` displayed the provided value without validating it as a safe URL. Thus, an unvalidated value stored in the database, or a value provided as a URL query parameter payload, could result in an clickable JavaScript link.

`AdminURLFieldWidget` now validates the provided value using `URLValidator` before displaying the clickable link. You may customize the validator by passing a `validator_class` kwarg to `AdminURLFieldWidget.__init__()`, e.g. when using `formfield_overrides`.

Patched bundled jQuery for CVE-2019-11358: Prototype pollution

jQuery before 3.4.0, mishandles `jQuery.extend(true, {}, ...)` because of `Object.prototype` pollution. If an unsanitized source object contained an enumerable `__proto__` property, it could extend the native `Object.prototype`.

The bundled version of jQuery used by the Django admin has been patched to allow for the `select2` library's use of `jQuery.extend()`.

Bugfixes

- Fixed a regression in Django 2.2 that stopped Show/Hide toggles working on dynamically added admin inlines (#30459).
- Fixed a regression in Django 2.2 where deprecation message crashes if `Meta.ordering` contains an expression (#30463).
- Fixed a regression in Django 2.2.1 where *SearchVector* generates SQL with a redundant `Coalesce` call (#30488).
- Fixed a regression in Django 2.2 where auto-reloader doesn't detect changes in `manage.py` file when using `StatReloader` (#30479).
- Fixed crash of *ArrayAgg* and *StringAgg* with `ordering` argument when used in a Subquery (#30315).
- Fixed a regression in Django 2.2 that caused a crash of auto-reloader when an exception with custom signature is raised (#30516).
- Fixed a regression in Django 2.2.1 where auto-reloader unnecessarily reloads translation files multiple times when using `StatReloader` (#30523).

Django 2.2.1 release notes

May 1, 2019

Django 2.2.1 fixes several bugs in 2.2.

Bugfixes

- Fixed a regression in Django 2.1 that caused the incorrect quoting of database user password when using *dbshell* on Oracle (#30307).
- Added compatibility for `psycopg2` 2.8 (#30331).
- Fixed a regression in Django 2.2 that caused a crash when loading the template for the technical 500 debug page (#30324).

- Fixed crash of `ordering` argument in `ArrayAgg` and `StringAgg` when it contains an expression with params (#30332).
- Fixed a regression in Django 2.2 that caused a single instance fast-delete to not set the primary key to `None` (#30330).
- Prevented `makemigrations` from generating infinite migrations for check constraints and partial indexes when `condition` contains a `range` object (#30350).
- Reverted an optimization in Django 2.2 (#29725) that caused the inconsistent behavior of `count()` and `exists()` on a reverse many-to-many relationship with a custom manager (#30325).
- Fixed a regression in Django 2.2 where `Paginator` crashes if `object_list` is a queryset ordered or aggregated over a nested `JSONField` key transform (#30335).
- Fixed a regression in Django 2.2 where `IntegerField` validation of database limits crashes if `limit_value` attribute in a custom validator is callable (#30328).
- Fixed a regression in Django 2.2 where `SearchVector` generates SQL that is not indexable (#30385).
- Fixed a regression in Django 2.2 that caused an exception to be raised when a custom error handler could not be imported (#30318).
- Relaxed the system check added in Django 2.2 for the admin app's dependencies to allow use of `SessionMiddleware` subclasses, rather than requiring `django.contrib.sessions` to be in `INSTALLED_APPS` (#30312).
- Increased the default timeout when using `Watchman` to 5 seconds to prevent falling back to `StatReloader` on larger projects and made it customizable via the `DJANGO_WATCHMAN_TIMEOUT` environment variable (#30361).
- Fixed a regression in Django 2.2 that caused a crash when migrating permissions for proxy models if the target permissions already existed. For example, when a permission had been created manually or a model had been migrated from concrete to proxy (#30351).
- Fixed a regression in Django 2.2 that caused a crash of `runserver` when `URLConf` modules raised exceptions (#30323).
- Fixed a regression in Django 2.2 where changes were not reliably detected by auto-reloader when using `StatReloader` (#30323).
- Fixed a migration crash on Oracle and PostgreSQL when adding a check constraint with a `contains`, `startswith`, or `endswith` lookup (or their case-insensitive variant) (#30408).
- Fixed a migration crash on Oracle and SQLite when adding a check constraint with `condition` contains `|` (OR) operator (#30412).

Django 2.2 release notes

April 1, 2019

Welcome to Django 2.2!

These release notes cover the [new features](#), as well as some [backwards incompatible changes](#) you’ ll want to be aware of when upgrading from Django 2.1 or earlier. We’ ve begun [the deprecation process](#) for some features.

See the [How to upgrade Django to a newer version](#) guide if you’ re updating an existing project.

Django 2.2 is designated as a [long-term support release](#). It will receive security updates for at least three years after its release. Support for the previous LTS, Django 1.11, will end in April 2020.

Python compatibility

Django 2.2 supports Python 3.5, 3.6, 3.7, 3.8 (as of 2.2.8), and 3.9 (as of 2.2.17). We highly recommend and only officially support the latest release of each series.

What’ s new in Django 2.2

Constraints

The new *CheckConstraint* and *UniqueConstraint* classes enable adding custom database constraints. Constraints are added to models using the *Meta.constraints* option.

Minor features

`django.contrib.admin`

- Added a CSS class to the column headers of *TabularInline*.

`django.contrib.auth`

- The `HttpRequest` is now passed as the first positional argument to *RemoteUserBackend.configure_user()*, if it accepts it.

`django.contrib.gis`

- Added Oracle support for the *Envelope* function.
- Added SpatiaLite support for the *coveredby* and *covers* lookups.

`django.contrib.postgres`

- The new `ordering` argument for *ArrayAgg* and *StringAgg* determines the ordering of the aggregated elements.
- The new *BTreeIndex*, *HashIndex* and *SpGistIndex* classes allow creating B-Tree, hash, and SP-GiST indexes in the database.
- *BrinIndex* now has the `autosummarize` parameter.
- The new `search_type` parameter of *SearchQuery* allows searching for a phrase or raw expression.

`django.contrib.staticfiles`

- Added path matching to the *collectstatic* `--ignore` option so that patterns like `/vendor/*.js` can be used.

Database backends

- Added result streaming for *QuerySet.iterator()* on SQLite.

Generic Views

- The new *View.setup* hook initializes view attributes before calling *dispatch()*. It allows mixins to set up instance attributes for reuse in child classes.

Internationalization

- Added support and translations for the Armenian language.

Management Commands

- The new `--force-color` option forces colorization of the command output.
- `inspectdb` now creates models for foreign tables on PostgreSQL.
- `inspectdb --include-views` now creates models for materialized views on Oracle and PostgreSQL.
- The new `inspectdb --include-partitions` option allows creating models for partition tables on PostgreSQL. In older versions, models are created child tables instead the parent.
- `inspectdb` now introspects `DurationField` for Oracle and PostgreSQL, and `AutoField` for SQLite.
- On Oracle, `dbshell` is wrapped with `rlwrap`, if available. `rlwrap` provides a command history and editing of keyboard input.
- The new `makemigrations --no-header` option avoids writing header comments in generated migration file(s). This option is also available for `squashmigrations`.
- `runserver` can now use `Watchman` to improve the performance of watching a large number of files for changes.

Migrations

- The new `migrate --plan` option prints the list of migration operations that will be performed.
- `NoneType` can now be serialized in migrations.
- You can now `register custom serializers` for migrations.

Models

- Added support for PostgreSQL operator classes (`Index.opclasses`).
- Added support for partial indexes (`Index.condition`).
- Added the `NullIf` and `Reverse` database functions, as well as many `math database functions`.
- Setting the new `ignore_conflicts` parameter of `QuerySet.bulk_create()` to `True` tells the database to ignore failure to insert rows that fail uniqueness constraints or other checks.
- The new `ExtractIsoYear` function extracts ISO-8601 week-numbering years from `DateField` and `DateTimeField`, and the new `iso_year` lookup allows querying by an ISO-8601 week-numbering year.
- The new `QuerySet.bulk_update()` method allows efficiently updating specific fields on multiple model instances.
- Django no longer always starts a transaction when a single query is being performed, such as `Model.save()`, `QuerySet.update()`, and `Model.delete()`. This improves the performance of autocommit by reducing the number of database round trips.

- Added SQLite support for the `StdDev` and `Variance` functions.
- The handling of DISTINCT aggregation is added to the `Aggregate` class. Adding `allow_distinct = True` as a class attribute on `Aggregate` subclasses allows a `distinct` keyword argument to be specified on initialization to ensure that the aggregate function is only called for each distinct value of expressions.
- The `RelatedManager.add()`, `create()`, `remove()`, `set()`, `get_or_create()`, and `update_or_create()` methods are now allowed on many-to-many relationships with intermediate models. The new `through_defaults` argument is used to specify values for new intermediate model instance(s).

Requests and Responses

- Added `HttpRequest.headers` to allow simple access to a request's headers.

Serialization

- You can now deserialize data using natural keys containing forward references by passing `handle_forward_references=True` to `serializers.deserialize()`. Additionally, `loaddata` handles forward references automatically.

Tests

- The new `SimpleTestCase.assertURLEqual()` assertion checks for a given URL, ignoring the ordering of the query string. `assertRedirects()` uses the new assertion.
- The test `Client` now supports automatic JSON serialization of list and tuple data when `content_type='application/json'`.
- The new `ORACLE_MANAGED_FILES` test database setting allows using Oracle Managed Files (OMF) tablespaces.
- Deferrable database constraints are now checked at the end of each `TestCase` test on SQLite 3.20+, just like on other backends that support deferrable constraints. These checks aren't implemented for older versions of SQLite because they would require expensive table introspection there.
- `DiscoverRunner` now skips the setup of databases not referenced by tests.

URLs

- The new *ResolverMatch.route* attribute stores the route of the matching URL pattern.

Validators

- *MaxValueValidator*, *MinValueValidator*, *MinLengthValidator*, and *MaxLengthValidator* now accept a callable `limit_value`.

Backwards incompatible changes in 2.2

Database backend API

This section describes changes that may be needed in third-party database backends.

- Third-party database backends must implement support for table check constraints or set `DatabaseFeatures.supports_table_check_constraints` to `False`.
- Third party database backends must implement support for ignoring constraints or uniqueness errors while inserting or set `DatabaseFeatures.supports_ignore_conflicts` to `False`.
- Third party database backends must implement introspection for `DurationField` or set `DatabaseFeatures.can_introspect_duration_field` to `False`.
- `DatabaseFeatures.uses_savepoints` now defaults to `True`.
- Third party database backends must implement support for partial indexes or set `DatabaseFeatures.supports_partial_indexes` to `False`.
- `DatabaseIntrospection.table_name_converter()` and `column_name_converter()` are removed. Third party database backends may need to instead implement `DatabaseIntrospection.identifier_converter()`. In that case, the constraint names that `DatabaseIntrospection.get_constraints()` returns must be normalized by `identifier_converter()`.
- SQL generation for indexes is moved from *Index* to *SchemaEditor* and these *SchemaEditor* methods are added:
 - `_create_primary_key_sql()` and `_delete_primary_key_sql()`
 - `_delete_index_sql()` (to pair with `_create_index_sql()`)
 - `_delete_unique_sql()` (to pair with `_create_unique_sql()`)
 - `_delete_fk_sql()` (to pair with `_create_fk_sql()`)
 - `_create_check_sql()` and `_delete_check_sql()`
- The third argument of `DatabaseWrapper.__init__()`, `allow_thread_sharing`, is removed.

Admin actions are no longer collected from base `ModelAdmin` classes

For example, in older versions of Django:

```
from django.contrib import admin

class BaseAdmin(admin.ModelAdmin):
    actions = ["a"]

class SubAdmin(BaseAdmin):
    actions = ["b"]
```

`SubAdmin` would have actions 'a' and 'b'.

Now `actions` follows standard Python inheritance. To get the same result as before:

```
class SubAdmin(BaseAdmin):
    actions = BaseAdmin.actions + ["b"]
```

`django.contrib.gis`

- Support for GDAL 1.9 and 1.10 is dropped.

`TransactionTestCase` serialized data loading

Initial data migrations are now loaded in `TransactionTestCase` at the end of the test, after the database flush. In older versions, this data was loaded at the beginning of the test, but this prevents the `test --keepdb` option from working properly (the database was empty at the end of the whole test suite). This change shouldn't have an impact on your tests unless you've customized `TransactionTestCase`'s internals.

`sqlparse` is required dependency

To simplify a few parts of Django's database handling, `sqlparse 0.2.2+` is now a required dependency. It's automatically installed along with Django.

cached_property aliases

In usage like:

```
from django.utils.functional import cached_property

class A:
    @cached_property
    def base(self):
        return ...

    alias = base
```

`alias` is not cached. Where the problem can be detected (Python 3.6 and later), such usage now raises `TypeError: Cannot assign the same cached_property to two different names ('base' and 'alias')`.

Use this instead:

```
import operator

class A:
    ...

    alias = property(operator.attrgetter("base"))
```

Permissions for proxy models

Permissions for proxy models are now created using the content type of the proxy model rather than the content type of the concrete model. A migration will update existing permissions when you run *migrate*.

In the admin, the change is transparent for proxy models having the same `app_label` as their concrete model. However, in older versions, users with permissions for a proxy model with a different `app_label` than its concrete model couldn't access the model in the admin. That's now fixed, but you might want to audit the permissions assignments for such proxy models (`[add|view|change|delete]_myproxy`) prior to upgrading to ensure the new access is appropriate.

Finally, proxy model permission strings must be updated to use their own `app_label`. For example, for `app.MyProxyModel` inheriting from `other_app.ConcreteModel`, update `user.has_perm('other_app.add_myproxymodel')` to `user.has_perm('app.add_myproxymodel')`.

Merging of form Media assets

Form Media assets are now merged using a topological sort algorithm, as the old pairwise merging algorithm is insufficient for some cases. CSS and JavaScript files which don't include their dependencies may now be sorted incorrectly (where the old algorithm produced results correctly by coincidence).

Audit all Media classes for any missing dependencies. For example, widgets depending on `django.jQuery` must specify `js=['admin/js/jquery.init.js', ...]` when [declaring form media assets](#).

Miscellaneous

- To improve readability, the `UUIDField` form field now displays values with dashes, e.g. `550e8400-e29b-41d4-a716-446655440000` instead of `550e8400e29b41d4a716446655440000`.
- On SQLite, `PositiveIntegerField` and `PositiveSmallIntegerField` now include a check constraint to prevent negative values in the database. If you have existing invalid data and run a migration that recreates a table, you'll see `CHECK constraint failed`.
- For consistency with WSGI servers, the test client now sets the `Content-Length` header to a string rather than an integer.
- The return value of `django.utils.text.slugify()` is no longer marked as HTML safe.
- The default truncation character used by the `urlizetrunc`, `truncatechars`, `truncatechars_html`, `truncatewords`, and `truncatewords_html` template filters is now the real ellipsis character (`...`) instead of 3 dots. You may have to adapt some test output comparisons.
- Support for bytestring paths in the template filesystem loader is removed.
- `django.utils.http.urlsafe_base64_encode()` now returns a string instead of a bytestring, and `django.utils.http.urlsafe_base64_decode()` may no longer be passed a bytestring.
- Support for `cx_Oracle < 6.0` is removed.
- The minimum supported version of `mysqlclient` is increased from 1.3.7 to 1.3.13.
- The minimum supported version of SQLite is increased from 3.7.15 to 3.8.3.
- In an attempt to provide more semantic query data, `NullBooleanSelect` now renders `<option>` values of `unknown`, `true`, and `false` instead of 1, 2, and 3. For backwards compatibility, the old values are still accepted as data.
- `Group.name` `max_length` is increased from 80 to 150 characters.
- Tests that violate deferrable database constraints now error when run on SQLite 3.20+, just like on other backends that support such constraints.
- To catch usage mistakes, the test `Client` and `django.utils.http.urlencode()` now raise `TypeError` if `None` is passed as a value to encode because `None` can't be encoded in GET and POST data. Either pass an empty string or omit the value.

- The `ping_google` management command now defaults to `https` instead of `http` for the sitemap's URL. If your site uses `http`, use the new `ping_google --sitemap-uses-http` option. If you use the `ping_google()` function, set the new `sitemap_uses_https` argument to `False`.
- `runserver` no longer supports `pyinotify` (replaced by `Watchman`).
- The `Avg`, `StdDev`, and `Variance` aggregate functions now return a `Decimal` instead of a `float` when the input is `Decimal`.
- Tests will fail on SQLite if apps without migrations have relations to apps with migrations. This has been a documented restriction since migrations were added in Django 1.7, but it fails more reliably now. You'll see tests failing with errors like `no such table: <app_label>_<model>`. This was observed with several third-party apps that had models in tests without migrations. You must add migrations for such models.
- Providing an integer in the `key` argument of the `cache.delete()` or `cache.get()` now raises `ValueError`.
- Plural equations for some languages are changed, because the latest versions from Transifex are incorporated.

Note: The ability to handle `.po` files containing different plural equations for the same language was added in Django 2.2.12.

Features deprecated in 2.2

Model `Meta.ordering` will no longer affect `GROUP BY` queries

A model's `Meta.ordering` affecting `GROUP BY` queries (such as `.annotate().values()`) is a common source of confusion. Such queries now issue a deprecation warning with the advice to add an `order_by()` to retain the current query. `Meta.ordering` will be ignored in such queries starting in Django 3.1.

Miscellaneous

- `django.utils.timezone.FixedOffset` is deprecated in favor of `datetime.timezone`.
- The undocumented `QuerySetPaginator` alias of `django.core.paginator.Paginator` is deprecated.
- The `FloatRangeField` model and form fields in `django.contrib.postgres` are deprecated in favor of a new name, `DecimalRangeField`, to match the underlying `numrange` data type used in the database.
- The `FILE_CHARSET` setting is deprecated. Starting with Django 3.1, files read from disk must be UTF-8 encoded.

- `django.contrib.staticfiles.storage.CachedStaticFilesStorage` is deprecated due to the intractable problems that it has. Use *ManifestStaticFilesStorage* or a third-party cloud storage instead.
- `RemoteUserBackend.configure_user()` is now passed `request` as the first positional argument, if it accepts it. Support for overrides that don't accept it will be removed in Django 3.1.
- The `SimpleTestCase.allow_database_queries`, `TransactionTestCase.multi_db`, and `TestCase.multi_db` attributes are deprecated in favor of *`SimpleTestCase.databases`*, *`TransactionTestCase.databases`*, and *`TestCase.databases`*. These new attributes allow databases dependencies to be declared in order to prevent unexpected queries against non-default databases to leak state between tests. The previous behavior of `allow_database_queries=True` and `multi_db=True` can be achieved by setting `databases='__all__'`.

9.1.8 2.1 release

Django 2.1.15 release notes

December 2, 2019

Django 2.1.15 fixes a security issue and a data loss bug in 2.1.14.

CVE-2019-19118: Privilege escalation in the Django admin.

Since Django 2.1, a Django model admin displaying a parent model with related model inlines, where the user has view-only permissions to a parent model but edit permissions to the inline model, would display a read-only view of the parent model but editable forms for the inline.

Submitting these forms would not allow direct edits to the parent model, but would trigger the parent model's `save()` method, and cause pre and post-save signal handlers to be invoked. This is a privilege escalation as a user who lacks permission to edit a model should not be able to trigger its save-related signals.

To resolve this issue, the permission handling code of the Django admin interface has been changed. Now, if a user has only the “view” permission for a parent model, the entire displayed form will not be editable, even if the user has permission to edit models included in inlines.

This is a backwards-incompatible change, and the Django security team is aware that some users of Django were depending on the ability to allow editing of inlines in the admin form of an otherwise view-only parent model.

Given the complexity of the Django admin, and in-particular the permissions related checks, it is the view of the Django security team that this change was necessary: that it is not currently feasible to maintain the existing behavior while escaping the potential privilege escalation in a way that would avoid a recurrence of similar issues in the future, and that would be compatible with Django's safe by default philosophy.

For the time being, developers whose applications are affected by this change should replace the use of inlines in read-only parents with custom forms and views that explicitly implement the desired functionality. In the longer term, adding a documented, supported, and properly-tested mechanism for partially-editable multi-model forms to the admin interface may occur in Django itself.

Bugfixes

- Fixed a data loss possibility in the `select_for_update()`. When using 'self' in the of argument with [multi-table inheritance](#), a parent model was locked instead of the queryset's model ([#30953](#)).

Django 2.1.14 release notes

November 4, 2019

Django 2.1.14 fixes a regression in 2.1.13.

Bugfixes

- Fixed a crash when using a `contains`, `contained_by`, `has_key`, `has_keys`, or `has_any_keys` lookup on `django.contrib.postgres.fields.JSONField`, if the right or left hand side of an expression is a key transform ([#30826](#)).

Django 2.1.13 release notes

October 1, 2019

Django 2.1.13 fixes a regression in 2.1.11.

Bugfixes

- Fixed a crash when filtering with a `Subquery()` annotation of a queryset containing `django.contrib.postgres.fields.JSONField` or `HStoreField` ([#30769](#)).

Django 2.1.12 release notes

September 2, 2019

Django 2.1.12 fixes a regression in 2.1.11.

Bugfixes

- Fixed crash of `KeyTransform()` for `django.contrib.postgres.fields.JSONField` and `HStoreField` when using on expressions with params (#30672).

Django 2.1.11 release notes

August 1, 2019

Django 2.1.11 fixes security issues in 2.1.10.

CVE-2019-14232: Denial-of-service possibility in `django.utils.text.Truncator`

If `django.utils.text.Truncator`'s `chars()` and `words()` methods were passed the `html=True` argument, they were extremely slow to evaluate certain inputs due to a catastrophic backtracking vulnerability in a regular expression. The `chars()` and `words()` methods are used to implement the `truncatechars_html` and `truncatewords_html` template filters, which were thus vulnerable.

The regular expressions used by `Truncator` have been simplified in order to avoid potential backtracking issues. As a consequence, trailing punctuation may now at times be included in the truncated output.

CVE-2019-14233: Denial-of-service possibility in `strip_tags()`

Due to the behavior of the underlying `HTMLParser`, `django.utils.html.strip_tags()` would be extremely slow to evaluate certain inputs containing large sequences of nested incomplete HTML entities. The `strip_tags()` method is used to implement the corresponding `striptags` template filter, which was thus also vulnerable.

`strip_tags()` now avoids recursive calls to `HTMLParser` when progress removing tags, but necessarily incomplete HTML entities, stops being made.

Remember that absolutely NO guarantee is provided about the results of `strip_tags()` being HTML safe. So NEVER mark safe the result of a `strip_tags()` call without escaping it first, for example with `django.utils.html.escape()`.

CVE-2019-14234: SQL injection possibility in key and index lookups for `JSONField`/`HStoreField`

Key and index lookups for `django.contrib.postgres.fields.JSONField` and *key lookups* for `HStoreField` were subject to SQL injection, using a suitably crafted dictionary, with dictionary expansion, as the `**kwargs` passed to `QuerySet.filter()`.

CVE-2019-14235: Potential memory exhaustion in `django.utils.encoding.uri_to_iri()`

If passed certain inputs, `django.utils.encoding.uri_to_iri()` could lead to significant memory usage due to excessive recursion when re-percent-encoding invalid UTF-8 octet sequences.

`uri_to_iri()` now avoids recursion when re-percent-encoding invalid UTF-8 octet sequences.

Django 2.1.10 release notes

July 1, 2019

Django 2.1.10 fixes a security issue in 2.1.9.

CVE-2019-12781: Incorrect HTTP detection with reverse-proxy connecting via HTTPS

When deployed behind a reverse-proxy connecting to Django via HTTPS, `django.http.HttpRequest.scheme` would incorrectly detect client requests made via HTTP as using HTTPS. This entails incorrect results for `is_secure()`, and `build_absolute_uri()`, and that HTTP requests would not be redirected to HTTPS in accordance with `SECURE_SSL_REDIRECT`.

`HttpRequest.scheme` now respects `SECURE_PROXY_SSL_HEADER`, if it is configured, and the appropriate header is set on the request, for both HTTP and HTTPS requests.

If you deploy Django behind a reverse-proxy that forwards HTTP requests, and that connects to Django via HTTPS, be sure to verify that your application correctly handles code paths relying on `scheme`, `is_secure()`, `build_absolute_uri()`, and `SECURE_SSL_REDIRECT`.

Django 2.1.9 release notes

June 3, 2019

Django 2.1.9 fixes security issues in 2.1.8.

CVE-2019-12308: AdminURLFieldWidget XSS

The clickable “Current URL” link generated by `AdminURLFieldWidget` displayed the provided value without validating it as a safe URL. Thus, an unvalidated value stored in the database, or a value provided as a URL query parameter payload, could result in an clickable JavaScript link.

`AdminURLFieldWidget` now validates the provided value using `URLValidator` before displaying the clickable link. You may customize the validator by passing a `validator_class` kwarg to `AdminURLFieldWidget.__init__()`, e.g. when using `formfield_overrides`.

Patched bundled jQuery for CVE-2019-11358: Prototype pollution

jQuery before 3.4.0, mishandles `jQuery.extend(true, {}, ...)` because of `Object.prototype` pollution. If an unsanitized source object contained an enumerable `__proto__` property, it could extend the native `Object.prototype`.

The bundled version of jQuery used by the Django admin has been patched to allow for the `select2` library's use of `jQuery.extend()`.

Django 2.1.8 release notes

April 1, 2019

Django 2.1.8 fixes a bug in 2.1.7.

Bugfixes

- Prevented admin inlines for a `ManyToManyField`'s implicit through model from being editable if the user only has the view permission ([#30289](#)).

Django 2.1.7 release notes

February 11, 2019

Django 2.1.7 fixes a packaging error in 2.1.6.

Bugfixes

- Corrected packaging error from 2.1.6 ([#30175](#)).

Django 2.1.6 release notes

February 11, 2019

Django 2.1.6 fixes a security issue and a bug in 2.1.5.

CVE-2019-6975: Memory exhaustion in `django.utils.numberformat.format()`

If `django.utils.numberformat.format()` –used by `contrib.admin` as well as the `floatformat`, `filesizeformat`, and `intcomma` templates filters –received a `Decimal` with a large number of digits or a large exponent, it could lead to significant memory usage due to a call to `'{:f}'.format()`.

To avoid this, decimals with more than 200 digits are now formatted using scientific notation.

Bugfixes

- Made the `obj` argument of `InlineModelAdmin.has_add_permission()` optional to restore backwards compatibility with third-party code that doesn't provide it (#30097).

Django 2.1.5 release notes

January 4, 2019

Django 2.1.5 fixes a security issue and several bugs in 2.1.4.

CVE-2019-3498: Content spoofing possibility in the default 404 page

An attacker could craft a malicious URL that could make spoofed content appear on the default page generated by the `django.views.defaults.page_not_found()` view.

The URL path is no longer displayed in the default 404 template and the `request_path` context variable is now quoted to fix the issue for custom templates that use the path.

Bugfixes

- Fixed compatibility with `mysqlclient` 1.3.14 (#30013).
- Fixed a schema corruption issue on SQLite 3.26+. You might have to drop and rebuild your SQLite database if you applied a migration while using an older version of Django with SQLite 3.26 or later (#29182).
- Prevented SQLite schema alterations while foreign key checks are enabled to avoid the possibility of schema corruption (#30023).
- Fixed a regression in Django 2.1.4 (which enabled keep-alive connections) where request body data isn't properly consumed for such connections (#30015).
- Fixed a regression in Django 2.1.4 where `InlineModelAdmin.has_change_permission()` is incorrectly called with a non-None `obj` argument during an object add (#30050).

Django 2.1.4 release notes

December 3, 2018

Django 2.1.4 fixes several bugs in 2.1.3.

Bugfixes

- Corrected the default password list that `CommonPasswordValidator` uses by lowercasing all passwords to match the format expected by the validator ([#29952](#)).
- Prevented repetitive calls to `geos_version_tuple()` in the `WKBWriter` class in an attempt to fix a random crash involving `LooseVersion` ([#29959](#)).
- Fixed keep-alive support in `runserver` after it was disabled to fix another issue in Django 2.0 ([#29849](#)).
- Fixed admin view-only change form crash when using `ModelAdmin.prepopulated_fields` ([#29929](#)).
- Fixed “Please correct the errors below” error message when editing an object in the admin if the user only has the “view” permission on inlines ([#29930](#)).

Django 2.1.3 release notes

November 1, 2018

Django 2.1.3 fixes several bugs in 2.1.2.

Bugfixes

- Fixed a regression in Django 2.0 where combining Q objects with `__in` lookups and lists crashed ([#29838](#)).
- Fixed a regression in Django 1.11 where `django-admin shell` may hang on startup ([#29774](#)).
- Fixed a regression in Django 2.0 where test databases aren’t reused with `manage.py test --keepdb` on MySQL ([#29827](#)).
- Fixed a regression where cached foreign keys that use `to_field` were incorrectly cleared in `Model.save()` ([#29896](#)).
- Fixed a regression in Django 2.0 where `FileSystemStorage` crashes with `FileExistsError` if concurrent saves try to create the same directory ([#29890](#)).

Django 2.1.2 release notes

October 1, 2018

Django 2.1.2 fixes a security issue and several bugs in 2.1.1. Also, the latest string translations from Transifex are incorporated.

CVE-2018-16984: Password hash disclosure to “view only” admin users

If an admin user has the change permission to the user model, only part of the password hash is displayed in the change form. Admin users with the view (but not change) permission to the user model were displayed the entire hash. While it’s typically infeasible to reverse a strong password hash, if your site uses weaker password hashing algorithms such as MD5 or SHA1, it could be a problem.

Bugfixes

- Fixed a regression where nonexistent joins in `F()` no longer raised `FieldError` (#29727).
- Fixed a regression where files starting with a tilde or underscore weren’t ignored by the migrations loader (#29749).
- Made migrations detect changes to `Meta.default_related_name` (#29755).
- Added compatibility for `cx_Oracle` 7 (#29759).
- Fixed a regression in Django 2.0 where unique index names weren’t quoted (#29778).
- Fixed a regression where sliced queries with multiple columns with the same name crashed on Oracle 12.1 (#29630).
- Fixed a crash when a user with the view (but not change) permission made a POST request to an admin user change form (#29809).

Django 2.1.1 release notes

August 31, 2018

Django 2.1.1 fixes several bugs in 2.1.

Bugfixes

- Fixed a race condition in `QuerySet.update_or_create()` that could result in data loss (#29499).
- Fixed a regression where `QueryDict.urlencode()` crashed if the dictionary contains a non-string value (#29627).
- Fixed a regression in Django 2.0 where using `manage.py test --keepdb` fails on PostgreSQL if the database exists and the user doesn't have permission to create databases (#29613).
- Fixed a regression in Django 2.0 where combining Q objects with `__in` lookups and lists crashed (#29643).
- Fixed translation failure of `DurationField`'s "overflow" error message (#29623).
- Fixed a regression where the admin change form crashed if the user doesn't have the 'add' permission to a model that uses `TabularInline` (#29637).
- Fixed a regression where a `related_query_name` reverse accessor wasn't set up when a `GenericRelation` is declared on an abstract base model (#29653).
- Fixed the test client's JSON serialization of a request data dictionary for structured content type suffixes (#29662).
- Made the admin change view redirect to the changelist view after a POST if the user has the 'view' permission (#29663).
- Fixed admin change view crash for view-only users if the form has an extra form field (#29682).
- Fixed a regression in Django 2.0.5 where `QuerySet.values()` or `values_list()` after combining querysets with `extra()` with `union()`, `difference()`, or `intersection()` crashed due to mismatching columns (#29694).
- Fixed crash if `InlineModelAdmin.has_add_permission()` doesn't accept the `obj` argument (#29723).

Django 2.1 release notes

August 1, 2018

Welcome to Django 2.1!

These release notes cover the [new features](#), as well as some [backwards incompatible changes](#) you'll want to be aware of when upgrading from Django 2.0 or earlier. We've [dropped some features](#) that have reached the end of their deprecation cycle, and we've [begun the deprecation process for some features](#).

See the [How to upgrade Django to a newer version](#) guide if you're updating an existing project.

Python compatibility

Django 2.1 supports Python 3.5, 3.6, and 3.7. Django 2.0 is the last version to support Python 3.4. We highly recommend and only officially support the latest release of each series.

What’s new in Django 2.1

Model “view” permission

A “view” permission is added to the model *Meta.default_permissions*. The new permissions will be created automatically when running *migrate*.

This allows giving users read-only access to models in the admin. *ModelAdmin.has_view_permission()* is new. The implementation is backwards compatible in that there isn’t a need to assign the “view” permission to allow users who have the “change” permission to edit objects.

There are a couple of [backwards incompatible considerations](#).

Minor features

`django.contrib.admin`

- *ModelAdmin.search_fields* now accepts any lookup such as `field__exact`.
- jQuery is upgraded from version 2.2.3 to 3.3.1.
- The new *ModelAdmin.delete_queryset()* method allows customizing the deletion process of the “delete selected objects” action.
- You can now [override the default admin site](#).
- The new *ModelAdmin.sortable_by* attribute and *ModelAdmin.get_sortable_by()* method allow limiting the columns that can be sorted in the change list page.
- The `admin_order_field` attribute for elements in *ModelAdmin.list_display* may now be a query expression.
- The new *ModelAdmin.get_deleted_objects()* method allows customizing the deletion process of the delete view and the “delete selected” action.
- The `actions.html`, `change_list_results.html`, `date_hierarchy.html`, `pagination.html`, `prepopulated_fields_js.html`, `search_form.html`, and `submit_line.html` templates can now be [overridden per app or per model](#) (besides overridden globally).
- The admin change list and change form object tools can now be [overridden per app, per model, or globally](#) with `change_list_object_tools.html` and `change_form_object_tools.html` templates.

- `InlineModelAdmin.has_add_permission()` is now passed the parent object as the second positional argument, `obj`.
- Admin actions may now `specify permissions` to limit their availability to certain users.

`django.contrib.auth`

- `createsuperuser` now gives a prompt to allow bypassing the `AUTH_PASSWORD_VALIDATORS` checks.

`django.contrib.gis`

- The new `GEOSGeometry.buffer_with_style()` method is a version of `buffer()` that allows customizing the style of the buffer.
- `OpenLayersWidget` is now based on OpenLayers 4.6.5 (previously 3.20.1).

`django.contrib.sessions`

- Added the `SESSION_COOKIE_SAMESITE` setting to set the `SameSite` cookie flag on session cookies.

Cache

- The `local-memory cache backend` now uses a least-recently-used (LRU) culling strategy rather than a pseudo-random one.
- The new `touch()` method of the `low-level cache API` updates the timeout of cache keys.

CSRF

- Added the `CSRF_COOKIE_SAMESITE` setting to set the `SameSite` cookie flag on CSRF cookies.

Forms

- The widget for `ImageField` now renders with the HTML attribute `accept="image/*"`.

Internationalization

- Added the `get_supported_language_variant()` function.
- Untranslated strings for territorial language variants now use the translations of the generic language. For example, untranslated `pt_BR` strings use `pt` translations.

Management Commands

- The new `inspectdb --include-views` option allows creating models for database views.
- The `BaseCommand` class now uses a custom help formatter so that the standard options like `--verbosity` or `--settings` appear last in the help output, giving a more prominent position to subclassed command's options.

Migrations

- Added support for serialization of `functools.partialmethod` objects.
- To support frozen environments, migrations may be loaded from `.pyc` files.

Models

- Models can now use `__init_subclass__()` from [PEP 487](#).
- A `BinaryField` may now be set to `editable=True` if you wish to include it in model forms.
- A number of new text database functions are added: `Chr`, `Left`, `LPad`, `LTrim`, `Ord`, `Repeat`, `Replace`, `Right`, `RPad`, `RTrim`, and `Trim`.
- The new `TruncWeek` function truncates `DateField` and `DateTimeField` to the Monday of a week.
- Query expressions can now be negated using a minus sign.
- `QuerySet.order_by()` and `distinct(*fields)` now support using field transforms.
- `BooleanField` can now be `null=True`. This is encouraged instead of `NullBooleanField`, which will likely be deprecated in the future.
- The new `QuerySet.explain()` method displays the database's execution plan of a queryset's query.
- `QuerySet.raw()` now supports `prefetch_related()`.

Requests and Responses

- Added `HttpRequest.get_full_path_info()`.
- Added the `samesite` argument to `HttpResponse.set_cookie()` to allow setting the `SameSite` cookie flag.
- The new `as_attachment` argument for `FileResponse` sets the `Content-Disposition` header to make the browser ask if the user wants to download the file. `FileResponse` also tries to set the `Content-Type` and `Content-Length` headers where appropriate.

Templates

- The new `json_script` filter safely outputs a Python object as JSON, wrapped in a `<script>` tag, ready for use with JavaScript.

Tests

- Added test `Client` support for 307 and 308 redirects.
- The test `Client` now serializes a request data dictionary as JSON if `content_type='application/json'`. You can customize the JSON encoder with test client's `json_encoder` parameter.
- The new `SimpleTestCase.assertWarnsMessage()` method is a simpler version of `assertWarnsRegex()`.

Backwards incompatible changes in 2.1

Database backend API

This section describes changes that may be needed in third-party database backends.

- To adhere to [PEP 249](#), exceptions where a database doesn't support a feature are changed from `NotImplementedError` to `django.db.NotSupportedError`.
- Renamed the `allow_sliced_subqueries` database feature flag to `allow_sliced_subqueries_with_in`.
- `DatabaseOperations.distinct_sql()` now requires an additional `params` argument and returns a tuple of SQL and parameters instead of an SQL string.
- `DatabaseFeatures.introspected_boolean_field_type` is changed from a method to a property.

`django.contrib.gis`

- Support for SpatiaLite 4.0 is removed.

Dropped support for MySQL 5.5

The end of upstream support for MySQL 5.5 is December 2018. Django 2.1 supports MySQL 5.6 and higher.

Dropped support for PostgreSQL 9.3

The end of upstream support for PostgreSQL 9.3 is September 2018. Django 2.1 supports PostgreSQL 9.4 and higher.

Removed BCryptPasswordHasher from the default `PASSWORD_HASHERS` setting

If you used `bcrypt` with Django 1.4 or 1.5 (before `BCryptSHA256PasswordHasher` was added in Django 1.6), you might have some passwords that use the `BCryptPasswordHasher` hasher.

You can check if that's the case like this:

```
from django.contrib.auth import get_user_model

User = get_user_model()
User.objects.filter(password__startswith="bcrypt$")
```

If you want to continue to allow those passwords to be used, you'll have to define the `PASSWORD_HASHERS` setting (if you don't already) and include `'django.contrib.auth.hashers.BCryptPasswordHasher'`.

Moved `wrap_label` widget template context variable

To fix the lack of `<label>` when using `RadioSelect` and `CheckboxSelectMultiple` with `MultiWidget`, the `wrap_label` context variable now appears as an attribute of each option. For example, in a custom `input_option.html` template, change `{% if wrap_label %}` to `{% if widget.wrap_label %}`.

SameSite cookies

The cookies used for `django.contrib.sessions`, `django.contrib.messages`, and Django’s CSRF protection now set the SameSite flag to Lax by default. Browsers that respect this flag won’t send these cookies on cross-origin requests. If you rely on the old behavior, set the `SESSION_COOKIE_SAMESITE` and/or `CSRF_COOKIE_SAMESITE` setting to None.

Considerations for the new model “view” permission

Custom admin forms need to take the view-only case into account

With the new “view” permission, existing custom admin forms may raise errors when a user doesn’t have the change permission because the form might access nonexistent fields. Fix this by overriding `ModelAdmin.get_form()` and checking if the user has the “change” permissions and returning the default form if not:

```
class MyAdmin(admin.ModelAdmin):
    def get_form(self, request, obj=None, **kwargs):
        if not self.has_change_permission(request, obj):
            return super().get_form(request, obj, **kwargs)
        return CustomForm
```

New default view permission could allow unwanted access to admin views

If you have a custom permission with a codename of the form `view_<modelname>`, the new view permission handling in the admin will allow view access to the changelist and detail pages for those models. If this is unwanted, you must change your custom permission codename.

Miscellaneous

- The minimum supported version of `mysqlclient` is increased from 1.3.3 to 1.3.7.
- Support for SQLite < 3.7.15 is removed.
- The date format of Set-Cookie’s Expires directive is changed to follow [RFC 7231#section-7.1.1.1](#) instead of Netscape’s cookie standard. Hyphens present in dates like Tue, 25-Dec-2018 22:26:13 GMT are removed. This change should be merely cosmetic except perhaps for antiquated browsers that don’t parse the new format.
- `allowed_hosts` is now a required argument of private API `django.utils.http.is_safe_url()`.
- The multiple attribute rendered by the `SelectMultiple` widget now uses HTML5 boolean syntax rather than XHTML’s `multiple="multiple"`.

- HTML rendered by form widgets no longer includes a closing slash on void elements, e.g. `<br>`. This is incompatible within XHTML, although some widgets already used aspects of HTML5 such as boolean attributes.
- The value of `SelectDateWidget`'s empty options is changed from 0 to an empty string, which mainly may require some adjustments in tests that compare HTML.
- `User.has_usable_password()` and the `is_password_usable()` function no longer return `False` if the password is `None` or an empty string, or if the password uses a hasher that's not in the `PASSWORD_HASHERS` setting. This undocumented behavior was a regression in Django 1.6 and prevented users with such passwords from requesting a password reset. Audit your code to confirm that your usage of these APIs don't rely on the old behavior.
- Since migrations are now loaded from `.pyc` files, you might need to delete them if you're working in a mixed Python 2 and Python 3 environment.
- Using `None` as a `django.contrib.postgres.fields.JSONField` lookup value now matches objects that have the specified key and a null value rather than objects that don't have the key.
- The admin CSS class `field-box` is renamed to `fieldBox` to prevent conflicts with the class given to model fields named "box".
- Since the admin's `actions.html`, `change_list_results.html`, `date_hierarchy.html`, `pagination.html`, `prepopulated_fields_js.html`, `search_form.html`, and `submit_line.html` templates can now be overridden per app or per model, you may need to rename existing templates with those names that were written for a different purpose.
- `QuerySet.raw()` now caches its results like regular queriesets. Use `iterator()` if you don't want caching.
- The database router `allow_relation()` method is called in more cases. Improperly written routers may need to be updated accordingly.
- Translations are no longer deactivated before running management commands. If your custom command requires translations to be deactivated (for example, to insert untranslated content into the database), use the new `@no_translations` decorator.
- Management commands no longer allow the abbreviated forms of the `--settings` and `--pythonpath` arguments.
- The private `django.db.models.sql.constants.QUERY_TERMS` constant is removed. The `get_lookup()` and `get_lookups()` methods of the [Lookup Registration API](#) may be suitable alternatives. Compared to the `QUERY_TERMS` constant, they allow your code to also account for any custom lookups that have been registered.
- Compatibility with `py-bcrypt` is removed as it's unmaintained. Use `bcrypt` instead.

Features deprecated in 2.1

Miscellaneous

- The `ForceRHR` GIS function is deprecated in favor of the new *`ForcePolygonCW`* function.
- `django.utils.http.cookie_date()` is deprecated in favor of *`http_date()`*, which follows the format of the latest RFC.
- `{% load staticfiles %}` and `{% load admin_static %}` are deprecated in favor of `{% load static %}`, which works the same.
- `django.contrib.staticfiles.templatetags.static()` is deprecated in favor of `django.templatetags.static.static()`.
- Support for *`InlineModelAdmin.has_add_permission()`* methods that don't accept `obj` as the second positional argument will be removed in Django 3.0.

Features removed in 2.1

These features have reached the end of their deprecation cycle and are removed in Django 2.1. See [Features deprecated in 1.11](#) for details, including how to remove usage of these features.

- `contrib.auth.views.login()`, `logout()`, `password_change()`, `password_change_done()`, `password_reset()`, `password_reset_done()`, `password_reset_confirm()`, and `password_reset_complete()` are removed.
- The `extra_context` parameter of `contrib.auth.views.logout_then_login()` is removed.
- `django.test.runner.setup_databases()` is removed.
- `django.utils.translation.string_concat()` is removed.
- `django.core.cache.backends.memcached.PyLibMCCache` no longer supports passing `pylibmc` behavior settings as top-level attributes of `OPTIONS`.
- The `host` parameter of `django.utils.http.is_safe_url()` is removed.
- Silencing of exceptions raised while rendering the `{% include %}` template tag is removed.
- `DatabaseIntrospection.get_indexes()` is removed.
- The `authenticate()` method of authentication backends requires `request` as the first positional argument.
- The `django.db.models.permlink()` decorator is removed.
- The `USE_ETAGS` setting is removed. `CommonMiddleware` and `django.utils.cache.patch_response_headers()` no longer set ETags.
- The `Model._meta.has_auto_field` attribute is removed.

- `url()`'s support for inline flags in regular expression groups `((?i)`, `(?L)`, `(?m)`, `(?s)`, and `(?u))` is removed.
- Support for `Widget.render()` methods without the `renderer` argument is removed.

9.1.9 2.0 release

Django 2.0.13 release notes

February 12, 2019

Django 2.0.13 fixes a regression in 2.0.12/2.0.11.

Bugfixes

- Fixed crash in `django.utils.numberformat.format_number()` when the number has over 200 digits ([#30177](#)).

Django 2.0.12 release notes

February 11, 2019

Django 2.0.12 fixes a packaging error in 2.0.11.

Bugfixes

- Corrected packaging error from 2.0.11 ([#30175](#)).

Django 2.0.11 release notes

February 11, 2019

Django 2.0.11 fixes a security issue in 2.0.10.

CVE-2019-6975: Memory exhaustion in `django.utils.numberformat.format()`

If `django.utils.numberformat.format()` –used by `contrib.admin` as well as the `floatformat`, `filesizeformat`, and `intcomma` templates filters –received a `Decimal` with a large number of digits or a large exponent, it could lead to significant memory usage due to a call to `'{:f}'.format()`.

To avoid this, decimals with more than 200 digits are now formatted using scientific notation.

Django 2.0.10 release notes

January 4, 2019

Django 2.0.10 fixes a security issue and several bugs in 2.0.9.

CVE-2019-3498: Content spoofing possibility in the default 404 page

An attacker could craft a malicious URL that could make spoofed content appear on the default page generated by the `django.views.defaults.page_not_found()` view.

The URL path is no longer displayed in the default 404 template and the `request_path` context variable is now quoted to fix the issue for custom templates that use the path.

Bugfixes

- Prevented repetitive calls to `geos_version_tuple()` in the `WKBWriter` class in an attempt to fix a random crash involving `LooseVersion` since Django 2.0.6 ([#29959](#)).
- Fixed a schema corruption issue on SQLite 3.26+. You might have to drop and rebuild your SQLite database if you applied a migration while using an older version of Django with SQLite 3.26 or later ([#29182](#)).
- Prevented SQLite schema alterations while foreign key checks are enabled to avoid the possibility of schema corruption ([#30023](#)).

Django 2.0.9 release notes

October 1, 2018

Django 2.0.9 fixes a data loss bug in 2.0.8.

Bugfixes

- Fixed a race condition in `QuerySet.update_or_create()` that could result in data loss ([#29499](#)).

Django 2.0.8 release notes

August 1, 2018

Django 2.0.8 fixes a security issue and several bugs in 2.0.7.

CVE-2018-14574: Open redirect possibility in `CommonMiddleware`

If the `CommonMiddleware` and the `APPEND_SLASH` setting are both enabled, and if the project has a URL pattern that accepts any path ending in a slash (many content management systems have such a pattern), then a request to a maliciously crafted URL of that site could lead to a redirect to another site, enabling phishing and other attacks.

`CommonMiddleware` now escapes leading slashes to prevent redirects to other domains.

Bugfixes

- Fixed a regression in Django 2.0.7 that broke the `regex` lookup on MariaDB (even though MariaDB isn't officially supported) (#29544).
- Fixed a regression where `django.template.Template` crashed if the `template_string` argument is lazy (#29617).

Django 2.0.7 release notes

July 2, 2018

Django 2.0.7 fixes several bugs in 2.0.6.

Bugfixes

- Fixed admin changelist crash when using a query expression without `asc()` or `desc()` in the page's ordering (#29428).
- Fixed admin check crash when using a query expression in `ModelAdmin.ordering` (#29428).
- Fixed `__regex` and `__iregex` lookups with MySQL 8 (#29451).
- Fixed migrations crash with namespace packages on Python 3.7 (#28814).

Django 2.0.6 release notes

June 1, 2018

Django 2.0.6 fixes several bugs in 2.0.5.

Bugfixes

- Fixed a regression that broke custom template filters that use decorators ([#29400](#)).
- Fixed detection of custom URL converters in included patterns ([#29415](#)).
- Fixed a regression that added an unnecessary subquery to the GROUP BY clause on MySQL when using a RawSQL annotation ([#29416](#)).
- Fixed WKBWriter.write() and write_hex() for empty polygons on GEOS 3.6.1+ ([#29460](#)).
- Fixed a regression in Django 1.10 that could result in large memory usage when making edits using ModelAdmin.list_editable ([#28462](#)).

Django 2.0.5 release notes

May 1, 2018

Django 2.0.5 fixes several bugs in 2.0.4.

Bugfixes

- Corrected the import paths that inspectdb generates for django.contrib.postgres fields ([#29307](#)).
- Fixed a regression in Django 1.11.8 where altering a field with a unique constraint may drop and rebuild more foreign keys than necessary ([#29193](#)).
- Fixed crashes in django.contrib.admindocs when a view is a callable object, such as django.contrib.syndication.views.Feed ([#29296](#)).
- Fixed a regression in Django 2.0.4 where QuerySet.values() or values_list() after combining an annotated and unannotated queryset with union(), difference(), or intersection() crashed due to mismatching columns ([#29286](#)).

Django 2.0.4 release notes

April 2, 2018

Django 2.0.4 fixes several bugs in 2.0.3.

Bugfixes

- Fixed a crash when filtering with an `Exists()` annotation of a queryset containing a single field (#29195).
- Fixed admin autocomplete widget's translations for `zh-hans` and `zh-hant` languages (#29213).
- Corrected admin's autocomplete widget to add a space after custom classes (#29221).
- Fixed `PasswordResetConfirmView` crash when using a user model with a `UUIDField` primary key and the reset URL contains an encoded primary key value that decodes to an invalid UUID (#29206).
- Fixed a regression in Django 1.11.8 where combining two annotated `values_list()` querysets with `union()`, `difference()`, or `intersection()` crashed due to mismatching columns (#29229).
- Fixed a regression in Django 1.11 where an empty choice could be initially selected for the `SelectMultiple` and `CheckboxSelectMultiple` widgets (#29273).
- Fixed a regression in Django 2.0 where `OpenLayersWidget` deserialization ignored the widget map's SRID and assumed 4326 (WGS84) (#29116).

Django 2.0.3 release notes

March 6, 2018

Django 2.0.3 fixes two security issues and several bugs in 2.0.2. Also, the latest string translations from Transifex are incorporated.

CVE-2018-7536: Denial-of-service possibility in `urlize` and `urlizetrunc` template filters

The `django.utils.html.urlize()` function was extremely slow to evaluate certain inputs due to catastrophic backtracking vulnerabilities in two regular expressions. The `urlize()` function is used to implement the `urlize` and `urlizetrunc` template filters, which were thus vulnerable.

The problematic regular expressions are replaced with parsing logic that behaves similarly.

CVE-2018-7537: Denial-of-service possibility in `truncatechars_html` and `truncatewords_html` template filters

If `django.utils.text.Truncator`'s `chars()` and `words()` methods were passed the `html=True` argument, they were extremely slow to evaluate certain inputs due to a catastrophic backtracking vulnerability in a regular expression. The `chars()` and `words()` methods are used to implement the `truncatechars_html` and `truncatewords_html` template filters, which were thus vulnerable.

The backtracking problem in the regular expression is fixed.

Bugfixes

- Fixed a regression that caused sliced `QuerySet.distinct().order_by()` followed by `count()` to crash (#29108).
- Prioritized the datetime and time input formats without `%f` for the Thai locale to fix the admin time picker widget displaying “undefined” (#29109).
- Fixed crash with `QuerySet.order_by(Exists(...))` (#29118).
- Made `Q.deconstruct()` deterministic with multiple keyword arguments (#29125). You may need to modify `Q`'s in existing migrations, or accept an autogenerated migration.
- Fixed a regression where a `When()` expression with a list argument crashes (#29166).
- Fixed crash when using a `Window()` expression in a subquery (#29172).
- Fixed `AbstractBaseUser.normalize_username()` crash if the `username` argument isn't a string (#29176).

Django 2.0.2 release notes

February 1, 2018

Django 2.0.2 fixes a security issue and several bugs in 2.0.1.

CVE-2018-6188: Information leakage in `AuthenticationForm`

A regression in Django 1.11.8 made `AuthenticationForm` run its `confirm_login_allowed()` method even if an incorrect password is entered. This can leak information about a user, depending on what messages `confirm_login_allowed()` raises. If `confirm_login_allowed()` isn't overridden, an attacker enter an arbitrary username and see if that user has been set to `is_active=False`. If `confirm_login_allowed()` is overridden, more sensitive details could be leaked.

This issue is fixed with the caveat that `AuthenticationForm` can no longer raise the “This account is inactive.” error if the authentication backend rejects inactive users (the default authentication backend, `ModelBackend`,

has done that since Django 1.10). This issue will be revisited for Django 2.1 as a fix to address the caveat will likely be too invasive for inclusion in older versions.

Bugfixes

- Fixed hidden content at the bottom of the “The install worked successfully!” page for some languages (#28885).
- Fixed incorrect foreign key nullification if a model has two foreign keys to the same model and a target model is deleted (#29016).
- Fixed regression in the use of `QuerySet.values_list(..., flat=True)` followed by `annotate()` (#29067).
- Fixed a regression where a queryset that annotates with geometry objects crashes (#29054).
- Fixed a regression where `contrib.auth.authenticate()` crashes if an authentication backend doesn't accept `request` and a later one does (#29071).
- Fixed a regression where `makemigrations` crashes if a migrations directory doesn't have an `__init__.py` file (#29091).
- Fixed crash when entering an invalid uuid in `ModelAdmin.raw_id_fields` (#29094).

Django 2.0.1 release notes

January 1, 2018

Django 2.0.1 fixes several bugs in 2.0.

Bugfixes

- Fixed a regression in Django 1.11 that added newlines between `MultiWidget`'s subwidgets (#28890).
- Fixed incorrect class-based model index name generation for models with quoted `db_table` (#28876).
- Fixed incorrect foreign key constraint name for models with quoted `db_table` (#28876).
- Fixed a regression in caching of a `GenericForeignKey` when the referenced model instance uses more than one level of multi-table inheritance (#28856).
- Reallowed filtering a queryset with `GeometryField=None` (#28896).
- Corrected admin check to allow a `OneToOneField` in `ModelAdmin.autocomplete_fields` (#28898).
- Fixed a regression on SQLite where `DecimalField` returned a result with trailing zeros in the fractional part truncated (#28915).
- Fixed crash in the `testserver` command startup (#28941).

- Fixed crash when coercing a translatable URL pattern to `str` (#28947).
- Fixed crash on SQLite when renaming a field in a model referenced by a `ManyToManyField` (#28884).
- Fixed a crash when chaining `values()` or `values_list()` after `QuerySet.select_for_update(of=(. . .))` (#28944).
- Fixed admin changelist crash when using a query expression in the page's ordering (#28958).

Django 2.0 release notes

December 2, 2017

Welcome to Django 2.0!

These release notes cover the [new features](#), as well as some [backwards incompatible changes](#) you'll want to be aware of when upgrading from Django 1.11 or earlier. We've [dropped some features](#) that have reached the end of their deprecation cycle, and we've [begun the deprecation process for some features](#).

This release starts Django's use of a [loose form of semantic versioning](#), but there aren't any major backwards incompatible changes that might be expected of a 2.0 release. Upgrading should be a similar amount of effort as past feature releases.

See the [How to upgrade Django to a newer version](#) guide if you're updating an existing project.

Python compatibility

Django 2.0 supports Python 3.4, 3.5, 3.6, and 3.7. We highly recommend and only officially support the latest release of each series.

The Django 1.11.x series is the last to support Python 2.7.

Django 2.0 will be the last release series to support Python 3.4. If you plan a deployment of Python 3.4 beyond the end-of-life for Django 2.0 (April 2019), stick with Django 1.11 LTS (supported until April 2020) instead. Note, however, that the end-of-life for Python 3.4 is March 2019.

Third-party library support for older version of Django

Following the release of Django 2.0, we suggest that third-party app authors drop support for all versions of Django prior to 1.11. At that time, you should be able to run your package's tests using `python -Wd` so that deprecation warnings do appear. After making the deprecation warning fixes, your app should be compatible with Django 2.0.

What's new in Django 2.0

Simplified URL routing syntax

The new `django.urls.path()` function allows a simpler, more readable URL routing syntax. For example, this example from previous Django releases:

```
url(r"^articles/(?P<year>[0-9]{4})/$", views.year_archive),
```

could be written as:

```
path("articles/<int:year>/", views.year_archive),
```

The new syntax supports type coercion of URL parameters. In the example, the view will receive the `year` keyword argument as an integer rather than as a string. Also, the URLs that will match are slightly less constrained in the rewritten example. For example, the year 10000 will now match since the year integers aren't constrained to be exactly four digits long as they are in the regular expression.

The `django.conf.urls.url()` function from previous versions is now available as `django.urls.re_path()`. The old location remains for backwards compatibility, without an imminent deprecation. The old `django.conf.urls.include()` function is now importable from `django.urls` so you can use `from django.urls import include, path, re_path` in your URLconfs.

The [URL dispatcher](#) document is rewritten to feature the new syntax and provide more details.

Mobile-friendly contrib.admin

The admin is now responsive and supports all major mobile devices. Older browsers may experience varying levels of graceful degradation.

Window expressions

The new *Window* expression allows adding an `OVER` clause to queriesets. You can use [window functions](#) and [aggregate functions](#) in the expression.

Minor features

`django.contrib.admin`

- The new `ModelAdmin.autocomplete_fields` attribute and `ModelAdmin.get_autocomplete_fields()` method allow using a [Select2](#) search widget for `ForeignKey` and `ManyToManyField`.

`django.contrib.auth`

- The default iteration count for the PBKDF2 password hasher is increased from 36,000 to 100,000.

`django.contrib.gis`

- Added MySQL support for the *AsGeoJSON* function, *GeoHash* function, *IsValid* function, *isvalid* lookup, and *distance* lookups.
- Added the *Azimuth* and *LineLocatePoint* functions, supported on PostGIS and SpatiaLite.
- Any *GEOSGeometry* imported from GeoJSON now has its SRID set.
- Added the *OSMWidget.default_zoom* attribute to customize the map's default zoom level.
- Made metadata readable and editable on rasters through the *metadata*, *info*, and *metadata* attributes.
- Allowed passing driver-specific creation options to *GDALRaster* objects using *papsz_options*.
- Allowed creating *GDALRaster* objects in GDAL's internal virtual filesystem. Rasters can now be created from and converted to binary data in-memory.
- The new *GDALBand.color_interp()* method returns the color interpretation for the band.

`django.contrib.postgres`

- The new *distinct* argument for *ArrayAgg* determines if concatenated values will be distinct.
- The new *RandomUUID* database function returns a version 4 UUID. It requires use of PostgreSQL's *pgcrypto* extension which can be activated using the new *CryptoExtension* migration operation.
- *django.contrib.postgres.indexes.GinIndex* now supports the *fastupdate* and *gin_pending_list_limit* parameters.
- The new *GistIndex* class allows creating GiST indexes in the database. The new *BtreeGistExtension* migration operation installs the *btree_gist* extension to add support for operator classes that aren't built-in.
- *inspectdb* can now introspect *JSONField* and various *RangeFields* (`django.contrib.postgres` must be in `INSTALLED_APPS`).

django.contrib.sitemaps

- Added the `protocol` keyword argument to the *GenericSitemap* constructor.

Cache

- `cache.set_many()` now returns a list of keys that failed to be inserted. For the built-in backends, failed inserts can only happen on memcached.

File Storage

- *File.open()* can be used as a context manager, e.g. with `file.open()` as `f`:

Forms

- The new `date_attrs` and `time_attrs` arguments for *SplitDateTimeWidget* and *SplitHiddenDateTimeWidget* allow specifying different HTML attributes for the `DateInput` and `TimeInput` (or `hidden`) subwidgets.
- The new *Form.errors.get_json_data()* method returns form errors as a dictionary suitable for including in a JSON response.

Generic Views

- The new *ContextMixin.extra_context* attribute allows adding context in `View.as_view()`.

Management Commands

- *inspectdb* now translates MySQL's unsigned integer columns to `PositiveIntegerField` or `PositiveSmallIntegerField`.
- The new *makemessages --add-location* option controls the comment format in `.po` files.
- *loaddata* can now read from `stdin`.
- The new *diffsettings --output* option allows formatting the output in a unified diff format.
- On Oracle, *inspectdb* can now introspect `AutoField` if the column is created as an identity column.
- On MySQL, *dbshell* now supports client-side TLS certificates.

Migrations

- The new `squashmigrations --squashed-name` option allows naming the squashed migration.

Models

- The new `StrIndex` database function finds the starting index of a string inside another string.
- On Oracle, `AutoField` and `BigAutoField` are now created as `identity columns`.
- The new `chunk_size` parameter of `QuerySet.iterator()` controls the number of rows fetched by the Python database client when streaming results from the database. For databases that don't support server-side cursors, it controls the number of results Django fetches from the database adapter.
- `QuerySet.earliest()`, `QuerySet.latest()`, and `Meta.get_latest_by` now allow ordering by several fields.
- Added the `ExtractQuarter` function to extract the quarter from `DateField` and `DateTimeField`, and exposed it through the `quarter` lookup.
- Added the `TruncQuarter` function to truncate `DateField` and `DateTimeField` to the first day of a quarter.
- Added the `db_tablespace` parameter to class-based indexes.
- If the database supports a native duration field (Oracle and PostgreSQL), `Extract` now works with `DurationField`.
- Added the `of` argument to `QuerySet.select_for_update()`, supported on PostgreSQL and Oracle, to lock only rows from specific tables rather than all selected tables. It may be helpful particularly when `select_for_update()` is used in conjunction with `select_related()`.
- The new `field_name` parameter of `QuerySet.in_bulk()` allows fetching results based on any unique model field.
- `CursorWrapper.callproc()` now takes an optional dictionary of keyword parameters, if the backend supports this feature. Of Django's built-in backends, only Oracle supports it.
- The new `connection.execute_wrapper()` method allows installing wrappers around execution of database queries.
- The new `filter` argument for built-in aggregates allows adding different conditionals to multiple aggregations over the same fields or relations.
- Added support for expressions in `Meta.ordering`.
- The new `named` parameter of `QuerySet.values_list()` allows fetching results as named tuples.
- The new `FilteredRelation` class allows adding an `ON` clause to querysets.

Pagination

- Added `Paginator.get_page()` to provide the documented pattern of handling invalid page numbers.

Requests and Responses

- The `runserver` web server supports HTTP 1.1.

Templates

- To increase the usefulness of `Engine.get_default()` in third-party apps, it now returns the first engine if multiple `DjangoTemplates` engines are configured in `TEMPLATES` rather than raising `ImproperlyConfigured`.
- Custom template tags may now accept keyword-only arguments.

Tests

- Added threading support to `LiveServerTestCase`.
- Added settings that allow customizing the test tablespace parameters for Oracle: `DATAFILE_SIZE`, `DATAFILE_TMP_SIZE`, `DATAFILE_EXTSIZE`, and `DATAFILE_TMP_EXTSIZE`.

Validators

- The new `ProhibitNullCharactersValidator` disallows the null character in the input of the `CharField` form field and its subclasses. Null character input was observed from vulnerability scanning tools. Most databases silently discard null characters, but `psycopg2 2.7+` raises an exception when trying to save a null character to a char/text field with PostgreSQL.

Backwards incompatible changes in 2.0

Removed support for bytestrings in some places

To support native Python 2 strings, older Django versions had to accept both bytestrings and Unicode strings. Now that Python 2 support is dropped, bytestrings should only be encountered around input/output boundaries (handling of binary fields or HTTP streams, for example). You might have to update your code to limit bytestring usage to a minimum, as Django no longer accepts bytestrings in certain code paths. Python's `-b` option may help detect that mistake in your code.

For example, `reverse()` now uses `str()` instead of `force_text()` to coerce the `args` and `kwargs` it receives, prior to their placement in the URL. For bytestrings, this creates a string with an undesired `b` prefix as well

as additional quotes (`str(b'foo')` is `"b'foo'"`). To adapt, call `decode()` on the bytestring before passing it to `reverse()`.

Database backend API

This section describes changes that may be needed in third-party database backends.

- The `DatabaseOperations.datetime_cast_date_sql()`, `datetime_cast_time_sql()`, `datetime_trunc_sql()`, `datetime_extract_sql()`, and `date_interval_sql()` methods now return only the SQL to perform the operation instead of SQL and a list of parameters.
- Third-party database backends should add a `DatabaseWrapper.display_name` attribute with the name of the database that your backend works with. Django may use it in various messages, such as in system checks.
- The first argument of `SchemaEditor._alter_column_type_sql()` is now `model` rather than `table`.
- The first argument of `SchemaEditor._create_index_name()` is now `table_name` rather than `model`.
- To enable FOR UPDATE OF support, set `DatabaseFeatures.has_select_for_update_of = True`. If the database requires that the arguments to OF be columns rather than tables, set `DatabaseFeatures.select_for_update_of_column = True`.
- To enable support for *Window* expressions, set `DatabaseFeatures.supports_over_clause` to `True`. You may need to customize the `DatabaseOperations.window_start_rows_start_end()` and/or `window_start_range_start_end()` methods.
- Third-party database backends should add a `DatabaseOperations.cast_char_field_without_max_length` attribute with the database data type that will be used in the *Cast* function for a `CharField` if the `max_length` argument isn't provided.
- The first argument of `DatabaseCreation._clone_test_db()` and `get_test_db_clone_settings()` is now `suffix` rather than `number` (in case you want to rename the signatures in your backend for consistency). `django.test` also now passes those values as strings rather than as integers.
- Third-party database backends should add a `DatabaseIntrospection.get_sequences()` method based on the stub in `BaseDatabaseIntrospection`.

Dropped support for Oracle 11.2

The end of upstream support for Oracle 11.2 is Dec. 2020. Django 1.11 will be supported until April 2020 which almost reaches this date. Django 2.0 officially supports Oracle 12.1+.

Default MySQL isolation level is read committed

MySQL's default isolation level, repeatable read, may cause data loss in typical Django usage. To prevent that and for consistency with other databases, the default isolation level is now read committed. You can use the `DATABASES` setting to use a different isolation level, if needed.

`AbstractUser.last_name` max_length increased to 150

A migration for `django.contrib.auth.models.User.last_name` is included. If you have a custom user model inheriting from `AbstractUser`, you'll need to generate and apply a database migration for your user model.

If you want to preserve the 30 character limit for last names, use a custom form:

```
from django.contrib.auth.forms import UserChangeForm

class MyUserChangeForm(UserChangeForm):
    last_name = forms.CharField(max_length=30, required=False)
```

If you wish to keep this restriction in the admin when editing users, set `UserAdmin.form` to use this form:

```
from django.contrib.auth.admin import UserAdmin
from django.contrib.auth.models import User

class MyUserAdmin(UserAdmin):
    form = MyUserChangeForm

admin.site.unregister(User)
admin.site.register(User, MyUserAdmin)
```

`QuerySet.reverse()` and `last()` are prohibited after slicing

Calling `QuerySet.reverse()` or `last()` on a sliced queryset leads to unexpected results due to the slice being applied after reordering. This is now prohibited, e.g.:

```
>>> Model.objects.all()[:2].reverse()
Traceback (most recent call last):
...
TypeError: Cannot reverse a query once a slice has been taken.
```

Form fields no longer accept optional arguments as positional arguments

To help prevent runtime errors due to incorrect ordering of form field arguments, optional arguments of built-in form fields are no longer accepted as positional arguments. For example:

```
forms.IntegerField(25, 10)
```

raises an exception and should be replaced with:

```
forms.IntegerField(max_value=25, min_value=10)
```

call_command() validates the options it receives

call_command() now validates that the argument parser of the command being called defines all of the options passed to call_command().

For custom management commands that use options not created using parser.add_argument(), add a stealth_options attribute on the command:

```
class MyCommand(BaseCommand):
    stealth_options = ("option_name", ...)
```

Indexes no longer accept positional arguments

For example:

```
models.Index(["headline", "-pub_date"], "index_name")
```

raises an exception and should be replaced with:

```
models.Index(fields=["headline", "-pub_date"], name="index_name")
```

Foreign key constraints are now enabled on SQLite

This will appear as a backwards-incompatible change (IntegrityError: FOREIGN KEY constraint failed) if attempting to save an existing model instance that's violating a foreign key constraint.

Foreign keys are now created with DEFERRABLE INITIALLY DEFERRED instead of DEFERRABLE IMMEDIATE. Thus, tables may need to be rebuilt to recreate foreign keys with the new definition, particularly if you're using a pattern like this:

```
from django.db import transaction

with transaction.atomic():
    Book.objects.create(author_id=1)
    Author.objects.create(id=1)
```

If you don't recreate the foreign key as DEFERRED, the first `create()` would fail now that foreign key constraints are enforced.

Backup your database first! After upgrading to Django 2.0, you can then rebuild tables using a script similar to this:

```
from django.apps import apps
from django.db import connection

for app in apps.get_app_configs():
    for model in app.get_models(include_auto_created=True):
        if model._meta.managed and not (model._meta.proxy or model._meta.swapped):
            for base in model.__bases__:
                if hasattr(base, "_meta"):
                    base._meta.local_many_to_many = []
            model._meta.local_many_to_many = []
            with connection.schema_editor() as editor:
                editor._remake_table(model)
```

This script hasn't received extensive testing and needs adaption for various cases such as multiple databases. Feel free to contribute improvements.

In addition, because of a table alteration limitation of SQLite, it's prohibited to perform *RenameModel* and *RenameField* operations on models or fields referenced by other models in a transaction. In order to allow migrations containing these operations to be applied, you must set the `Migration.atomic` attribute to `False`.

Miscellaneous

- The `SessionAuthenticationMiddleware` class is removed. It provided no functionality since session authentication is unconditionally enabled in Django 1.10.
- The default HTTP error handlers (`handler404`, etc.) are now callables instead of dotted Python path strings. Django favors callable references since they provide better performance and debugging experience.
- *RedirectView* no longer silences `NoReverseMatch` if the `pattern_name` doesn't exist.
- When `USE_L10N` is off, *FloatField* and *DecimalField* now respect `DECIMAL_SEPARATOR` and `THOUSAND_SEPARATOR` during validation. For example, with the settings:

```
USE_L10N = False
USE_THOUSAND_SEPARATOR = True
DECIMAL_SEPARATOR = ","
THOUSAND_SEPARATOR = "."
```

an input of "1.345" is now converted to 1345 instead of 1.345.

- Subclasses of `AbstractBaseUser` are no longer required to implement `get_short_name()` and `get_full_name()`. (The base implementations that raise `NotImplementedError` are removed.) `django.contrib.admin` uses these methods if implemented but doesn't require them. Third-party apps that use these methods may want to adopt a similar approach.
- The `FIRST_DAY_OF_WEEK` and `NUMBER_GROUPING` format settings are now kept as integers in JavaScript and JSON `l10n` view outputs.
- `assertNumQueries()` now ignores connection configuration queries. Previously, if a test opened a new database connection, those queries could be included as part of the `assertNumQueries()` count.
- The default size of the Oracle test tablespace is increased from 20M to 50M and the default `autoextend` size is increased from 10M to 25M.
- To improve performance when streaming large result sets from the database, `QuerySet.iterator()` now fetches 2000 rows at a time instead of 100. The old behavior can be restored using the `chunk_size` parameter. For example:

```
Book.objects.iterator(chunk_size=100)
```

- Providing unknown package names in the `packages` argument of the `JavaScriptCatalog` view now raises `ValueError` instead of passing silently.
- A model instance's primary key now appears in the default `Model.__str__()` method, e.g. `Question object (1)`.
- `makemigrations` now detects changes to the model field `limit_choices_to` option. Add this to your existing migrations or accept an auto-generated migration for fields that use it.
- Performing queries that require `automatic spatial transformations` now raises `NotImplementedError` on MySQL instead of silently using non-transformed geometries.
- `django.core.exceptions.DjangoRuntimeWarning` is removed. It was only used in the cache backend as an intermediate class in `CacheKeyWarning`'s inheritance of `RuntimeWarning`.
- Renamed `BaseExpression._output_field` to `output_field`. You may need to update custom expressions.
- In older versions, forms and formsets combine their `Media` with widget `Media` by concatenating the two. The combining now tries to `preserve the relative order of elements in each list`. `MediaOrderConflictWarning` is issued if the order can't be preserved.

- `django.contrib.gis.gdal.OGREException` is removed. It's been an alias for `GDALException` since Django 1.8.
- Support for GEOS 3.3.x is dropped.
- The way data is selected for `GeometryField` is changed to improve performance, and in raw SQL queries, those fields must now be wrapped in `connection.ops.select`. See the [Raw queries note](#) in the GIS tutorial for an example.

Features deprecated in 2.0

context argument of `Field.from_db_value()` and `Expression.convert_value()`

The `context` argument of `Field.from_db_value()` and `Expression.convert_value()` is unused as it's always an empty dictionary. The signature of both methods is now:

```
(self, value, expression, connection)
```

instead of:

```
(self, value, expression, connection, context)
```

Support for the old signature in custom fields and expressions remains until Django 3.0.

Miscellaneous

- The `django.db.backends.postgresql_psycopg2` module is deprecated in favor of `django.db.backends.postgresql`. It's been an alias since Django 1.9. This only affects code that imports from the module directly. The `DATABASES` setting can still use `'django.db.backends.postgresql_psycopg2'`, though you can simplify that by using the `'django.db.backends.postgresql'` name added in Django 1.9.
- `django.shortcuts.render_to_response()` is deprecated in favor of `django.shortcuts.render()`. `render()` takes the same arguments except that it also requires a `request`.
- The `DEFAULT_CONTENT_TYPE` setting is deprecated. It doesn't interact well with third-party apps and is obsolete since HTML5 has mostly superseded XHTML.
- `HttpRequest.xreadlines()` is deprecated in favor of iterating over the request.
- The `field_name` keyword argument to `QuerySet.earliest()` and `QuerySet.latest()` is deprecated in favor of passing the field names as arguments. Write `.earliest('pub_date')` instead of `.earliest(field_name='pub_date')`.

Features removed in 2.0

These features have reached the end of their deprecation cycle and are removed in Django 2.0.

See [Features deprecated in 1.9](#) for details on these changes, including how to remove usage of these features.

- The `weak` argument to `django.dispatch.signals.Signal.disconnect()` is removed.
- `django.db.backends.base.BaseDatabaseOperations.check_aggregate_support()` is removed.
- The `django.forms.extras` package is removed.
- The `assignment_tag` helper is removed.
- The `host` argument to `SimpleTestCase.assertsRedirects()` is removed. The compatibility layer which allows absolute URLs to be considered equal to relative ones when the path is identical is also removed.
- `Field.rel` and `Field.remote_field.to` are removed.
- The `on_delete` argument for `ForeignKey` and `OneToOneField` is now required in models and migrations. Consider squashing migrations so that you have fewer of them to update.
- `django.db.models.fields.add_lazy_relation()` is removed.
- When time zone support is enabled, database backends that don't support time zones no longer convert aware datetimes to naive values in UTC anymore when such values are passed as parameters to SQL queries executed outside of the ORM, e.g. with `cursor.execute()`.
- `django.contrib.auth.tests.utils.skipIfCustomUser()` is removed.
- The `GeoManager` and `GeoQuerySet` classes are removed.
- The `django.contrib.gis.geoip` module is removed.
- The `supports_recursion` check for template loaders is removed from:
 - `django.template.engine.Engine.find_template()`
 - `django.template.loader_tags.ExtendsNode.find_template()`
 - `django.template.loaders.base.Loader.supports_recursion()`
 - `django.template.loaders.cached.Loader.supports_recursion()`
- The `load_template` and `load_template_sources` template loader methods are removed.
- The `template_dirs` argument for template loaders is removed:
 - `django.template.loaders.base.Loader.get_template()`
 - `django.template.loaders.cached.Loader.cache_key()`
 - `django.template.loaders.cached.Loader.get_template()`
 - `django.template.loaders.cached.Loader.get_template_sources()`

- `django.template.loaders.filesystem.Loader.get_template_sources()`
- `django.template.loaders.base.Loader.__call__()` is removed.
- Support for custom error views that don't accept an `exception` parameter is removed.
- The `mime_type` attribute of `django.utils.feedgenerator.Atom1Feed` and `django.utils.feedgenerator.RssFeed` is removed.
- The `app_name` argument to `include()` is removed.
- Support for passing a 3-tuple (including `admin.site.urls`) as the first argument to `include()` is removed.
- Support for setting a URL instance namespace without an application namespace is removed.
- `Field._get_val_from_obj()` is removed.
- `django.template.loaders.eggs.Loader` is removed.
- The `current_app` parameter to the `contrib.auth` function-based views is removed.
- The `callable_obj` keyword argument to `SimpleTestCase.assertRaisesMessage()` is removed.
- Support for the `allow_tags` attribute on `ModelAdmin` methods is removed.
- The `enclosure` keyword argument to `SyndicationFeed.add_item()` is removed.
- The `django.template.loader.LoaderOrigin` and `django.template.base.StringOrigin` aliases for `django.template.base.Origin` are removed.

See [Features deprecated in 1.10](#) for details on these changes.

- The `makemigrations --exit` option is removed.
- Support for direct assignment to a reverse foreign key or many-to-many relation is removed.
- The `get_srid()` and `set_srid()` methods of `django.contrib.gis.geos.GEOSGeometry` are removed.
- The `get_x()`, `set_x()`, `get_y()`, `set_y()`, `get_z()`, and `set_z()` methods of `django.contrib.gis.geos.Point` are removed.
- The `get_coords()` and `set_coords()` methods of `django.contrib.gis.geos.Point` are removed.
- The `cascaded_union` property of `django.contrib.gis.geos.MultiPolygon` is removed.
- `django.utils.functional.allow_lazy()` is removed.
- The `shell --plain` option is removed.
- The `django.core.urlresolvers` module is removed in favor of its new location, `django.urls`.
- `CommaSeparatedIntegerField` is removed, except for support in historical migrations.
- The `template.Context.has_key()` method is removed.
- Support for the `django.core.files.storage.Storage.accessed_time()`, `created_time()`, and `modified_time()` methods is removed.

- Support for query lookups using the model name when `Meta.default_related_name` is set is removed.
- The MySQL `__search` lookup is removed.
- The shim for supporting custom related manager classes without a `_apply_rel_filters()` method is removed.
- Using `User.is_authenticated()` and `User.is_anonymous()` as methods rather than properties is no longer supported.
- The `Model._meta.virtual_fields` attribute is removed.
- The keyword arguments `virtual_only` in `Field.contribute_to_class()` and `virtual` in `Model._meta.add_field()` are removed.
- The `javascript_catalog()` and `json_catalog()` views are removed.
- `django.contrib.gis.utils.precision_wkt()` is removed.
- In multi-table inheritance, implicit promotion of a `OneToOneField` to a `parent_link` is removed.
- Support for `Widget._format_value()` is removed.
- `FileField` methods `get_directory_name()` and `get_filename()` are removed.
- The `mark_for_escaping()` function and the classes it uses: `EscapeData`, `EscapeBytes`, `EscapeText`, `EscapeString`, and `EscapeUnicode` are removed.
- The escape filter now uses `django.utils.html.conditional_escape()`.
- `Manager.use_for_related_fields` is removed.
- Model `Manager` inheritance follows MRO inheritance rules. The requirement to use `Meta.manager_inheritance_from_future` to opt-in to the behavior is removed.
- Support for old-style middleware using `settings.MIDDLEWARE_CLASSES` is removed.

9.1.10 1.11 release

Django 1.11.29 release notes

March 4, 2020

Django 1.11.29 fixes a security issue in 1.11.28.

CVE-2020-9402: Potential SQL injection via `tolerance` parameter in GIS functions and aggregates on Oracle

GIS functions and aggregates on Oracle were subject to SQL injection, using a suitably crafted `tolerance`.

Django 1.11.28 release notes

February 3, 2020

Django 1.11.28 fixes a security issue in 1.11.27.

CVE-2020-7471: Potential SQL injection via `StringAgg(delimiter)`

StringAgg aggregation function was subject to SQL injection, using a suitably crafted `delimiter`.

Django 1.11.27 release notes

December 18, 2019

Django 1.11.27 fixes a security issue and a data loss bug in 1.11.26.

CVE-2019-19844: Potential account hijack via password reset form

By submitting a suitably crafted email address making use of Unicode characters, that compared equal to an existing user email when lower-cased for comparison, an attacker could be sent a password reset token for the matched account.

In order to avoid this vulnerability, password reset requests now compare the submitted email using the stricter, recommended algorithm for case-insensitive comparison of two identifiers from [Unicode Technical Report 36, section 2.11.2\(B\)\(2\)](#). Upon a match, the email containing the reset token will be sent to the email address on record rather than the submitted address.

Bugfixes

- Fixed a data loss possibility in *SplitArrayField*. When using with `ArrayField(BooleanField())`, all values after the first `True` value were marked as checked instead of preserving passed values ([#31073](#)).

Django 1.11.26 release notes

November 4, 2019

Django 1.11.26 fixes a regression in 1.11.25.

Bugfixes

- Fixed a crash when using a `contains`, `contained_by`, `has_key`, `has_keys`, or `has_any_keys` lookup on `django.contrib.postgres.fields.JSONField`, if the right or left hand side of an expression is a key transform ([#30826](#)).

Django 1.11.25 release notes

October 1, 2019

Django 1.11.25 fixes a regression in 1.11.23.

Bugfixes

- Fixed a crash when filtering with a `Subquery()` annotation of a queryset containing `django.contrib.postgres.fields.JSONField` or *HStoreField* ([#30769](#)).

Django 1.11.24 release notes

September 2, 2019

Django 1.11.24 fixes a regression in 1.11.23.

Bugfixes

- Fixed crash of `KeyTransform()` for `django.contrib.postgres.fields.JSONField` and *HStoreField* when using on expressions with params ([#30672](#)).

Django 1.11.23 release notes

August 1, 2019

Django 1.11.23 fixes security issues in 1.11.22.

CVE-2019-14232: Denial-of-service possibility in `django.utils.text.Truncator`

If `django.utils.text.Truncator`'s `chars()` and `words()` methods were passed the `html=True` argument, they were extremely slow to evaluate certain inputs due to a catastrophic backtracking vulnerability in a regular expression. The `chars()` and `words()` methods are used to implement the `truncatechars_html` and `truncatewords_html` template filters, which were thus vulnerable.

The regular expressions used by `Truncator` have been simplified in order to avoid potential backtracking issues. As a consequence, trailing punctuation may now at times be included in the truncated output.

CVE-2019-14233: Denial-of-service possibility in `strip_tags()`

Due to the behavior of the underlying `HTMLParser`, `django.utils.html.strip_tags()` would be extremely slow to evaluate certain inputs containing large sequences of nested incomplete HTML entities. The `strip_tags()` method is used to implement the corresponding `striptags` template filter, which was thus also vulnerable.

`strip_tags()` now avoids recursive calls to `HTMLParser` when progress removing tags, but necessarily incomplete HTML entities, stops being made.

Remember that absolutely NO guarantee is provided about the results of `strip_tags()` being HTML safe. So NEVER mark safe the result of a `strip_tags()` call without escaping it first, for example with `django.utils.html.escape()`.

CVE-2019-14234: SQL injection possibility in key and index lookups for `JSONField`/`HStoreField`

Key and index lookups for `django.contrib.postgres.fields.JSONField` and *key lookups* for `HStoreField` were subject to SQL injection, using a suitably crafted dictionary, with dictionary expansion, as the `**kwargs` passed to `QuerySet.filter()`.

CVE-2019-14235: Potential memory exhaustion in `django.utils.encoding.uri_to_iri()`

If passed certain inputs, `django.utils.encoding.uri_to_iri()` could lead to significant memory usage due to excessive recursion when re-percent-encoding invalid UTF-8 octet sequences.

`uri_to_iri()` now avoids recursion when re-percent-encoding invalid UTF-8 octet sequences.

Django 1.11.22 release notes

July 1, 2019

Django 1.11.22 fixes a security issue in 1.11.21.

CVE-2019-12781: Incorrect HTTP detection with reverse-proxy connecting via HTTPS

When deployed behind a reverse-proxy connecting to Django via HTTPS, `django.http.HttpRequest.scheme` would incorrectly detect client requests made via HTTP as using HTTPS. This entails incorrect results for `is_secure()`, and `build_absolute_uri()`, and that HTTP requests would not be redirected to HTTPS in accordance with `SECURE_SSL_REDIRECT`.

`HttpRequest.scheme` now respects `SECURE_PROXY_SSL_HEADER`, if it is configured, and the appropriate header is set on the request, for both HTTP and HTTPS requests.

If you deploy Django behind a reverse-proxy that forwards HTTP requests, and that connects to Django via HTTPS, be sure to verify that your application correctly handles code paths relying on `scheme`, `is_secure()`, `build_absolute_uri()`, and `SECURE_SSL_REDIRECT`.

Django 1.11.21 release notes

June 3, 2019

Django 1.11.21 fixes a security issue in 1.11.20.

CVE-2019-12308: AdminURLFieldWidget XSS

The clickable “Current URL” link generated by `AdminURLFieldWidget` displayed the provided value without validating it as a safe URL. Thus, an unvalidated value stored in the database, or a value provided as a URL query parameter payload, could result in an clickable JavaScript link.

`AdminURLFieldWidget` now validates the provided value using `URLValidator` before displaying the clickable link. You may customize the validator by passing a `validator_class` kwarg to `AdminURLFieldWidget.__init__()`, e.g. when using `formfield_overrides`.

Django 1.11.20 release notes

February 11, 2019

Django 1.11.20 fixes a packaging error in 1.11.19.

Bugfixes

- Corrected packaging error from 1.11.19 (#30175).

Django 1.11.19 release notes

February 11, 2019

Django 1.11.19 fixes a security issue in 1.11.18.

CVE-2019-6975: Memory exhaustion in `django.utils.numberformat.format()`

If `django.utils.numberformat.format()` –used by `contrib.admin` as well as the `floatformat`, `filesizeformat`, and `intcomma` templates filters –received a `Decimal` with a large number of digits or a large exponent, it could lead to significant memory usage due to a call to `'{:f}'.format()`.

To avoid this, decimals with more than 200 digits are now formatted using scientific notation.

Django 1.11.18 release notes

January 4, 2019

Django 1.11.18 fixes a security issue in 1.11.17.

CVE-2019-3498: Content spoofing possibility in the default 404 page

An attacker could craft a malicious URL that could make spoofed content appear on the default page generated by the `django.views.defaults.page_not_found()` view.

The URL path is no longer displayed in the default 404 template and the `request_path` context variable is now quoted to fix the issue for custom templates that use the path.

Django 1.11.17 release notes

December 3, 2018

Django 1.11.17 fixes several bugs in 1.11.16 and adds compatibility with Python 3.7.

Bugfixes

- Prevented repetitive calls to `geos_version_tuple()` in the `WKBWriter` class in an attempt to fix a random crash involving `LooseVersion` since Django 1.11.14 ([#29959](#)).

Django 1.11.16 release notes

October 1, 2018

Django 1.11.16 fixes a data loss bug in 1.11.15.

Bugfixes

- Fixed a race condition in `QuerySet.update_or_create()` that could result in data loss ([#29499](#)).

Django 1.11.15 release notes

August 1, 2018

Django 1.11.15 fixes a security issue in 1.11.14.

CVE-2018-14574: Open redirect possibility in `CommonMiddleware`

If the `CommonMiddleware` and the `APPEND_SLASH` setting are both enabled, and if the project has a URL pattern that accepts any path ending in a slash (many content management systems have such a pattern), then a request to a maliciously crafted URL of that site could lead to a redirect to another site, enabling phishing and other attacks.

`CommonMiddleware` now escapes leading slashes to prevent redirects to other domains.

Django 1.11.14 release notes

July 2, 2018

Django 1.11.14 fixes several bugs in 1.11.13.

Bugfixes

- Fixed `WKBWriter.write()` and `write_hex()` for empty polygons on GEOS 3.6.1+ ([#29460](#)).
- Fixed a regression in Django 1.10 that could result in large memory usage when making edits using `ModelAdmin.list_editable` ([#28462](#)).

Django 1.11.13 release notes

May 1, 2018

Django 1.11.13 fixes several bugs in 1.11.12.

Bugfixes

- Fixed a regression in Django 1.11.8 where altering a field with a unique constraint may drop and rebuild more foreign keys than necessary ([#29193](#)).
- Fixed crashes in `django.contrib.admindocs` when a view is a callable object, such as `django.contrib.syndication.views.Feed` ([#29296](#)).
- Fixed a regression in Django 1.11.12 where `QuerySet.values()` or `values_list()` after combining an annotated and unannotated queryset with `union()`, `difference()`, or `intersection()` crashed due to mismatching columns ([#29286](#)).

Django 1.11.12 release notes

April 2, 2018

Django 1.11.12 fixes two bugs in 1.11.11.

Bugfixes

- Fixed a regression in Django 1.11.8 where combining two annotated `values_list()` querysets with `union()`, `difference()`, or `intersection()` crashed due to mismatching columns ([#29229](#)).
- Fixed a regression in Django 1.11 where an empty choice could be initially selected for the `SelectMultiple` and `CheckboxSelectMultiple` widgets ([#29273](#)).

Django 1.11.11 release notes

March 6, 2018

Django 1.11.11 fixes two security issues in 1.11.10.

CVE-2018-7536: Denial-of-service possibility in `urlize` and `urlizetrunc` template filters

The `django.utils.html.urlize()` function was extremely slow to evaluate certain inputs due to catastrophic backtracking vulnerabilities in two regular expressions. The `urlize()` function is used to implement the `urlize` and `urlizetrunc` template filters, which were thus vulnerable.

The problematic regular expressions are replaced with parsing logic that behaves similarly.

CVE-2018-7537: Denial-of-service possibility in `truncatechars_html` and `truncatewords_html` template filters

If `django.utils.text.Truncator`'s `chars()` and `words()` methods were passed the `html=True` argument, they were extremely slow to evaluate certain inputs due to a catastrophic backtracking vulnerability in a regular expression. The `chars()` and `words()` methods are used to implement the `truncatechars_html` and `truncatewords_html` template filters, which were thus vulnerable.

The backtracking problem in the regular expression is fixed.

Django 1.11.10 release notes

February 1, 2018

Django 1.11.10 fixes a security issue and several bugs in 1.11.9.

CVE-2018-6188: Information leakage in `AuthenticationForm`

A regression in Django 1.11.8 made `AuthenticationForm` run its `confirm_login_allowed()` method even if an incorrect password is entered. This can leak information about a user, depending on what messages `confirm_login_allowed()` raises. If `confirm_login_allowed()` isn't overridden, an attacker enter an arbitrary username and see if that user has been set to `is_active=False`. If `confirm_login_allowed()` is overridden, more sensitive details could be leaked.

This issue is fixed with the caveat that `AuthenticationForm` can no longer raise the “This account is inactive.” error if the authentication backend rejects inactive users (the default authentication backend, `ModelBackend`, has done that since Django 1.10). This issue will be revisited for Django 2.1 as a fix to address the caveat will likely be too invasive for inclusion in older versions.

Bugfixes

- Fixed incorrect foreign key nullification if a model has two foreign keys to the same model and a target model is deleted (#29016).
- Fixed a regression where `contrib.auth.authenticate()` crashes if an authentication backend doesn't accept `request` and a later one does (#29071).
- Fixed crash when entering an invalid uuid in `ModelAdmin.raw_id_fields` (#29094).

Django 1.11.9 release notes

January 1, 2018

Django 1.11.9 fixes several bugs in 1.11.8.

Bugfixes

- Fixed a regression in Django 1.11 that added newlines between `MultiWidget`'s subwidgets (#28890).
- Fixed incorrect class-based model index name generation for models with quoted `db_table` (#28876).
- Fixed incorrect foreign key constraint name for models with quoted `db_table` (#28876).
- Fixed a regression in caching of a `GenericForeignKey` when the referenced model instance uses more than one level of multi-table inheritance (#28856).

Django 1.11.8 release notes

December 2, 2017

Django 1.11.8 fixes several bugs in 1.11.7.

Bugfixes

- Reallowed, following a regression in Django 1.10, `AuthenticationForm` to raise the inactive user error when using `ModelBackend` (#28645).
- Added support for `QuerySet.values()` and `values_list()` for `union()`, `difference()`, and `intersection()` queries (#28781).
- Fixed incorrect index name truncation when using a namespaced `db_table` (#28792).
- Made `QuerySet.iterator()` use server-side cursors on PostgreSQL after `values()` and `values_list()` (#28817).

- Fixed crash on SQLite and MySQL when ordering by a filtered subquery that uses `nulls_first` or `nulls_last` (#28848).
- Made query lookups for `CCharField`, `CIntegerField`, and `CTextField` use a `citext` cast (#28702).
- Fixed a regression in caching of a `GenericForeignKey` when the referenced model instance uses multi-table inheritance (#28856).
- Fixed “Cannot change column ‘x’ : used in a foreign key constraint” crash on MySQL with a sequence of `AlterField` and/or `RenameField` operations in a migration (#28305).

Django 1.11.7 release notes

November 1, 2017

Django 1.11.7 fixes several bugs in 1.11.6.

Bugfixes

- Prevented `cache.get_or_set()` from caching `None` if the default argument is a callable that returns `None` (#28601).
- Fixed the Basque `DATE_FORMAT` string (#28710).
- Made `QuerySet.reverse()` affect `nulls_first` and `nulls_last` (#28722).
- Fixed unquoted table names in Subquery SQL when using `OuterRef` (#28689).

Django 1.11.6 release notes

October 5, 2017

Django 1.11.6 fixes several bugs in 1.11.5.

Bugfixes

- Made the `CharField` form field convert whitespace-only values to the `empty_value` when `strip` is enabled (#28555).
- Fixed crash when using the name of a model’s autogenerated primary key (`id`) in an `Index`’s fields (#28597).
- Fixed a regression in Django 1.9 where a custom view error handler such as `handler404` that accesses `csrf_token` could cause CSRF verification failures on other pages (#28488).

Django 1.11.5 release notes

September 5, 2017

Django 1.11.5 fixes a security issue and several bugs in 1.11.4.

CVE-2017-12794: Possible XSS in traceback section of technical 500 debug page

In older versions, HTML autoescaping was disabled in a portion of the template for the technical 500 debug page. Given the right circumstances, this allowed a cross-site scripting attack. This vulnerability shouldn't affect most production sites since you shouldn't run with `DEBUG = True` (which makes this page accessible) in your production settings.

Bugfixes

- Fixed GEOS version parsing if the version has a commit hash at the end (new in GEOS 3.6.2) ([#28441](#)).
- Added compatibility for `cx_Oracle` 6 ([#28498](#)).
- Fixed select widget rendering when option values are tuples ([#28502](#)).
- Django 1.11 inadvertently changed the sequence and trigger naming scheme on Oracle. This causes errors on INSERTs for some tables if `'use_returning_into': False` is in the `OPTIONS` part of `DATABASES`. The pre-1.11 naming scheme is now restored. Unfortunately, it necessarily requires an update to Oracle tables created with Django 1.11.[1-4]. Use the upgrade script in [#28451](#) comment 8 to update sequence and trigger names to use the pre-1.11 naming scheme.
- Added POST request support to `LogoutView`, for equivalence with the function-based `logout()` view ([#28513](#)).
- Omitted `pages_per_range` from `BrinIndex.deconstruct()` if it's `None` ([#25809](#)).
- Fixed a regression where `SelectDateWidget` localized the years in the select box ([#28530](#)).
- Fixed a regression in 1.11.4 where `runserver` crashed with non-Unicode system encodings on Python 2 + Windows ([#28487](#)).
- Fixed a regression in Django 1.10 where changes to a `ManyToManyField` weren't logged in the admin change history ([#27998](#)) and prevented `ManyToManyField` initial data in model forms from being affected by subsequent model changes ([#28543](#)).
- Fixed non-deterministic results or an `AssertionError` crash in some queries with multiple joins ([#26522](#)).
- Fixed a regression in `contrib.auth`'s `login()` and `logout()` views where they ignored positional arguments ([#28550](#)).

Django 1.11.4 release notes

August 1, 2017

Django 1.11.4 fixes several bugs in 1.11.3.

Bugfixes

- Fixed a regression in 1.11.3 on Python 2 where non-ASCII `format` values for date/time widgets results in an empty value in the widget's HTML ([#28355](#)).
- Fixed `QuerySet.union()` and `difference()` when combining with a queryset raising `EmptyResultSet` ([#28378](#)).
- Fixed a regression in pickling of `LazyObject` on Python 2 when the wrapped object doesn't have `__reduce__()` ([#28389](#)).
- Fixed crash in `runserver`'s autoreload with Python 2 on Windows with non-`str` environment variables ([#28174](#)).
- Corrected `Field.has_changed()` to return `False` for disabled form fields: `BooleanField`, `MultipleChoiceField`, `MultiValueField`, `FileField`, `ModelChoiceField`, and `ModelMultipleChoiceField`.
- Fixed `QuerySet.count()` for `union()`, `difference()`, and `intersection()` queries. ([#28399](#)).
- Fixed `ClearableFileInput` rendering as a subwidget of `MultiWidget` ([#28414](#)). Custom `clearable_file_input.html` widget templates will need to adapt for the fact that context values `checkbox_name`, `checkbox_id`, `is_initial`, `input_text`, `initial_text`, and `clear_checkbox_label` are now attributes of `widget` rather than appearing in the top-level context.
- Fixed queryset crash when using a `GenericRelation` to a proxy model ([#28418](#)).

Django 1.11.3 release notes

July 1, 2017

Django 1.11.3 fixes several bugs in 1.11.2.

Bugfixes

- Removed an incorrect deprecation warning about a missing `renderer` argument if a `Widget.render()` method accepts `**kwargs` (#28265).
- Fixed a regression causing `Model.__init__()` to crash if a field has an instance only descriptor (#28269).
- Fixed an incorrect `DisallowedModelAdminLookup` exception when using a nested reverse relation in `list_filter` (#28262).
- Fixed admin's `FieldListFilter.get_queryset()` crash on invalid input (#28202).
- Fixed invalid HTML for a required `AdminFileWidget` (#28278).
- Fixed model initialization to set the name of class-based model indexes for models that only inherit `models.Model` (#28282).
- Fixed crash in admin's inlines when a model has an inherited non-editable primary key (#27967).
- Fixed `QuerySet.union()`, `intersection()`, and `difference()` when combining with an `EmptyQuerySet` (#28293).
- Prevented `Paginator`'s unordered object list warning from evaluating a `QuerySet` (#28284).
- Fixed the value of `redirect_field_name` in `LoginView`'s template context. It's now an empty string (as it is for the original function-based `login()` view) if the corresponding parameter isn't sent in a request (in particular, when the login page is accessed directly) (#28229).
- Prevented attribute values in the `django/forms/widgets/attrs.html` template from being localized so that numeric attributes (e.g. `max` and `min`) of `NumberInput` work correctly (#28303).
- Removed casting of the option value to a string in the template context of the `CheckboxSelectMultiple`, `NullBooleanSelect`, `RadioSelect`, `SelectMultiple`, and `Select` widgets (#28176). In Django 1.11.1, casting was added in Python to avoid localization of numeric values in Django templates, but this made some use cases more difficult. Casting is now done in the template using the `|stringformat:'s'` filter.
- Prevented a primary key alteration from adding a foreign key constraint if `db_constraint=False` (#28298).
- Fixed `UnboundLocalError` crash in `RenameField` with nonexistent field (#28350).
- Fixed a regression preventing a model field's `limit_choices_to` from being evaluated when a `ModelForm` is instantiated (#28345).

Django 1.11.2 release notes

June 1, 2017

Django 1.11.2 adds a minor feature and fixes several bugs in 1.11.1. Also, the latest string translations from Transifex are incorporated.

Minor feature

The new `LiveServerTestCase.port` attribute realloes the use case of binding to a specific port following the [bind to port zero](#) change in Django 1.11.

Bugfixes

- Added detection for GDAL 2.1 and 2.0, and removed detection for unsupported versions 1.7 and 1.8 ([#28181](#)).
- Changed `contrib.gis` to raise `ImproperlyConfigured` rather than `GDALException` if `gdal` isn't installed, to allow third-party apps to catch that exception ([#28178](#)).
- Fixed `django.utils.http.is_safe_url()` crash on invalid IPv6 URLs ([#28142](#)).
- Fixed regression causing pickling of model fields to crash ([#28188](#)).
- Fixed `django.contrib.auth.authenticate()` when multiple authentication backends don't accept a positional `request` argument ([#28207](#)).
- Fixed introspection of index field ordering on PostgreSQL ([#28197](#)).
- Fixed a regression where `Model._state.adding` wasn't set correctly on multi-table inheritance parent models after saving a child model ([#28210](#)).
- Allowed `Django.JSONEncoder` to serialize `django.utils.deprecation.CallableBool` ([#28230](#)).
- Relaxed the validation added in Django 1.11 of the fields in the `defaults` argument of `QuerySet.get_or_create()` and `update_or_create()` to reallo settable model properties ([#28222](#)).
- Fixed `MultipleObjectMixin.paginate_queryset()` crash on Python 2 if the `InvalidPage` message contains non-ASCII ([#28204](#)).
- Prevented `Subquery` from adding an unnecessary `CAST` which resulted in invalid SQL ([#28199](#)).
- Corrected detection of GDAL 2.1 on Windows ([#28181](#)).
- Made date-based generic views return a 404 rather than crash when given an out of range date ([#28209](#)).
- Fixed a regression where `file_move_safe()` crashed when moving files to a CIFS mount ([#28170](#)).
- Moved the `ImageField` file extension validation added in Django 1.11 from the model field to the form field to reallo the use case of storing images without an extension ([#28242](#)).

Django 1.11.1 release notes

May 6, 2017

Django 1.11.1 adds a minor feature and fixes several bugs in 1.11.

Allowed disabling server-side cursors on PostgreSQL

The change in Django 1.11 to make `QuerySet.iterator()` use server-side cursors on PostgreSQL prevents running Django with PgBouncer in transaction pooling mode. To reallow that, use the `DISABLE_SERVER_SIDE_CURSORS` setting in `DATABASES`.

See [Transaction pooling and server-side cursors](#) for more discussion.

Bugfixes

- Made migrations respect `Index`'s `name` argument. If you created a named index with Django 1.11, `makemigrations` will create a migration to recreate the index with the correct name (#28051).
- Fixed a crash when using a `__icontains` lookup on a `ArrayField` (#28038).
- Fixed a crash when using a two-tuple in `EmailMessage`'s `attachments` argument (#28042).
- Fixed `QuerySet.filter()` crash when it references the name of a `OneToOneField` primary key (#28047).
- Fixed empty POST data table appearing instead of “No POST data” in HTML debug page (#28079).
- Restored `BoundFields` without any `choices` evaluating to `True` (#28058).
- Prevented `SessionBase.cycle_key()` from losing session data if `_session_cache` isn't populated (#28066).
- Fixed layout of `ReadOnlyPasswordHashWidget` (used in the admin's user change page) (#28097).
- Allowed prefetch calls on managers with custom `ModelIterable` subclasses (#28096).
- Fixed change password link in the `contrib.auth` admin for `el`, `es_MX`, and `pt` translations (#28100).
- Restored the output of the `class` attribute in the `<ul>` of widgets that use the `multiple_input.html` template. This fixes `ModelAdmin.radio_fields` with `admin.HORIZONTAL` (#28059).
- Fixed crash in `BaseGeometryWidget.subwidgets()` (#28039).
- Fixed exception reraising in ORM query execution when `cursor.execute()` fails and the subsequent `cursor.close()` also fails (#28091).
- Fixed a regression where `CheckboxSelectMultiple`, `NullBooleanSelect`, `RadioSelect`, `SelectMultiple`, and `Select` localized option values (#28075).
- Corrected the stack level of unordered queryset pagination warnings (#28109).

- Fixed a regression causing incorrect queries for `__in` subquery lookups when models use `ForeignKey.to_field` (#28101).
- Fixed crash when overriding the template of `django.views.static.directory_index()` (#28122).
- Fixed a regression in formset `min_num` validation with unchanged forms that have initial data (#28130).
- Prepared for `cx_Oracle` 6.0 support (#28138).
- Updated the `contrib.postgres.SplitArrayWidget` to use template-based widget rendering (#28040).
- Fixed crash in `BaseGeometryWidget.get_context()` when overriding existing `attrs` (#28105).
- Prevented `AddIndex` and `RemoveIndex` from mutating model state (#28043).
- Prevented migrations from dropping database indexes from `Meta.indexes` when changing `Field.db_index` to `False` (#28052).
- Fixed a regression in choice ordering in form fields with grouped and non-grouped options (#28157).
- Fixed crash in `BaseInlineFormSet._construct_form()` when using `save_as_new` (#28159).
- Fixed a regression where `Model._state.db` wasn't set correctly on multi-table inheritance parent models after saving a child model (#28166).
- Corrected the return type of `ArrayField(CITextField())` values retrieved from the database (#28161).
- Fixed `QuerySet.prefetch_related()` crash when fetching relations in nested `Prefetch` objects (#27554).
- Prevented hiding GDAL errors if it's not installed when using `contrib.gis` (#28160). (It's a required dependency as of Django 1.11.)
- Fixed a regression causing `__in` lookups on a foreign key to fail when using the foreign key's parent model as the lookup value (#28175).

Django 1.11 release notes

April 4, 2017

Welcome to Django 1.11!

These release notes cover the [new features](#), as well as some [backwards incompatible changes](#) you'll want to be aware of when upgrading from Django 1.10 or older versions. We've begun the deprecation process for [some features](#).

See the [How to upgrade Django to a newer version](#) guide if you're updating an existing project.

Django 1.11 is designated as a [long-term support release](#). It will receive security updates for at least three years after its release. Support for the previous LTS, Django 1.8, will end in April 2018.

Python compatibility

Django 1.11 requires Python 2.7, 3.4, 3.5, 3.6, or 3.7 (as of 1.11.17). We highly recommend and only officially support the latest release of each series.

The Django 1.11.x series is the last to support Python 2. The next major release, Django 2.0, will only support Python 3.4+.

Deprecating warnings are no longer loud by default

Unlike older versions of Django, Django's own deprecation warnings are no longer displayed by default. This is consistent with Python's default behavior.

This change allows third-party apps to support both Django 1.11 LTS and Django 1.8 LTS without having to add code to avoid deprecation warnings.

Following the release of Django 2.0, we suggest that third-party app authors drop support for all versions of Django prior to 1.11. At that time, you should be able run your package's tests using `python -Wd` so that deprecation warnings do appear. After making the deprecation warning fixes, your app should be compatible with Django 2.0.

What's new in Django 1.11

Class-based model indexes

The new `django.db.models.indexes` module contains classes which ease creating database indexes. Indexes are added to models using the `Meta.indexes` option.

The `Index` class creates a b-tree index, as if you used `db_index` on the model field or `index_together` on the model `Meta` class. It can be subclassed to support different index types, such as `GinIndex`. It also allows defining the order (ASC/DESC) for the columns of the index.

Template-based widget rendering

To ease customizing widgets, form widget rendering is now done using the template system rather than in Python. See [The form rendering API](#).

You may need to adjust any custom widgets that you've written for a few [backwards incompatible changes](#).

Subquery expressions

The new *Subquery* and *Exists* database expressions allow creating explicit subqueries. Subqueries may refer to fields from the outer queryset using the *OuterRef* class.

Minor features

`django.contrib.admin`

- *ModelAdmin.date_hierarchy* can now reference fields across relations.
- The new *ModelAdmin.get_exclude()* hook allows specifying the exclude fields based on the request or model instance.
- The `popup_response.html` template can now be overridden per app, per model, or by setting the *ModelAdmin.popup_response_template* attribute.

`django.contrib.auth`

- The default iteration count for the PBKDF2 password hasher is increased by 20%.
- The *LoginView* and *LogoutView* class-based views supersede the deprecated `login()` and `logout()` function-based views.
- The *PasswordChangeView*, *PasswordChangeDoneView*, *PasswordResetView*, *PasswordResetDoneView*, *PasswordResetConfirmView*, and *PasswordResetCompleteView* class-based views supersede the deprecated `password_change()`, `password_change_done()`, `password_reset()`, `password_reset_done()`, `password_reset_confirm()`, and `password_reset_complete()` function-based views.
- The new `post_reset_login` attribute for *PasswordResetConfirmView* allows automatically logging in a user after a successful password reset. If you have multiple `AUTHENTICATION_BACKENDS` configured, use the `post_reset_login_backend` attribute to choose which one to use.
- To avoid the possibility of leaking a password reset token via the HTTP Referer header (for example, if the reset page includes a reference to CSS or JavaScript hosted on another domain), the *PasswordResetConfirmView* (but not the deprecated `password_reset_confirm()` function-based view) stores the token in a session and redirects to itself to present the password change form to the user without the token in the URL.
- *update_session_auth_hash()* now rotates the session key to allow a password change to invalidate stolen session cookies.
- The new `success_url_allowed_hosts` attribute for *LoginView* and *LogoutView* allows specifying a set of hosts that are safe for redirecting after login and logout.

- Added password validators `help_text` to *UserCreationForm*.
- The `HttpRequest` is now passed to *authenticate()* which in turn passes it to the authentication backend if it accepts a `request` argument.
- The *user_login_failed()* signal now receives a `request` argument.
- *PasswordResetForm* supports custom user models that use an email field named something other than `'email'`. Set *CustomUser.EMAIL_FIELD* to the name of the field.
- *get_user_model()* can now be called at import time, even in modules that define models.

`django.contrib.contenttypes`

- When stale content types are detected in the *remove_stale_contenttypes* command, there's now a list of related objects such as `auth.Permissions` that will also be deleted. Previously, only the content types were listed (and this prompt was after `migrate` rather than in a separate command).

`django.contrib.gis`

- The new *GEOSGeometry.from_gml()* and *OGRGeometry.from_gml()* methods allow creating geometries from GML.
- Added support for the *dwithin* lookup on Spatialite.
- The *Area* function, *Distance* function, and distance lookups now work with geodetic coordinates on Spatialite.
- The OpenLayers-based form widgets now use `OpenLayers.js` from `https://cdnjs.cloudflare.com` which is more suitable for production use than the old `https://openlayers.org/` source. They are also updated to use OpenLayers 3.
- PostGIS migrations can now change field dimensions.
- Added the ability to pass the `size`, `shape`, and `offset` parameters when creating *GDALRaster* objects.
- Added Spatialite support for the *IsValid* function, *MakeValid* function, and *isvalid* lookup.
- Added Oracle support for the *AsGML* function, *BoundingBox* function, *IsValid* function, and *isvalid* lookup.

`django.contrib.postgres`

- The new `distinct` argument for *StringAgg* determines if concatenated values will be distinct.
- The new *GinIndex* and *BrinIndex* classes allow creating GIN and BRIN indexes in the database.
- `django.contrib.postgres.fields.JSONField` accepts a new `encoder` parameter to specify a custom class to encode data types not supported by the standard encoder.
- The new `CIText` mixin and *CITextExtension* migration operation allow using PostgreSQL's `citext` extension for case-insensitive lookups. Three fields are provided: `CCharField`, `CEmailField`, and `CITextField`.
- The new *JSONBAgg* allows aggregating values as a JSON array.
- The *HStoreField* (model field) and *HStoreField* (form field) allow storing null values.

Cache

- Memcached backends now pass the contents of *OPTIONS* as keyword arguments to the client constructors, allowing for more advanced control of client behavior. See the [cache arguments](#) documentation for examples.
- Memcached backends now allow defining multiple servers as a comma-delimited string in *LOCATION*, for convenience with third-party services that use such strings in environment variables.

CSRF

- Added the *CSRF_USE_SESSIONS* setting to allow storing the CSRF token in the user's session rather than in a cookie.

Database backends

- Added the `skip_locked` argument to *QuerySet.select_for_update()* on PostgreSQL 9.5+ and Oracle to execute queries with `FOR UPDATE SKIP LOCKED`.
- Added the *TEST['TEMPLATE']* setting to let PostgreSQL users specify a template for creating the test database.
- *QuerySet.iterator()* now uses [server-side cursors](#) on PostgreSQL. This feature transfers some of the worker memory load (used to hold query results) to the database and might increase database memory usage.
- Added MySQL support for the `'isolation_level'` option in *OPTIONS* to allow specifying the [transaction isolation level](#). To avoid possible data loss, it's recommended to switch from MySQL's default level, `repeatable read`, to `read committed`.

- Added support for `cx_Oracle` 5.3.

Email

- Added the `EMAIL_USE_LOCALTIME` setting to allow sending SMTP date headers in the local time zone rather than in UTC.
- `EmailMessage.attach()` and `attach_file()` now fall back to MIME type `application/octet-stream` when binary content that can't be decoded as UTF-8 is specified for a `text/*` attachment.

File Storage

- To make it wrappable by `io.TextIOWrapper`, `File` now has the `readable()`, `writable()`, and `seekable()` methods.

Forms

- The new `empty_value` attribute on `CharField`, `EmailField`, `RegexField`, `SlugField`, and `URLField` allows specifying the Python value to use to represent “empty” .
- The new `Form.get_initial_for_field()` method returns initial data for a form field.

Internationalization

- Number formatting and the `NUMBER_GROUPING` setting support non-uniform digit grouping.

Management Commands

- The new `loaddata --exclude` option allows excluding models and apps while loading data from fixtures.
- The new `diffsettings --default` option allows specifying a settings module other than Django's default settings to compare against.
- `app_labels` arguments now limit the `showmigrations --plan` output.

Migrations

- Added support for serialization of `uuid.UUID` objects.

Models

- Added support for callable values in the `defaults` argument of `QuerySet.update_or_create()` and `get_or_create()`.
- `ImageField` now has a default `validate_image_file_extension` validator. (This validator moved to the form field in Django 1.11.2.)
- Added support for time truncation to `Trunc` functions.
- Added the `ExtractWeek` function to extract the week from `DateField` and `DateTimeField` and exposed it through the `week` lookup.
- Added the `TruncTime` function to truncate `DateTimeField` to its time component and exposed it through the `time` lookup.
- Added support for expressions in `QuerySet.values()` and `values_list()`.
- Added support for query expressions on lookups that take multiple arguments, such as `range`.
- You can now use the `unique=True` option with `FileField`.
- Added the `nulls_first` and `nulls_last` parameters to `Expression.asc()` and `desc()` to control the ordering of null values.
- The new F expression `bitleftshift()` and `bitrightshift()` methods allow bitwise shift operations.
- Added `QuerySet.union()`, `intersection()`, and `difference()`.

Requests and Responses

- Added `QueryDict.fromkeys()`.
- `CommonMiddleware` now sets the `Content-Length` response header for non-streaming responses.
- Added the `SECURE_HSTS_PRELOAD` setting to allow appending the `preload` directive to the `Strict-Transport-Security` header.
- `ConditionalGetMiddleware` now adds the `ETag` header to responses.

Serialization

- The new `django.core.serializers.base.Serializer.stream_class` attribute allows subclasses to customize the default stream.
- The encoder used by the `JSON serializer` can now be customized by passing a `cls` keyword argument to the `serializers.serialize()` function.
- `DjangoJSONEncoder` now serializes `timedelta` objects (used by `DurationField`).

Templates

- `mark_safe()` can now be used as a decorator.
- The `Jinja2` template backend now supports context processors by setting the `'context_processors'` option in `OPTIONS`.
- The `regroup` tag now returns `namedtuples` instead of dictionaries so you can unpack the group object directly in a loop, e.g. `{% for grouper, list in regrouped %}`.
- Added a `resetcycle` template tag to allow resetting the sequence of the `cycle` template tag.
- You can now specify specific directories for a particular `filesystem.Loader`.

Tests

- Added `DiscoverRunner.get_test_runner_kwargs()` to allow customizing the keyword arguments passed to the test runner.
- Added the `test --debug-mode` option to help troubleshoot test failures by setting the `DEBUG` setting to `True`.
- The new `django.test.utils.setup_databases()` (moved from `django.test.runner`) and `teardown_databases()` functions make it easier to build custom test runners.
- Added support for `unittest.TestCase.subTest()`'s when using the `test --parallel` option.
- `DiscoverRunner` now runs the system checks at the start of a test run. Override the `DiscoverRunner.run_checks()` method if you want to disable that.

Validators

- Added *FileExtensionValidator* to validate file extensions and *validate_image_file_extension* to validate image files.

Backwards incompatible changes in 1.11

`django.contrib.gis`

- To simplify the codebase and because it's easier to install than when `contrib.gis` was first released, *GDAL* is now a required dependency for GeoDjango. In older versions, it's only required for SQLite.
- `contrib.gis.maps` is removed as it interfaces with a retired version of the Google Maps API and seems to be unmaintained. If you're using it, [let us know](#).
- The *GEOSGeometry* equality operator now also compares SRID.
- The OpenLayers-based form widgets now use OpenLayers 3, and the `gis/openlayers.html` and `gis/openlayers-osm.html` templates have been updated. Check your project if you subclass these widgets or extend the templates. Also, the new widgets work a bit differently than the old ones. Instead of using a toolbar in the widget, you click to draw, click and drag to move the map, and click and drag a point/vertex/corner to move it.
- Support for SpatiaLite < 4.0 is dropped.
- Support for GDAL 1.7 and 1.8 is dropped.
- The widgets in `contrib.gis.forms.widgets` and the admin's `OpenLayersWidget` use the [form rendering API](#) rather than `loader.render_to_string()`. If you're using a custom widget template, you'll need to be sure your form renderer can locate it. For example, you could use the *TemplatesSetting* renderer.

`django.contrib.staticfiles`

- `collectstatic` may now fail during post-processing when using a hashed static files storage if a reference loop exists (e.g. `'foo.css'` references `'bar.css'` which itself references `'foo.css'`) or if the chain of files referencing other files is too deep to resolve in several passes. In the latter case, increase the number of passes using *ManifestStaticFilesStorage.max_post_process_passes*.
- When using *ManifestStaticFilesStorage*, static files not found in the manifest at runtime now raise a *ValueError* instead of returning an unchanged path. You can revert to the old behavior by setting *ManifestStaticFilesStorage.manifest_strict* to `False`.

Database backend API

This section describes changes that may be needed in third-party database backends.

- The `DatabaseOperations.time_trunc_sql()` method is added to support `TimeField` truncation. It accepts a `lookup_type` and `field_name` arguments and returns the appropriate SQL to truncate the given time field `field_name` to a time object with only the given specificity. The `lookup_type` argument can be either `'hour'`, `'minute'`, or `'second'`.
- The `DatabaseOperations.datetime_cast_time_sql()` method is added to support the `time` lookup. It accepts a `field_name` and `tzname` arguments and returns the SQL necessary to cast a datetime value to time value.
- To enable `FOR UPDATE SKIP LOCKED` support, set `DatabaseFeatures.has_select_for_update_skip_locked = True`.
- The new `DatabaseFeatures.supports_index_column_ordering` attribute specifies if a database allows defining ordering for columns in indexes. The default value is `True` and the `DatabaseIntrospection.get_constraints()` method should include an `'orders'` key in each of the returned dictionaries with a list of `'ASC'` and/or `'DESC'` values corresponding to the ordering of each column in the index.
- `inspectdb` no longer calls `DatabaseIntrospection.get_indexes()` which is deprecated. Custom database backends should ensure all types of indexes are returned by `DatabaseIntrospection.get_constraints()`.
- Renamed the `ignores_quoted_identifier_case` feature to `ignores_table_name_case` to more accurately reflect how it is used.
- The `name` keyword argument is added to the `DatabaseWrapper.create_cursor(self, name=None)` method to allow usage of server-side cursors on backends that support it.

Dropped support for PostgreSQL 9.2 and PostGIS 2.0

Upstream support for PostgreSQL 9.2 ends in September 2017. As a consequence, Django 1.11 sets PostgreSQL 9.3 as the minimum version it officially supports.

Support for PostGIS 2.0 is also removed as PostgreSQL 9.2 is the last version to support it.

Also, the minimum supported version of `psycopg2` is increased from 2.4.5 to 2.5.4.

LiveServerTestCase binds to port zero

Rather than taking a port range and iterating to find a free port, `LiveServerTestCase` binds to port zero and relies on the operating system to assign a free port. The `DJANGO_LIVE_TEST_SERVER_ADDRESS` environment variable is no longer used, and as it's also no longer used, the `manage.py test --liveserver` option is removed.

If you need to bind `LiveServerTestCase` to a specific port, use the `port` attribute added in Django 1.11.2.

Protection against insecure redirects in `django.contrib.auth` and `18n` views

`LoginView`, `LogoutView` (and the deprecated function-based equivalents), and `set_language()` protect users from being redirected to non-HTTPS next URLs when the app is running over HTTPS.

`QuerySet.get_or_create()` and `update_or_create()` validate arguments

To prevent typos from passing silently, `get_or_create()` and `update_or_create()` check that their arguments are model fields. This should be backwards-incompatible only in the fact that it might expose a bug in your project.

pytz is a required dependency and support for `settings.TIME_ZONE = None` is removed

To simplify Django's timezone handling, `pytz` is now a required dependency. It's automatically installed along with Django.

Support for `settings.TIME_ZONE = None` is removed as the behavior isn't commonly used and is questionably useful. If you want to automatically detect the timezone based on the system timezone, you can use `tzlocal`:

```
from tzlocal import get_localzone

TIME_ZONE = get_localzone().zone
```

This works similar to `settings.TIME_ZONE = None` except that it also sets `os.environ['TZ']`. [Let us know](#) if there's a use case where you find you can't adapt your code to set a `TIME_ZONE`.

HTML changes in admin templates

`<p class="help">` is replaced with a `<div>` tag to allow including lists inside help text.

Read-only fields are wrapped in `<div class="readonly">...</div>` instead of `<p>...</p>` to allow any kind of HTML as the field's content.

Changes due to the introduction of template-based widget rendering

Some undocumented classes in `django.forms.widgets` are removed:

- `SubWidget`
- `RendererMixin`, `ChoiceFieldRenderer`, `RadioFieldRenderer`, `CheckboxFieldRenderer`
- `ChoiceInput`, `RadioChoiceInput`, `CheckboxChoiceInput`

The undocumented `Select.render_option()` method is removed.

The `Widget.format_output()` method is removed. Use a custom widget template instead.

Some widget values, such as `<select>` options, are now localized if `settings.USE_L10N=True`. You could revert to the old behavior with custom widget templates that uses the *localize* template tag to turn off localization.

`django.template.backends.django.Template.render()` prohibits non-dict context

For compatibility with multiple template engines, `django.template.backends.django.Template.render()` (returned from high-level template loader APIs such as `loader.get_template()`) must receive a dictionary of context rather than `Context` or `RequestContext`. If you were passing either of the two classes, pass a dictionary instead –doing so is backwards-compatible with older versions of Django.

Model state changes in migration operations

To improve the speed of applying migrations, rendering of related models is delayed until an operation that needs them (e.g. `RunPython`). If you have a custom operation that works with model classes or model instances from the `from_state` argument in `database_forwards()` or `database_backwards()`, you must render model states using the `clear_delayed_apps_cache()` method as described in [writing your own migration operation](#).

Server-side cursors on PostgreSQL

The change to make `QuerySet.iterator()` use server-side cursors on PostgreSQL prevents running Django with PgBouncer in transaction pooling mode. To reallow that, use the `DISABLE_SERVER_SIDE_CURSORS` setting (added in Django 1.11.1) in `DATABASES`.

See [Transaction pooling and server-side cursors](#) for more discussion.

Miscellaneous

- If no items in the feed have a `pubdate` or `updateddate` attribute, `SyndicationFeed.latest_post_date()` now returns the current UTC date/time, instead of a datetime without any timezone information.
- CSRF failures are logged to the `django.security.csrf` logger instead of `django.request`.
- `ALLOWED_HOSTS` validation is no longer disabled when running tests. If your application includes tests with custom host names, you must include those host names in `ALLOWED_HOSTS`. See [Tests and multiple host names](#).
- Using a foreign key's id (e.g. `'field_id'`) in `ModelAdmin.list_display` displays the related object's ID. Remove the `_id` suffix if you want the old behavior of the string representation of the object.
- In model forms, `CharField` with `null=True` now saves NULL for blank values instead of empty strings.
- On Oracle, `Model.validate_unique()` no longer checks empty strings for uniqueness as the database interprets the value as NULL.
- If you subclass `AbstractUser` and override `clean()`, be sure it calls `super()`. `BaseUserManager.normalize_email()` is called in a new `AbstractUser.clean()` method so that normalization is applied in cases like model form validation.
- `EmailField` and `URLField` no longer accept the `strip` keyword argument. Remove it because it doesn't have an effect in older versions of Django as these fields always strip whitespace.
- The `checked` and `selected` attribute rendered by form widgets now uses HTML5 boolean syntax rather than XHTML's `checked='checked'` and `selected='selected'`.
- `RelatedManager.add()`, `remove()`, `clear()`, and `set()` now clear the `prefetch_related()` cache.
- To prevent possible loss of saved settings, `setup_test_environment()` now raises an exception if called a second time before calling `teardown_test_environment()`.
- The undocumented `DateTimeAwareJSONEncoder` alias for `DjangoJSONEncoder` (renamed in Django 1.0) is removed.
- The `cached template loader` is now enabled if `OPTIONS['loaders']` isn't specified and `OPTIONS['debug']` is `False` (the latter option defaults to the value of `DEBUG`). This could be backwards-incompatible if you have some [template tags that aren't thread safe](#).

- The prompt for stale content type deletion no longer occurs after running the `migrate` command. Use the new `remove_stale_contenttypes` command instead.
- The admin's widget for `IntegerField` uses `type="number"` rather than `type="text"`.
- Conditional HTTP headers are now parsed and compared according to the [RFC 7232](#) Conditional Requests specification rather than the older [RFC 2616](#).
- `patch_response_headers()` no longer adds a Last-Modified header. According to the [RFC 7234#section-4.2.2](#), this header is useless alongside other caching headers that provide an explicit expiration time, e.g. `Expires` or `Cache-Control`. `UpdateCacheMiddleware` and `add_never_cache_headers()` call `patch_response_headers()` and therefore are also affected by this change.
- In the admin templates, `<p class="help">` is replaced with a `<div>` tag to allow including lists inside help text.
- `ConditionalGetMiddleware` no longer sets the `Date` header as web servers set that header. It also no longer sets the `Content-Length` header as this is now done by `CommonMiddleware`.

If you have a middleware that modifies a response's content and appears before `CommonMiddleware` in the `MIDDLEWARE` or `MIDDLEWARE_CLASSES` settings, you must reorder your middleware so that responses aren't modified after `Content-Length` is set, or have the response modifying middleware reset the `Content-Length` header.

- `get_model()` and `get_models()` now raise `AppRegistryNotReady` if they're called before models of all applications have been loaded. Previously they only required the target application's models to be loaded and thus could return models without all their relations set up. If you need the old behavior of `get_model()`, set the `require_ready` argument to `False`.
- The unused `BaseCommand.can_import_settings` attribute is removed.
- The undocumented `django.utils.functional.lazy_property` is removed.
- For consistency with non-multipart requests, `MultiPartParser.parse()` now leaves `request.POST` immutable. If you're modifying that `QueryDict`, you must now first copy it, e.g. `request.POST.copy()`.
- Support for `cx_Oracle < 5.2` is removed.
- Support for `IPython < 1.0` is removed from the `shell` command.
- The signature of private `APIWidget.build_attrs()` changed from `extra_attrs=None, **kwargs` to `base_attrs, extra_attrs=None`.
- File-like objects (e.g., `StringIO` and `BytesIO`) uploaded to an `ImageField` using the test client now require a `name` attribute with a value that passes the `validate_image_file_extension` validator. See the note in `Client.post()`.
- `FileField` now moves rather than copies the file it receives. With the default file upload settings, files larger than `FILE_UPLOAD_MAX_MEMORY_SIZE` now have the same permissions as temporary files (often

0o600) rather than the system's standard umask (often 0o6644). Set the `FILE_UPLOAD_PERMISSIONS` if you need the same permission regardless of file size.

Features deprecated in 1.11

`models.permlink()` decorator

Use `django.urls.reverse()` instead. For example:

```
from django.db import models

class MyModel(models.Model):
    ...

    @models.permlink
    def url(self):
        return ("guitarist_detail", [self.slug])
```

becomes:

```
from django.db import models
from django.urls import reverse

class MyModel(models.Model):
    ...

    def url(self):
        return reverse("guitarist_detail", args=[self.slug])
```

Miscellaneous

- `contrib.auth`'s `login()` and `logout()` function-based views are deprecated in favor of new class-based views `LoginView` and `LogoutView`.
- The unused `extra_context` parameter of `contrib.auth.views.logout_then_login()` is deprecated.
- `contrib.auth`'s `password_change()`, `password_change_done()`, `password_reset()`, `password_reset_done()`, `password_reset_confirm()`, and `password_reset_complete()` function-based views are deprecated in favor of new class-based views `PasswordChangeView`, `PasswordChangeDoneView`, `PasswordResetView`, `PasswordResetDoneView`, `PasswordResetConfirmView`, and `PasswordResetCompleteView`.

- `django.test.runner.setup_databases()` is moved to `django.test.utils.setup_databases()`. The old location is deprecated.
- `django.utils.translation.string_concat()` is deprecated in favor of `django.utils.text.format_lazy()`. `string_concat(*strings)` can be replaced by `format_lazy('{}' * len(strings), *strings)`.
- For the PyLibMCCache cache backend, passing `pylibmc` behavior settings as top-level attributes of `OPTIONS` is deprecated. Set them under a `behaviors` key within `OPTIONS` instead.
- The `host` parameter of `django.utils.http.is_safe_url()` is deprecated in favor of the new `allowed_hosts` parameter.
- Silencing exceptions raised while rendering the `{% include %}` template tag is deprecated as the behavior is often more confusing than helpful. In Django 2.1, the exception will be raised.
- `DatabaseIntrospection.get_indexes()` is deprecated in favor of `DatabaseIntrospection.get_constraints()`.
- `authenticate()` now passes a `request` argument to the `authenticate()` method of authentication backends. Support for methods that don't accept `request` as the first positional argument will be removed in Django 2.1.
- The `USE_ETAGS` setting is deprecated in favor of `ConditionalGetMiddleware` which now adds the ETag header to responses regardless of the setting. `CommonMiddleware` and `django.utils.cache.patch_response_headers()` will no longer set ETags when the deprecation ends.
- `Model._meta.has_auto_field` is deprecated in favor of checking if `Model._meta.auto_field` is not `None`.
- Using regular expression groups with `%(?i)su#` in `url()` is deprecated. The only group that's useful is `(?i)` for case-insensitive URLs, however, case-insensitive URLs aren't a good practice because they create multiple entries for search engines, for example. An alternative solution could be to create a `handler404` that looks for uppercase characters in the URL and redirects to a lowercase equivalent.
- The `renderer` argument is added to the `Widget.render()` method. Methods that don't accept that argument will work through a deprecation period.

9.1.11 1.10 release

Django 1.10.8 release notes

September 5, 2017

Django 1.10.8 fixes a security issue in 1.10.7.

CVE-2017-12794: Possible XSS in traceback section of technical 500 debug page

In older versions, HTML autoescaping was disabled in a portion of the template for the technical 500 debug page. Given the right circumstances, this allowed a cross-site scripting attack. This vulnerability shouldn't affect most production sites since you shouldn't run with `DEBUG = True` (which makes this page accessible) in your production settings.

Django 1.10.7 release notes

April 4, 2017

Django 1.10.7 fixes two security issues and a bug in 1.10.6.

CVE-2017-7233: Open redirect and possible XSS attack via user-supplied numeric redirect URLs

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()` and [i18n](#)) to redirect the user to an “on success” URL. The security check for these redirects (namely `django.utils.http.is_safe_url()`) considered some numeric URLs (e.g. `http:999999999`) “safe” when they shouldn't be.

Also, if a developer relies on `is_safe_url()` to provide safe redirect targets and puts such a URL into a link, they could suffer from an XSS attack.

CVE-2017-7234: Open redirect vulnerability in `django.views.static.serve()`

A maliciously crafted URL to a Django site using the `serve()` view could redirect to any other domain. The view no longer does any redirects as they don't provide any known, useful functionality.

Note, however, that this view has always carried a warning that it is not hardened for production use and should be used only as a development aid.

Bugfixes

- Made admin's `RelatedFieldWidgetWrapper` use the wrapped widget's `value_omitted_from_data()` method ([#27905](#)).
- Fixed model form default fallback for `SelectMultiple` ([#27993](#)).

Django 1.10.6 release notes

March 1, 2017

Django 1.10.6 fixes several bugs in 1.10.5.

Bugfixes

- Fixed `ClearableFileInput`'s “Clear” checkbox on model form fields where the model field has a default ([#27805](#)).
- Fixed `RequestDataTooBig` and `TooManyFieldsSent` exceptions crashing rather than generating a bad request response ([#27820](#)).
- Fixed a crash on Oracle and PostgreSQL when subtracting `DurationField` or `IntegerField` from `DateField` ([#27828](#)).
- Fixed query expression date subtraction accuracy on PostgreSQL for differences larger than a month ([#27856](#)).
- Fixed a `GDALException` raised by `GDALClose` on `GDAL ≥ 2.0` ([#27479](#)).

Django 1.10.5 release notes

January 4, 2017

Django 1.10.5 fixes several bugs in 1.10.4.

Bugfixes

- Fixed a crash in the debug view if `request.user` can't be retrieved, such as if the database is unavailable ([#27567](#)).
- Fixed occasional missing plural forms in `JavaScriptCatalog` ([#27418](#)).
- Fixed a regression in the `timesince` and `timeuntil` filters that caused incorrect results for dates in a leap year ([#27637](#)).
- Fixed a regression where `collectstatic` overwrote newer files in remote storages ([#27658](#)).

Django 1.10.4 release notes

December 1, 2016

Django 1.10.4 fixes several bugs in 1.10.3.

Bugfixes

- Quoted the Oracle test user’s password in queries to fix the “ORA-00922: missing or invalid option” error when the password starts with a number or special character ([#27420](#)).
- Fixed incorrect `app_label` / `model_name` arguments for `allow_migrate()` in `makemigrations` migration consistency checks ([#27461](#)).
- Made `Model.delete(keep_parents=True)` preserve parent reverse relationships in multi-table inheritance ([#27407](#)).
- Fixed a `QuerySet.update()` crash on SQLite when updating a `DateTimeField` with an `F()` expression and a `timedelta` ([#27544](#)).
- Prevented `LocaleMiddleware` from redirecting on URLs that should return 404 when using `prefix_default_language=False` ([#27402](#)).
- Prevented an unnecessary index from being created on an InnoDB `ForeignKey` when the field was added after the model was created ([#27558](#)).

Django 1.10.3 release notes

November 1, 2016

Django 1.10.3 fixes two security issues and several bugs in 1.10.2.

User with hardcoded password created when running tests on Oracle

When running tests with an Oracle database, Django creates a temporary database user. In older versions, if a password isn’t manually specified in the database settings `TEST` dictionary, a hardcoded password is used. This could allow an attacker with network access to the database server to connect.

This user is usually dropped after the test suite completes, but not when using the `manage.py test --keepdb` option or if the user has an active session (such as an attacker’s connection).

A randomly generated password is now used for each test run.

DNS rebinding vulnerability when `DEBUG=True`

Older versions of Django don't validate the `Host` header against `settings.ALLOWED_HOSTS` when `settings.DEBUG=True`. This makes them vulnerable to a [DNS rebinding attack](#).

While Django doesn't ship a module that allows remote code execution, this is at least a cross-site scripting vector, which could be quite serious if developers load a copy of the production database in development or connect to some production services for which there's no development instance, for example. If a project uses a package like the `django-debug-toolbar`, then the attacker could execute arbitrary SQL, which could be especially bad if the developers connect to the database with a superuser account.

`settings.ALLOWED_HOSTS` is now validated regardless of `DEBUG`. For convenience, if `ALLOWED_HOSTS` is empty and `DEBUG=True`, the following variations of `localhost` are allowed `['localhost', '127.0.0.1', '::1']`. If your local settings file has your production `ALLOWED_HOSTS` value, you must now omit it to get those fallback values.

Bugfixes

- Allowed `User.is_authenticated` and `User.is_anonymous` properties to be tested for `set` membership ([#27309](#)).
- Fixed a performance regression when running `migrate` in projects with `RenameModel` operations ([#27279](#)).
- Added `model_name` to the `allow_migrate()` calls in `makemigrations` ([#27200](#)).
- Made the `JavaScriptCatalog` view respect the `packages` argument; previously it was ignored ([#27374](#)).
- Fixed `QuerySet.bulk_create()` on PostgreSQL when the number of objects is a multiple plus one of `batch_size` ([#27385](#)).
- Prevented `i18n_patterns()` from using too much of the URL as the language to fix a use case for `prefix_default_language=False` ([#27063](#)).
- Replaced a possibly incorrect redirect from `SessionMiddleware` when a session is destroyed in a concurrent request with a `SuspiciousOperation` to indicate that the request can't be completed ([#27363](#)).

Django 1.10.2 release notes

October 1, 2016

Django 1.10.2 fixes several bugs in 1.10.1.

Bugfixes

- Fixed a crash in MySQL database validation where `SELECT @@sql_mode` doesn't return a result (#27180).
- Allowed combining `contrib.postgres.search.SearchQuery` with more than one `&` or `|` operators (#27143).
- Disabled system check for URL patterns beginning with a `'/'` when `APPEND_SLASH=False` (#27238).
- Fixed model form default fallback for `CheckboxSelectMultiple`, `MultiWidget`, `FileInput`, `SplitDateTimeWidget`, `SelectDateWidget`, and `SplitArrayWidget` (#27186). Custom widgets affected by this issue should implement `value_omitted_from_data()`.
- Fixed a crash in `runserver` logging during a “Broken pipe” error (#27271).
- Fixed a regression where unchanged localized date/time fields were listed as changed in the admin's model history messages (#27302).

Django 1.10.1 release notes

September 1, 2016

Django 1.10.1 fixes several bugs in 1.10.

Bugfixes

- Fixed a crash in MySQL connections where `SELECT @@SQL_AUTO_IS_NULL` doesn't return a result (#26991).
- Allowed `User.is_authenticated` and `User.is_anonymous` properties to be compared using `==`, `!=`, and `|` (#26988, #27154).
- Removed the broken `BaseCommand.usage()` method which was for `optparse` support (#27000).
- Fixed a checks framework crash with an empty `Meta.default_permissions` (#26997).
- Fixed a regression in the number of queries when using `RadioSelect` with a `ModelChoiceField` form field (#27001).
- Fixed a crash if `request.META['CONTENT_LENGTH']` is an empty string (#27005).
- Fixed the `isnull` lookup on a `ForeignKey` with its `to_field` pointing to a `CharField` or pointing to a `CharField` defined with `primary_key=True` (#26983).
- Prevented the `migrate` command from raising `InconsistentMigrationHistory` in the presence of unapplied squashed migrations (#27004).
- Fixed a regression in `Client.force_login()` which required specifying a backend rather than automatically using the first one if multiple backends are configured (#27027).

- Made `QuerySet.bulk_create()` properly initialize model instances on backends, such as PostgreSQL, that support returning the IDs of the created records so that many-to-many relationships can be used on the new objects (#27026).
- Fixed crash of `django.views.static.serve()` with `show_indexes` enabled (#26973).
- Fixed `ClearableFileInput` to avoid the required HTML attribute when initial data exists (#27037).
- Fixed annotations with database functions when combined with lookups on PostGIS (#27014).
- Reallowed the `{% for %}` tag to unpack any iterable (#27058).
- Made `makemigrations` skip inconsistent history checks on non-default databases if database routers aren't in use or if no apps can be migrated to the database (#27054, #27110, #27142).
- Removed duplicated managers in `Model._meta.managers` (#27073).
- Fixed `contrib.admindocs` crash when a view is in a class, such as some of the admin views (#27018).
- Reverted a few admin checks that checked `field.many_to_many` back to `isinstance(field, models.ManyToManyField)` since it turned out the checks weren't suitable to be generalized like that (#26998).
- Added the database alias to the `InconsistentMigrationHistory` message raised by `makemigrations` and `migrate` (#27089).
- Fixed the creation of `ContentType` and `Permission` objects for models of applications without migrations when calling the `migrate` command with no migrations to apply (#27044).
- Included the already applied migration state changes in the `Apps` instance provided to the `pre_migrate` signal receivers to allow `ContentType` renaming to be performed on model rename (#27100).
- Reallowed subclassing `UserCreationForm` without `USERNAME_FIELD` in `Meta.fields` (#27111).
- Fixed a regression in model forms where model fields with a `default` that didn't appear in POST data no longer used the `default` (#27039).

Django 1.10 release notes

August 1, 2016

Welcome to Django 1.10!

These release notes cover the [new features](#), as well as some [backwards incompatible changes](#) you'll want to be aware of when upgrading from Django 1.9 or older versions. We've [dropped some features](#) that have reached the end of their deprecation cycle, and we've [begun the deprecation process](#) for some features.

See the [How to upgrade Django to a newer version](#) guide if you're updating an existing project.

Python compatibility

Like Django 1.9, Django 1.10 requires Python 2.7, 3.4, or 3.5. We highly recommend and only officially support the latest release of each series.

What's new in Django 1.10

Full text search for PostgreSQL

`django.contrib.postgres` now includes a [collection of database functions](#) to allow the use of the full text search engine. You can search across multiple fields in your relational database, combine the searches with other lookups, use different language configurations and weightings, and rank the results by relevance.

It also now includes trigram support, using the `trigram_similar` lookup, and the `TrigramSimilarity` and `TrigramDistance` expressions.

New-style middleware

A new style of [middleware](#) is introduced to solve the lack of strict request/response layering of the old-style of middleware described in [DEP 0005](#). You'll need to [adapt old, custom middleware](#) and switch from the `MIDDLEWARE_CLASSES` setting to the new `MIDDLEWARE` setting to take advantage of the improvements.

Official support for Unicode usernames

The `User` model in `django.contrib.auth` originally only accepted ASCII letters and numbers in usernames. Although it wasn't a deliberate choice, Unicode characters have always been accepted when using Python 3.

The username validator now explicitly accepts Unicode characters by default on Python 3 only.

Custom user models may use the new `ASCIIUsernameValidator` or `UnicodeUsernameValidator`.

Minor features

`django.contrib.admin`

- For sites running on a subpath, the default [URL for the "View site" link](#) at the top of each admin page will now point to `request.META['SCRIPT_NAME']` if set, instead of `/`.
- The success message that appears after adding or editing an object now contains a link to the object's change form.

- All inline JavaScript is removed so you can enable the Content-Security-Policy HTTP header if you wish.
- The new `InlineModelAdmin.classes` attribute allows specifying classes on inline fieldsets. Inlines with a `collapse` class will be initially collapsed and their header will have a small “show” link.
- If a user doesn’t have the add permission, the `object-tools` block on a model’s changelist will now be rendered (without the add button). This makes it easier to add custom tools in this case.
- The `LogEntry` model now stores change messages in a JSON structure so that the message can be dynamically translated using the current active language. A new `LogEntry.get_change_message()` method is now the preferred way of retrieving the change message.
- Selected objects for fields in `ModelAdmin.raw_id_fields` now have a link to object’s change form.
- Added “No date” and “Has date” choices for `DateFieldListFilter` if the field is nullable.
- The jQuery library embedded in the admin is upgraded from version 2.1.4 to 2.2.3.

`django.contrib.auth`

- Added support for the `Argon2 password hash`. It’s recommended over PBKDF2, however, it’s not the default as it requires a third-party library.
- The default iteration count for the PBKDF2 password hasher has been increased by 25%. This backwards compatible change will not affect users who have subclassed `django.contrib.auth.hashers.PBKDF2PasswordHasher` to change the default value.
- The `django.contrib.auth.views.logout()` view sends “no-cache” headers to prevent an issue where Safari caches redirects and prevents a user from being able to log out.
- Added the optional `backend` argument to `django.contrib.auth.login()` to allow using it without credentials.
- The new `LOGOUT_REDIRECT_URL` setting controls the redirect of the `django.contrib.auth.views.logout()` view, if the view doesn’t get a `next_page` argument.
- The new `redirect_authenticated_user` parameter for the `django.contrib.auth.views.login()` view allows redirecting authenticated users visiting the login page.
- The new `AllowAllUsersModelBackend` and `AllowAllUsersRemoteUserBackend` ignore the value of `User.is_active`, while `ModelBackend` and `RemoteUserBackend` now reject inactive users.

`django.contrib.gis`

- Distance lookups now accept expressions as the distance value parameter.
- The new `GEOSGeometry.unary_union` property computes the union of all the elements of this geometry.
- Added the `GEOSGeometry.covers()` binary predicate.
- Added the `GDALBand.statistics()` method and `mean` and `std` attributes.
- Added support for the `MakeLine` aggregate and `GeoHash` function on Spatialite.
- Added support for the `Difference`, `Intersection`, and `SymDifference` functions on MySQL.
- Added support for instantiating empty GEOS geometries.
- The new `trim` and `precision` properties of `WKTWriter` allow controlling output of the fractional part of the coordinates in WKT.
- Added the `LineString.closed` and `MultiLineString.closed` properties.
- The GeoJSON serializer now outputs the primary key of objects in the `properties` dictionary if specific fields aren't specified.
- The ability to replicate input data on the `GDALBand.data()` method was added. Band data can now be updated with repeated values efficiently.
- Added database functions `IsValid` and `MakeValid`, as well as the `isvalid` lookup, all for PostGIS. This allows filtering and repairing invalid geometries on the database side.
- Added raster support for all spatial lookups.

`django.contrib.postgres`

- For convenience, `HStoreField` now casts its keys and values to strings.

`django.contrib.sessions`

- The `clearsessions` management command now removes file-based sessions.

`django.contrib.sites`

- The *Site* model now supports [natural keys](#).

`django.contrib.staticfiles`

- The *static* template tag now uses `django.contrib.staticfiles` if it's in `INSTALLED_APPS`. This is especially useful for third-party apps which can now always use `{% load static %}` (instead of `{% load staticfiles %}` or `{% load static from staticfiles %}`) and not worry about whether or not the `staticfiles` app is installed.
- You can [more easily customize](#) the `collectstatic --ignore` option with a custom `AppConfig`.

Cache

- The file-based cache backend now uses the highest pickling protocol.

CSRF

- The default *CSRF_FAILURE_VIEW*, `views.csrf.csrf_failure()` now accepts an optional `template_name` parameter, defaulting to `'403_csrf.html'`, to control the template used to render the page.
- To protect against *BREACH* attacks, the CSRF protection mechanism now changes the form token value on every request (while keeping an invariant secret which can be used to validate the different tokens).

Database backends

- Temporal data subtraction was unified on all backends.
- If the database supports it, backends can set `DatabaseFeatures.can_return_ids_from_bulk_insert=True` and implement `DatabaseOperations.fetch_returned_insert_ids()` to set primary keys on objects created using `QuerySet.bulk_create()`.
- Added keyword arguments to the `as_sql()` methods of various expressions (`Func`, `When`, `Case`, and `OrderBy`) to allow database backends to customize them without mutating `self`, which isn't safe when using different database backends. See the `arg_joiner` and `**extra_context` parameters of *Func.as_sql()* for an example.

File Storage

- Storage backends now present a timezone-aware API with new methods `get_accessed_time()`, `get_created_time()`, and `get_modified_time()`. They return a timezone-aware `datetime` if `USE_TZ` is `True` and a naive `datetime` in the local timezone otherwise.
- The new `Storage.generate_filename()` method makes it easier to implement custom storages that don't use the `os.path` calls previously in `FileField`.

Forms

- Form and widget Media is now served using `django.contrib.staticfiles` if installed.
- The `<input>` tag rendered by `CharField` now includes a `minlength` attribute if the field has a `min_length`.
- Required form fields now have the `required` HTML attribute. Set the new `Form.use_required_attribute` attribute to `False` to disable it. The `required` attribute isn't included on forms of formsets because the browser validation may not be correct when adding and deleting formsets.

Generic Views

- The `View` class can now be imported from `django.views`.

Internationalization

- The `i18n_patterns()` helper function can now be used in a root `URLConf` specified using `request.urlconf`.
- By setting the new `prefix_default_language` parameter for `i18n_patterns()` to `False`, you can allow accessing the default language without a URL prefix.
- `set_language()` now returns a 204 status code (No Content) for AJAX requests when there is no `next` parameter in POST or GET.
- The `JavaScriptCatalog` and `JSONCatalog` class-based views supersede the deprecated `javascript_catalog()` and `json_catalog()` function-based views. The new views are almost equivalent to the old ones except that by default the new views collect all JavaScript strings in the `djangojs` translation domain from all installed apps rather than only the JavaScript strings from `LOCALE_PATHS`.

Management Commands

- `call_command()` now returns the value returned from the `command.handle()` method.
- The new `check --fail-level` option allows specifying the message level that will cause the command to exit with a non-zero status.
- The new `makemigrations --check` option makes the command exit with a non-zero status when model changes without migrations are detected.
- `makemigrations` now displays the path to the migration files that it generates.
- The `shell --interface` option now accepts `python` to force use of the “plain” Python interpreter.
- The new `shell --command` option lets you run a command as Django and exit, instead of opening the interactive shell.
- Added a warning to `dumpdata` if a proxy model is specified (which results in no output) without its concrete parent.
- The new `BaseCommand.requires_migrations_checks` attribute may be set to `True` if you want your command to print a warning, like `runserver` does, if the set of migrations on disk don't match the migrations in the database.
- To assist with testing, `call_command()` now accepts a command object as the first argument.
- The `shell` command supports tab completion on systems using `libedit`, e.g. macOS.
- The `inspectdb` command lets you choose what tables should be inspected by specifying their names as arguments.

Migrations

- Added support for serialization of `enum.Enum` objects.
- Added the `elidable` argument to the `RunSQL` and `RunPython` operations to allow them to be removed when squashing migrations.
- Added support for `non-atomic migrations` by setting the `atomic` attribute on a `Migration`.
- The `migrate` and `makemigrations` commands now `check for a consistent migration history`. If they find some unapplied dependencies of an applied migration, `InconsistentMigrationHistory` is raised.
- The `pre_migrate()` and `post_migrate()` signals now dispatch their migration plan and apps.

Models

- Reverse foreign keys from proxy models are now propagated to their concrete class. The reverse relation attached by a *ForeignKey* pointing to a proxy model is now accessible as a descriptor on the proxied model class and may be referenced in queryset filtering.
- The new *Field.rel_db_type()* method returns the database column data type for fields such as *ForeignKey* and *OneToOneField* that point to another field.
- The *arity* class attribute is added to *Func*. This attribute can be used to set the number of arguments the function accepts.
- Added *BigAutoField* which acts much like an *AutoField* except that it is guaranteed to fit numbers from 1 to 9223372036854775807.
- *QuerySet.in_bulk()* may be called without any arguments to return all objects in the queryset.
- *related_query_name* now supports app label and class interpolation using the `'%(app_label)s'` and `'%(class)s'` strings.
- Allowed overriding model fields inherited from abstract base classes.
- The *prefetch_related_objects()* function is now a public API.
- *QuerySet.bulk_create()* sets the primary key on objects when using PostgreSQL.
- Added the *Cast* database function.
- A proxy model may now inherit multiple proxy models that share a common non-abstract parent class.
- Added *Extract* functions to extract datetime components as integers, such as year and hour.
- Added *Trunc* functions to truncate a date or datetime to a significant component. They enable queries like sales-per-day or sales-per-hour.
- *Model.__init__()* now sets values of virtual fields from its keyword arguments.
- The new *Meta.base_manager_name* and *Meta.default_manager_name* options allow controlling the *_base_manager* and *_default_manager*, respectively.

Requests and Responses

- Added *request.user* to the debug view.
- Added *HttpResponse* methods *readable()* and *seekable()* to make an instance a stream-like object and allow wrapping it with *io.TextIOWrapper*.
- Added the *HttpRequest.content_type* and *content_params* attributes which are parsed from the *CONTENT_TYPE* header.

- The parser for `request.COOKIES` is simplified to better match the behavior of browsers. `request.COOKIES` may now contain cookies that are invalid according to [RFC 6265](#) but are possible to set via `document.cookie`.

Serialization

- The `django.core.serializers.json.DjangoJSONEncoder` now knows how to serialize lazy strings, typically used for translatable content.

Templates

- Added the `autoescape` option to the *DjangoTemplates* backend and the *Engine* class.
- Added the `is` and `is not` comparison operators to the *if* tag.
- Allowed *dictsort* to order a list of lists by an element at a specified index.
- The *debug()* context processor contains queries for all database aliases instead of only the default alias.
- Added relative path support for string arguments of the *extends* and *include* template tags.

Tests

- To better catch bugs, *TestCase* now checks deferrable database constraints at the end of each test.
- Tests and test cases can be [marked with tags](#) and run selectively with the new `test --tag` and `test --exclude-tag` options.
- You can now login and use sessions with the test client even if *django.contrib.sessions* is not in *INSTALLED_APPS*.

URLs

- An addition in *django.setup()* allows URL resolving that happens outside of the request/response cycle (e.g. in management commands and standalone scripts) to take *FORCE_SCRIPT_NAME* into account when it is set.

Validators

- `URLValidator` now limits the length of domain name labels to 63 characters and the total length of domain names to 253 characters per [RFC 1034](#).
- `int_list_validator()` now accepts an optional `allow_negative` boolean parameter, defaulting to `False`, to allow negative integers.

Backwards incompatible changes in 1.10

Warning: In addition to the changes outlined in this section, be sure to review the [Features removed in 1.10](#) for the features that have reached the end of their deprecation cycle and therefore been removed. If you haven't updated your code within the deprecation timeline for a given feature, its removal may appear as a backwards incompatible change.

Database backend API

- GIS' s `AreaField` uses an unspecified underlying numeric type that could in practice be any numeric Python type. `decimal.Decimal` values retrieved from the database are now converted to `float` to make it easier to combine them with values used by the GIS libraries.
- In order to enable temporal subtraction you must set the `supports_temporal_subtraction` database feature flag to `True` and implement the `DatabaseOperations.subtract_temporals()` method. This method should return the SQL and parameters required to compute the difference in microseconds between the `lhs` and `rhs` arguments in the datatype used to store `DurationField`.

`select_related()` prohibits non-relational fields for nested relations

Django 1.8 added validation for non-relational fields in `select_related()`:

```
>>> Book.objects.select_related("title")
Traceback (most recent call last):
...
FieldError: Non-relational field given in select_related: 'title'
```

But it didn't prohibit nested non-relation fields as it does now:

```
>>> Book.objects.select_related("author__name")
Traceback (most recent call last):
...
FieldError: Non-relational field given in select_related: 'name'
```

`_meta.get_fields()` returns consistent reverse fields for proxy models

Before Django 1.10, the `get_fields()` method returned different reverse fields when called on a proxy model compared to its proxied concrete class. This inconsistency was fixed by returning the full set of fields pointing to a concrete class or one of its proxies in both cases.

`AbstractUser.username` max_length increased to 150

A migration for `django.contrib.auth.models.User.username` is included. If you have a custom user model inheriting from `AbstractUser`, you'll need to generate and apply a database migration for your user model.

We considered an increase to 254 characters to more easily allow the use of email addresses (which are limited to 254 characters) as usernames but rejected it due to a MySQL limitation. When using the `utf8mb4` encoding (recommended for proper Unicode support), MySQL can only create unique indexes with 191 characters by default. Therefore, if you need a longer length, please use a custom user model.

If you want to preserve the 30 character limit for usernames, use a custom form when creating a user or changing usernames:

```
from django.contrib.auth.forms import UserCreationForm

class MyUserCreationForm(UserCreationForm):
    username = forms.CharField(
        max_length=30,
        help_text="Required. 30 characters or fewer. Letters, digits and @/./+/-/_ only.",
    )
```

If you wish to keep this restriction in the admin, set `UserAdmin.add_form` to use this form:

```
from django.contrib.auth.admin import UserAdmin as BaseUserAdmin
from django.contrib.auth.models import User

class UserAdmin(BaseUserAdmin):
    add_form = MyUserCreationForm

admin.site.unregister(User)
admin.site.register(User, UserAdmin)
```

Dropped support for PostgreSQL 9.1

Upstream support for PostgreSQL 9.1 ends in September 2016. As a consequence, Django 1.10 sets PostgreSQL 9.2 as the minimum version it officially supports.

runserver output goes through logging

Request and response handling of the `runserver` command is sent to the `django.server` logger instead of to `sys.stderr`. If you disable Django's logging configuration or override it with your own, you'll need to add the appropriate logging configuration if you want to see that output:

```
LOGGING = {
    # ...
    "formatters": {
        "django.server": {
            "()": "django.utils.log.ServerFormatter",
            "format": "%(server_time)s %(message)s",
        }
    },
    "handlers": {
        "django.server": {
            "level": "INFO",
            "class": "logging.StreamHandler",
            "formatter": "django.server",
        },
    },
    "loggers": {
        "django.server": {
            "handlers": ["django.server"],
            "level": "INFO",
            "propagate": False,
        }
    },
}
```

auth.CustomUser and auth.ExtensionUser test models were removed

Since the introduction of migrations for the contrib apps in Django 1.8, the tables of these custom user test models were not created anymore making them unusable in a testing context.

Apps registry is no longer auto-populated when unpickling models outside of Django

The apps registry is no longer auto-populated when unpickling models. This was added in Django 1.7.2 as an attempt to allow unpickling models outside of Django, such as in an RQ worker, without calling `django.setup()`, but it creates the possibility of a deadlock. To adapt your code in the case of RQ, you can [provide your own worker script](#) that calls `django.setup()`.

Removed null assignment check for non-null foreign key fields

In older versions, assigning `None` to a non-nullable `ForeignKey` or `OneToOneField` raised `ValueError('Cannot assign None: "model.field" does not allow null values.')`. For consistency with other model fields which don't have a similar check, this check is removed.

Removed weak password hashers from the default `PASSWORD_HASHERS` setting

Django 0.90 stored passwords as unsalted MD5. Django 0.91 added support for salted SHA1 with automatic upgrade of passwords when a user logs in. Django 1.4 added PBKDF2 as the default password hasher.

If you have an old Django project with MD5 or SHA1 (even salted) encoded passwords, be aware that these can be cracked fairly easily with today's hardware. To make Django users acknowledge continued use of weak hashers, the following hashers are removed from the default `PASSWORD_HASHERS` setting:

```
"django.contrib.auth.hashers.SHA1PasswordHasher"
"django.contrib.auth.hashers.MD5PasswordHasher"
"django.contrib.auth.hashers.UnsaltedSHA1PasswordHasher"
"django.contrib.auth.hashers.UnsaltedMD5PasswordHasher"
"django.contrib.auth.hashers.CryptPasswordHasher"
```

Consider using a [wrapped password hasher](#) to strengthen the hashes in your database. If that's not feasible, add the `PASSWORD_HASHERS` setting to your project and add back any hashers that you need.

You can check if your database has any of the removed hashers like this:

```
from django.contrib.auth import get_user_model

User = get_user_model()

# Unsalted MD5/SHA1:
User.objects.filter(password__startswith="md5$$")
User.objects.filter(password__startswith="sha1$$")
# Salted MD5/SHA1:
User.objects.filter(password__startswith="md5$").exclude(password__startswith="md5$$")
User.objects.filter(password__startswith="sha1$").exclude(password__startswith="sha1$$")
```

(continues on next page)

(continued from previous page)

```
# Crypt hasher:
User.objects.filter(password__startswith="crypt$$")

from django.db.models import CharField
from django.db.models.functions import Length

CharField.register_lookup(Length)
# Unsalted MD5 passwords might not have an 'md5$$' prefix:
User.objects.filter(password__length=32)
```

`Field.get_prep_lookup()` and `Field.get_db_prep_lookup()` methods are removed

If you have a custom field that implements either of these methods, register a custom lookup for it. For example:

```
from django.db.models import Field
from django.db.models.lookups import Exact

class MyField(Field):
    ...

class MyFieldExact(Exact):
    def get_prep_lookup(self):
        # do_custom_stuff_for_myfield
        ...

MyField.register_lookup(MyFieldExact)
```

`django.contrib.gis`

- Support for SpatiaLite < 3.0 and GEOS < 3.3 is dropped.
- The `add_postgis_srs()` backwards compatibility alias for `django.contrib.gis.utils.add_srs_entry()` is removed.
- On Oracle/GIS, the `Area` aggregate function now returns a float instead of `decimal.Decimal`. (It's still wrapped in a measure of square meters.)
- The default `GEOSGeometry` representation (WKT output) is trimmed by default. That is, instead of `POINT (23.000000000000000 5.500000000000000)`, you'll get `POINT (23 5.5)`.

Maximum size of a request body and the number of GET/POST parameters is limited

Two new settings help mitigate denial-of-service attacks via large requests:

- `DATA_UPLOAD_MAX_MEMORY_SIZE` limits the size that a request body may be. File uploads don't count toward this limit.
- `DATA_UPLOAD_MAX_NUMBER_FIELDS` limits the number of GET/POST parameters that are parsed.

Applications that receive unusually large form posts may need to tune these settings.

Miscellaneous

- The `repr()` of a `QuerySet` is wrapped in `<QuerySet>` to disambiguate it from a plain list when debugging.
- `utils.version.get_version()` returns PEP 440 compliant release candidate versions (e.g. `'1.10rc1'` instead of `'1.10c1'`).
- CSRF token values are now required to be strings of 64 alphanumerics; values of 32 alphanumerics, as set by older versions of Django by default, are automatically replaced by strings of 64 characters. Other values are considered invalid. This should only affect developers or users who replace these tokens.
- The `LOGOUT_URL` setting is removed as Django hasn't made use of it since pre-1.0. If you use it in your project, you can add it to your project's settings. The default value was `'/accounts/logout/'`.
- Objects with a `close()` method such as files and generators passed to `HttpResponse` are now closed immediately instead of when the WSGI server calls `close()` on the response.
- A redundant `transaction.atomic()` call in `QuerySet.update_or_create()` is removed. This may affect query counts tested by `TransactionTestCase.assertNumQueries()`.
- Support for `skip_validation` in `BaseCommand.execute(**options)` is removed. Use `skip_checks` (added in Django 1.7) instead.
- `loaddata` now raises a `CommandError` instead of showing a warning when the specified fixture file is not found.
- Instead of directly accessing the `LogEntry.change_message` attribute, it's now better to call the `LogEntry.get_change_message()` method which will provide the message in the current language.
- The default error views now raise `TemplateDoesNotExist` if a nonexistent `template_name` is specified.
- The unused `choices` keyword argument of the `Select` and `SelectMultiple` widgets' `render()` method is removed. The `choices` argument of the `render_options()` method is also removed, making `selected_choices` the first argument.
- Tests that violate deferrable database constraints will now error when run on a database that supports deferrable constraints.

- Built-in management commands now use indexing of keys in `options`, e.g. `options['verbosity']`, instead of `options.get()` and no longer perform any type coercion. This could be a problem if you're calling commands using `Command.execute()` (which bypasses the argument parser that sets a default value) instead of `call_command()`. Instead of calling `Command.execute()`, pass the command object as the first argument to `call_command()`.
- `ModelBackend` and `RemoteUserBackend` now reject inactive users. This means that inactive users can't login and will be logged out if they are switched from `is_active=True` to `False`. If you need the previous behavior, use the new `AllowAllUsersModelBackend` or `AllowAllUsersRemoteUserBackend` in `AUTHENTICATION_BACKENDS` instead.
- In light of the previous change, the test client's `login()` method no longer always rejects inactive users but instead delegates this decision to the authentication backend. `force_login()` also delegates the decision to the authentication backend, so if you're using the default backends, you need to use an active user.
- `django.views.i18n.set_language()` may now return a 204 status code for AJAX requests.
- The `base_field` attribute of `RangeField` is now a type of field, not an instance of a field. If you have created a custom subclass of `RangeField`, you should change the `base_field` attribute.
- Middleware classes are now initialized when the server starts rather than during the first request.
- If you override `is_authenticated()` or `is_anonymous()` in a custom user model, you must convert them to attributes or properties as described in [the deprecation note](#).
- When using `ModelAdmin.save_as=True`, the “Save as new” button now redirects to the change view for the new object instead of to the model's changelist. If you need the previous behavior, set the new `ModelAdmin.save_as_continue` attribute to `False`.
- Required form fields now have the `required` HTML attribute. Set the `Form.use_required_attribute` attribute to `False` to disable it. You could also add the `novalidate` attribute to `<form>` if you don't want browser validation. To disable the `required` attribute on custom widgets, override the `Widget.use_required_attribute()` method.
- The WSGI handler no longer removes content of responses from HEAD requests or responses with a `status_code` of 100-199, 204, or 304. Most web servers already implement this behavior. Responses retrieved using the Django test client continue to have these “response fixes” applied.
- `Model.__init__()` now receives `django.db.models.DEFERRED` as the value of deferred fields.
- The `Model._deferred` attribute is removed as dynamic model classes when using `QuerySet.defer()` and `only()` is removed.
- `Storage.save()` no longer replaces `'\'` with `'/'`. This behavior is moved to `FileSystemStorage` since this is a storage specific implementation detail. Any Windows user with a custom storage implementation that relies on this behavior will need to implement it in the custom storage's `save()` method.
- Private `FileField` methods `get_directory_name()` and `get_filename()` are no longer called (and are now deprecated) which is a backwards incompatible change for users overriding those meth-

ods on custom fields. To adapt such code, override `FileField.generate_filename()` or `Storage.generate_filename()` instead. It might be possible to use `upload_to` also.

- The subject of mail sent by `AdminEmailHandler` is no longer truncated at 989 characters. If you were counting on a limited length, truncate the subject yourself.
- Private expressions `django.db.models.expressions.Date` and `DateTime` are removed. The new `Trunc` expressions provide the same functionality.
- The `_base_manager` and `_default_manager` attributes are removed from model instances. They remain accessible on the model class.
- Accessing a deleted field on a model instance, e.g. after `del obj.field`, reloads the field's value instead of raising `AttributeError`.
- If you subclass `AbstractBaseUser` and override `clean()`, be sure it calls `super()`. `AbstractBaseUser.normalize_username()` is called in a new `AbstractBaseUser.clean()` method.
- Private API `django.forms.models.model_to_dict()` returns a queryset rather than a list of primary keys for `ManyToManyFields`.
- If `django.contrib.staticfiles` is installed, the `static` template tag uses the `staticfiles` storage to construct the URL rather than simply joining the value with `STATIC_ROOT`. The new approach encodes the URL, which could be backwards-incompatible in cases such as including a fragment in a path, e.g. `{% static 'img.svg#fragment' %}`, since the `#` is encoded as `%23`. To adapt, move the fragment outside the template tag: `{% static 'img.svg' %}#fragment`.
- When `USE_L10N` is `True`, localization is now applied for the `date` and `time` filters when no format string is specified. The `DATE_FORMAT` and `TIME_FORMAT` specifiers from the active locale are used instead of the settings of the same name.

Features deprecated in 1.10

Direct assignment to a reverse foreign key or many-to-many relation

Instead of assigning related objects using direct assignment:

```
>>> new_list = [obj1, obj2, obj3]
>>> e.related_set = new_list
```

Use the `set()` method added in Django 1.9:

```
>>> e.related_set.set([obj1, obj2, obj3])
```

This prevents confusion about an assignment resulting in an implicit save.

Non-timezone-aware Storage API

The old, non-timezone-aware methods `accessed_time()`, `created_time()`, and `modified_time()` are deprecated in favor of the new `get*_time()` methods.

Third-party storage backends should implement the new methods and mark the old ones as deprecated. Until then, the new `get*_time()` methods on the base `Storage` class convert `datetimes` from the old methods as required and emit a deprecation warning as they do so.

Third-party storage backends may retain the old methods as long as they wish to support earlier versions of Django.

`django.contrib.gis`

- The `get_srid()` and `set_srid()` methods of `GEOSGeometry` are deprecated in favor of the `srid` property.
- The `get_x()`, `set_x()`, `get_y()`, `set_y()`, `get_z()`, and `set_z()` methods of `Point` are deprecated in favor of the `x`, `y`, and `z` properties.
- The `get_coords()` and `set_coords()` methods of `Point` are deprecated in favor of the `tuple` property.
- The `cascaded_union` property of `MultiPolygon` is deprecated in favor of the `unary_union` property.
- The `django.contrib.gis.utils.precision_wkt()` function is deprecated in favor of `WKTWriter`.

`CommaSeparatedIntegerField` model field

`CommaSeparatedIntegerField` is deprecated in favor of `CharField` with the `validate_comma_separated_integer_list()` validator:

```
from django.core.validators import validate_comma_separated_integer_list
from django.db import models

class MyModel(models.Model):
    numbers = models.CharField(..., validators=[validate_comma_separated_integer_list])
```

If you're using Oracle, `CharField` uses a different database field type (`NVARCHAR2`) than `CommaSeparatedIntegerField` (`VARCHAR2`). Depending on your database settings, this might imply a different encoding, and thus a different length (in bytes) for the same contents. If your stored values are longer than the 4000 byte limit of `NVARCHAR2`, you should use `TextField` (`NCLOB`) instead. In this case, if you have any queries that group by the field (e.g. annotating the model with an aggregation or using `distinct()`) you'll need to change them (to defer the field).

Using a model name as a query lookup when `default_related_name` is set

Assume the following models:

```
from django.db import models

class Foo(models.Model):
    pass

class Bar(models.Model):
    foo = models.ForeignKey(Foo)

    class Meta:
        default_related_name = "bars"
```

In older versions, `default_related_name` couldn't be used as a query lookup. This is fixed and support for the old lookup name is deprecated. For example, since `default_related_name` is set in model `Bar`, instead of using the model name `bar` as the lookup:

```
>>> bar = Bar.objects.get(pk=1)
>>> Foo.objects.get(bar=bar)
```

use the `default_related_name` `bars`:

```
>>> Foo.objects.get(bars=bar)
```

`__search` query lookup

The `search` lookup, which supports MySQL only and is extremely limited in features, is deprecated. Replace it with a custom lookup:

```
from django.db import models

class Search(models.Lookup):
    lookup_name = "search"

    def as_mysql(self, compiler, connection):
        lhs, lhs_params = self.process_lhs(compiler, connection)
        rhs, rhs_params = self.process_rhs(compiler, connection)
        params = lhs_params + rhs_params
        return "MATCH (%s) AGAINST (%s IN BOOLEAN MODE)" % (lhs, rhs), params
```

(continues on next page)

(continued from previous page)

```
models.CharField.register_lookup(Search)
models.TextField.register_lookup(Search)
```

Using `User.is_authenticated()` and `User.is_anonymous()` as methods

The `is_authenticated()` and `is_anonymous()` methods of `AbstractBaseUser` and `AnonymousUser` classes are now properties. They will still work as methods until Django 2.0, but all usage in Django now uses attribute access.

For example, if you use `AuthenticationMiddleware` and want to know whether the user is currently logged-in you would use:

```
if request.user.is_authenticated:
    ... # Do something for logged-in users.
else:
    ... # Do something for anonymous users.
```

instead of `request.user.is_authenticated()`.

This change avoids accidental information leakage if you forget to call the method, e.g.:

```
if request.user.is_authenticated:
    return sensitive_information
```

If you override these methods in a custom user model, you must change them to properties or attributes.

Django uses a `CallableBool` object to allow these attributes to work as both a property and a method. Thus, until the deprecation period ends, you cannot compare these properties using the `is` operator. That is, the following won't work:

```
if request.user.is_authenticated is True:
    ...
```

Custom manager classes available through `prefetch_related` must define a `_apply_rel_filters()` method

If you defined a custom manager class available through `prefetch_related()` you must make sure it defines a `_apply_rel_filters()` method.

This method must accept a `QuerySet` instance as its single argument and return a filtered version of the queryset for the model instance the manager is bound to.

The “escape” half of `django.utils.safestring`

The `mark_for_escaping()` function and the classes it uses: `EscapeData`, `EscapeBytes`, `EscapeText`, `EscapeString`, and `EscapeUnicode` are deprecated.

As a result, the “lazy” behavior of the `escape` filter (where it would always be applied as the last filter no matter where in the filter chain it appeared) is deprecated. The filter will change to immediately apply `conditional_escape()` in Django 2.0.

`Manager.use_for_related_fields` and inheritance changes

`Manager.use_for_related_fields` is deprecated in favor of setting `Meta.base_manager_name` on the model.

Model `Manager` inheritance will follow MRO inheritance rules in Django 2.0, changing the current behavior where managers defined on non-abstract base classes aren’t inherited by child classes. A deprecating warning with instructions on how to adapt your code is raised if you have any affected managers. You’ll either redeclare a manager from an abstract model on the child class to override the manager from the concrete model, or you’ll set the model’s `Meta.manager_inheritance_from_future=True` option to opt-in to the new inheritance behavior.

During the deprecation period, `use_for_related_fields` will be honored and raise a warning, even if a `base_manager_name` is set. This allows third-party code to preserve legacy behavior while transitioning to the new API. The warning can be silenced by setting `silence_use_for_related_fields_deprecation=True` on the manager.

Miscellaneous

- The `makemigrations --exit` option is deprecated in favor of the `makemigrations --check` option.
- `django.utils.functional.allow_lazy()` is deprecated in favor of the new `keep_lazy()` function which can be used with a more natural decorator syntax.
- The `shell --plain` option is deprecated in favor of `-i python` or `--interface python`.
- Importing from the `django.core.urlresolvers` module is deprecated in favor of its new location, `django.urls`.
- The template `Context.has_key()` method is deprecated in favor of `in`.
- The private attribute `virtual_fields` of `Model._meta` is deprecated in favor of `private_fields`.
- The private keyword arguments `virtual_only` in `Field.contribute_to_class()` and `virtual` in `Model._meta.add_field()` are deprecated in favor of `private_only` and `private`, respectively.
- The `javascript_catalog()` and `json_catalog()` views are deprecated in favor of class-based views `JavaScriptCatalog` and `JSONCatalog`.

- In multi-table inheritance, implicit promotion of a `OneToOneField` to a `parent_link` is deprecated. Add `parent_link=True` to such fields.
- The private API `Widget._format_value()` is made public and renamed to `format_value()`. The old name will work through a deprecation period.
- Private `FileField` methods `get_directory_name()` and `get_filename()` are deprecated in favor of performing this work in `Storage.generate_filename()`.
- Old-style middleware that uses `settings.MIDDLEWARE_CLASSES` are deprecated. Adapt old, custom middleware and use the new `MIDDLEWARE` setting.

Features removed in 1.10

These features have reached the end of their deprecation cycle and are removed in Django 1.10. See [Features deprecated in 1.8](#) for details, including how to remove usage of these features.

- Support for calling a `SQLCompiler` directly as an alias for calling its `quote_name_unless_alias` method is removed.
- The `cycle` and `firstof` template tags are removed from the `future` template tag library.
- `django.conf.urls.patterns()` is removed.
- Support for the `prefix` argument to `django.conf.urls.i18n.i18n_patterns()` is removed.
- `SimpleTestCase.urls` is removed.
- Using an incorrect count of unpacked values in the `for` template tag raises an exception rather than failing silently.
- The ability to `reverse()` URLs using a dotted Python path is removed.
- The ability to use a dotted Python path for the `LOGIN_URL` and `LOGIN_REDIRECT_URL` settings is removed.
- Support for `optparse` is dropped for custom management commands.
- The class `django.core.management.NoArgsCommand` is removed.
- `django.core.context_processors` module is removed.
- `django.db.models.sql.aggregates` module is removed.
- `django.contrib.gis.db.models.sql.aggregates` module is removed.
- The following methods and properties of `django.db.sql.query.Query` are removed:
 - Properties: `aggregates` and `aggregate_select`
 - Methods: `add_aggregate`, `set_aggregate_mask`, and `append_aggregate_mask`.
- `django.template.resolve_variable` is removed.

- The following private APIs are removed from `django.db.models.options.Options` (`Model._meta`):
 - `get_field_by_name()`
 - `get_all_field_names()`
 - `get_fields_with_model()`
 - `get_concrete_fields_with_model()`
 - `get_m2m_with_model()`
 - `get_all_related_objects()`
 - `get_all_related_objects_with_model()`
 - `get_all_related_many_to_many_objects()`
 - `get_all_related_m2m_objects_with_model()`
- The `error_message` argument of `django.forms.RegexField` is removed.
- The `unordered_list` filter no longer supports old style lists.
- Support for string view arguments to `url()` is removed.
- The backward compatible shim to rename `django.forms.Form._has_changed()` to `has_changed()` is removed.
- The `removetags` template filter is removed.
- The `remove_tags()` and `strip_entities()` functions in `django.utils.html` is removed.
- The `is_admin_site` argument to `django.contrib.auth.views.password_reset()` is removed.
- `django.db.models.field.subclassing.SubfieldBase` is removed.
- `django.utils.checksums` is removed.
- The `original_content_type_id` attribute on `django.contrib.admin.helpers.InlineAdminForm` is removed.
- The backwards compatibility shim to allow `FormMixin.get_form()` to be defined with no default value for its `form_class` argument is removed.
- The following settings are removed, and you must upgrade to the `TEMPLATES` setting:
 - `ALLOWED_INCLUDE_ROOTS`
 - `TEMPLATE_CONTEXT_PROCESSORS`
 - `TEMPLATE_DEBUG`
 - `TEMPLATE_DIRS`
 - `TEMPLATE_LOADERS`
 - `TEMPLATE_STRING_IF_INVALID`

- The backwards compatibility alias `django.template.loader.BaseLoader` is removed.
- Django template objects returned by `get_template()` and `select_template()` no longer accept a `Context` in their `render()` method.
- Template response APIs enforce the use of `dict` and backend-dependent template objects instead of `Context` and `Template` respectively.
- The `current_app` parameter for the following function and classes is removed:
 - `django.shortcuts.render()`
 - `django.template.Context()`
 - `django.template.RequestContext()`
 - `django.template.response.TemplateResponse()`
- The `dictionary` and `context_instance` parameters for the following functions are removed:
 - `django.shortcuts.render()`
 - `django.shortcuts.render_to_response()`
 - `django.template.loader.render_to_string()`
- The `dirs` parameter for the following functions is removed:
 - `django.template.loader.get_template()`
 - `django.template.loader.select_template()`
 - `django.shortcuts.render()`
 - `django.shortcuts.render_to_response()`
- Session verification is enabled regardless of whether or not `'django.contrib.auth.middleware.SessionAuthenticationMiddleware'` is in `MIDDLEWARE_CLASSES`. `SessionAuthenticationMiddleware` no longer has any purpose and can be removed from `MIDDLEWARE_CLASSES`. It's kept as a stub until Django 2.0 as a courtesy for users who don't read this note.
- Private attribute `django.db.models.Field.related` is removed.
- The `--list` option of the `migrate` management command is removed.
- The `ssi` template tag is removed.
- Support for the `=` comparison operator in the `if` template tag is removed.
- The backwards compatibility shims to allow `Storage.get_available_name()` and `Storage.save()` to be defined without a `max_length` argument are removed.
- Support for the legacy `%(<foo>)s` syntax in `ModelFormMixin.success_url` is removed.

- GeoQuerySet aggregate methods `collect()`, `extent()`, `extent3d()`, `make_line()`, and `unionagg()` are removed.
- The ability to specify `ContentType.name` when creating a content type instance is removed.
- Support for the old signature of `allow_migrate` is removed.
- Support for the syntax of `{% cycle %}` that uses comma-separated arguments is removed.
- The warning that *Signer* issued when given an invalid separator is now a `ValueError`.

9.1.12 1.9 release

Django 1.9.13 release notes

April 4, 2017

Django 1.9.13 fixes two security issues and a bug in 1.9.12. This is the final release of the 1.9.x series.

CVE-2017-7233: Open redirect and possible XSS attack via user-supplied numeric redirect URLs

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()` and [i18n](#)) to redirect the user to an “on success” URL. The security check for these redirects (namely `django.utils.http.is_safe_url()`) considered some numeric URLs (e.g. `http:999999999`) “safe” when they shouldn’t be.

Also, if a developer relies on `is_safe_url()` to provide safe redirect targets and puts such a URL into a link, they could suffer from an XSS attack.

CVE-2017-7234: Open redirect vulnerability in `django.views.static.serve()`

A maliciously crafted URL to a Django site using the `serve()` view could redirect to any other domain. The view no longer does any redirects as they don’t provide any known, useful functionality.

Note, however, that this view has always carried a warning that it is not hardened for production use and should be used only as a development aid.

Bugfixes

- Fixed a regression in the `timesince` and `timeuntil` filters that caused incorrect results for dates in a leap year ([#27637](#)).

Django 1.9.12 release notes

December 1, 2016

Django 1.9.12 fixes a regression in 1.9.11.

Bugfixes

- Quoted the Oracle test user’s password in queries to fix the “ORA-00922: missing or invalid option” error when the password starts with a number or special character ([#27420](#)).

Django 1.9.11 release notes

November 1, 2016

Django 1.9.11 fixes two security issues in 1.9.10.

User with hardcoded password created when running tests on Oracle

When running tests with an Oracle database, Django creates a temporary database user. In older versions, if a password isn’t manually specified in the database settings `TEST` dictionary, a hardcoded password is used. This could allow an attacker with network access to the database server to connect.

This user is usually dropped after the test suite completes, but not when using the `manage.py test --keepdb` option or if the user has an active session (such as an attacker’s connection).

A randomly generated password is now used for each test run.

DNS rebinding vulnerability when `DEBUG=True`

Older versions of Django don’t validate the `Host` header against `settings.ALLOWED_HOSTS` when `settings.DEBUG=True`. This makes them vulnerable to a [DNS rebinding attack](#).

While Django doesn’t ship a module that allows remote code execution, this is at least a cross-site scripting vector, which could be quite serious if developers load a copy of the production database in development or connect to some production services for which there’s no development instance, for example. If a project uses a package like the `django-debug-toolbar`, then the attacker could execute arbitrary SQL, which could be especially bad if the developers connect to the database with a superuser account.

`settings.ALLOWED_HOSTS` is now validated regardless of `DEBUG`. For convenience, if `ALLOWED_HOSTS` is empty and `DEBUG=True`, the following variations of `localhost` are allowed `['localhost', '127.0.0.1', '::1']`. If your local settings file has your production `ALLOWED_HOSTS` value, you must now omit it to get those fallback values.

Django 1.9.10 release notes

September 26, 2016

Django 1.9.10 fixes a security issue in 1.9.9.

CSRF protection bypass on a site with Google Analytics

An interaction between Google Analytics and Django’s cookie parsing could allow an attacker to set arbitrary cookies leading to a bypass of CSRF protection.

The parser for `request.COOKIES` is simplified to better match the behavior of browsers and to mitigate this attack. `request.COOKIES` may now contain cookies that are invalid according to [RFC 6265](#) but are possible to set via `document.cookie`.

Django 1.9.9 release notes

August 1, 2016

Django 1.9.9 fixes several bugs in 1.9.8.

Bugfixes

- Fixed invalid HTML in template postmortem on the debug page ([#26938](#)).
- Fixed some GIS database function crashes on MySQL 5.7 ([#26657](#)).

Django 1.9.8 release notes

July 18, 2016

Django 1.9.8 fixes a security issue and several bugs in 1.9.7.

XSS in admin’s add/change related popup

Unsafe usage of JavaScript’s `Element.innerHTML` could result in XSS in the admin’s add/change related popup. `Element.textContent` is now used to prevent execution of the data.

The debug view also used `innerHTML`. Although a security issue wasn’t identified there, out of an abundance of caution it’s also updated to use `textContent`.

Bugfixes

- Fixed missing `varchar/text_pattern_ops` index on `CharField` and `TextField` respectively when using `AddField` on PostgreSQL (#26889).
- Fixed `makemessages` crash on Python 2 with non-ASCII file names (#26897).

Django 1.9.7 release notes

June 4, 2016

Django 1.9.7 fixes several bugs in 1.9.6.

Bugfixes

- Removed the need for the `request` context processor on the admin login page to fix a regression in 1.9 (#26558).
- Fixed translation of password validators' `help_text` in forms (#26544).
- Fixed a regression causing the cached template loader to crash when using lazy template names (#26603).
- Fixed `on_commit` callbacks execution order when callbacks make transactions (#26627).
- Fixed `HStoreField` to raise a `ValidationError` instead of crashing on non-dictionary JSON input (#26672).
- Fixed `dbshell` crash on PostgreSQL with an empty database name (#26698).
- Fixed a regression in queries on a `OneToOneField` that has `to_field` and `primary_key=True` (#26667).

Django 1.9.6 release notes

May 2, 2016

Django 1.9.6 fixes several bugs in 1.9.5.

Bugfixes

- Added support for relative path redirects to the test client and to `SimpleTestCase.assertRedirects()` because Django 1.9 no longer converts redirects to absolute URIs (#26428).
- Fixed `TimeField` microseconds round-tripping on MySQL and SQLite (#26498).
- Prevented `makemigrations` from generating infinite migrations for a model field that references a `functools.partial` (#26475).

- Fixed a regression where `SessionBase.pop()` returned `None` rather than raising a `KeyError` for non-existent values (#26520).
- Fixed a regression causing the cached template loader to crash when using template names starting with a dash (#26536).
- Restored conversion of an empty string to null when saving values of `GenericIPAddressField` on SQLite and MySQL (#26557).
- Fixed a `makemessages` regression where temporary `.py` extensions were leaked in source file paths (#26341).

Django 1.9.5 release notes

April 1, 2016

Django 1.9.5 fixes several bugs in 1.9.4.

Bugfixes

- Made `MultiPartParser` ignore filenames that normalize to an empty string to fix crash in `MemoryFileUploadHandler` on specially crafted user input (#26325).
- Fixed a race condition in `BaseCache.get_or_set()` (#26332). It now returns the `default` value instead of `False` if there's an error when trying to add the value to the cache.
- Fixed data loss on SQLite where `DurationField` values with fractional seconds could be saved as `None` (#26324).
- The forms in `contrib.auth` no longer strip trailing and leading whitespace from the password fields (#26334). The change requires users who set their password to something with such whitespace after a site updated to Django 1.9 to reset their password. It provides backwards-compatibility for earlier versions of Django.
- Fixed a memory leak in the cached template loader (#26306).
- Fixed a regression that caused `collectstatic --clear` to fail if the storage doesn't implement `path()` (#26297).
- Fixed a crash when using a reverse lookup with a subquery when a `ForeignKey` has a `to_field` set to something other than the primary key (#26373).
- Fixed a regression in `CommonMiddleware` that caused spurious warnings in logs on requests missing a trailing slash (#26293).
- Restored the functionality of the admin's `raw_id_fields` in `list_editable` (#26387).
- Fixed a regression with abstract model inheritance and explicit parent links (#26413).

- Fixed a migrations crash on SQLite when renaming the primary key of a model containing a `ForeignKey` to `'self'` (#26384).
- Fixed `JSONField` inadvertently escaping its contents when displaying values after failed form validation (#25532).

Django 1.9.4 release notes

March 5, 2016

Django 1.9.4 fixes a regression on Python 2 in the 1.9.3 security release where `utils.http.is_safe_url()` crashes on bytestring URLs (#26308).

Django 1.9.3 release notes

March 1, 2016

Django 1.9.3 fixes two security issues and several bugs in 1.9.2.

CVE-2016-2512: Malicious redirect and possible XSS attack via user-supplied redirect URLs containing basic auth

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()` and [118n](#)) to redirect the user to an “on success” URL. The security check for these redirects (namely `django.utils.http.is_safe_url()`) considered some URLs with basic authentication credentials “safe” when they shouldn’t be.

For example, a URL like `http://mysite.example.com\@attacker.com` would be considered safe if the request’s host is `http://mysite.example.com`, but redirecting to this URL sends the user to `attacker.com`.

Also, if a developer relies on `is_safe_url()` to provide safe redirect targets and puts such a URL into a link, they could suffer from an XSS attack.

CVE-2016-2513: User enumeration through timing difference on password hasher work factor upgrade

In each major version of Django since 1.6, the default number of iterations for the `PBKDF2PasswordHasher` and its subclasses has increased. This improves the security of the password as the speed of hardware increases, however, it also creates a timing difference between a login request for a user with a password encoded in an older number of iterations and login request for a nonexistent user (which runs the default hasher’s default number of iterations since Django 1.6).

This only affects users who haven’t logged in since the iterations were increased. The first time a user logs in after an iterations increase, their password is updated with the new iterations and there is no longer a timing difference.

The new `BasePasswordHasher.harden_runtime()` method allows hashers to bridge the runtime gap between the work factor (e.g. iterations) supplied in existing encoded passwords and the default work factor of the hasher. This method is implemented for `PBKDF2PasswordHasher` and `BCryptPasswordHasher`. The number of rounds for the latter hasher hasn't changed since Django 1.4, but some projects may subclass it and increase the work factor as needed.

A warning will be emitted for any [third-party password hashers that don't implement a `harden\_runtime\(\)` method](#).

If you have different password hashes in your database (such as SHA1 hashes from users who haven't logged in since the default hasher switched to PBKDF2 in Django 1.4), the timing difference on a login request for these users may be even greater and this fix doesn't remedy that difference (or any difference when changing hashers). You may be able to [upgrade those hashes](#) to prevent a timing attack for that case.

Bugfixes

- Skipped URL checks (new in 1.9) if the `ROOT_URLCONF` setting isn't defined ([#26155](#)).
- Fixed a crash on PostgreSQL that prevented using `TIME_ZONE=None` and `USE_TZ=False` ([#26177](#)).
- Added system checks for query name clashes of hidden relationships ([#26162](#)).
- Fixed a regression for cases where `ForeignKey.get_extra_descriptor_filter()` returned a `Q` object ([#26153](#)).
- Fixed regression with an `__in=qs` lookup for a `ForeignKey` with `to_field` set ([#26196](#)).
- Made `forms.FileField` and `utils.translation.lazy_number()` picklable ([#26212](#)).
- Fixed `RangeField` and `ArrayField` serialization with `None` values ([#26215](#)).
- Fixed a crash when filtering by a `Decimal` in `RawQuery` ([#26219](#)).
- Reallowed dashes in top-level domain names of URLs checked by `URLValidator` to fix a regression in Django 1.8 ([#26204](#)).
- Fixed some crashing deprecation shims in `SimpleTemplateResponse` that regressed in Django 1.9 ([#26253](#)).
- Fixed `BoundField` to reallow slices of subwidgets ([#26267](#)).
- Changed the admin's "permission denied" message in the login template to use `get_username` instead of `username` to support custom user models ([#26231](#)).
- Fixed a crash when passing a nonexistent template name to the cached template loader's `load_template()` method ([#26280](#)).
- Prevented `ContentTypeManager` instances from sharing their cache ([#26286](#)).
- Reverted a change in Django 1.9.2 ([#25858](#)) that prevented relative lazy relationships defined on abstract models to be resolved according to their concrete model's `app_label` ([#26186](#)).

Django 1.9.2 release notes

February 1, 2016

Django 1.9.2 fixes a security regression in 1.9 and several bugs in 1.9.1. It also makes a small backwards incompatible change that hopefully doesn't affect any users.

Security issue: User with “change” but not “add” permission can create objects for `ModelAdmin`'s with `save_as=True`

If a `ModelAdmin` uses `save_as=True` (not the default), the admin provides an option when editing objects to “Save as new”. A regression in Django 1.9 prevented that form submission from raising a “Permission Denied” error for users without the “add” permission.

Backwards incompatible change: `.py-tpl` files rewritten in project/app templates

The addition of some Django template language syntax to the default app template in Django 1.9 means those files now have some invalid Python syntax. This causes difficulties for packaging systems that unconditionally byte-compile `*.py` files.

To remedy this, a `.py-tpl` suffix is now used for the project and app template files included in Django. The `.py-tpl` suffix is replaced with `.py` by the `startproject` and `startapp` commands. For example, a template with the filename `manage.py-tpl` will be created as `manage.py`.

Please file a ticket if you have a custom project template containing `.py-tpl` files and find this behavior problematic.

Bugfixes

- Fixed a regression in `ConditionalGetMiddleware` causing `If-None-Match` checks to always return HTTP 200 (#26024).
- Fixed a regression that caused the “user-tools” items to display on the admin's logout page (#26035).
- Fixed a crash in the translations system when the current language has no translations (#26046).
- Fixed a regression that caused the incorrect day to be selected when opening the admin calendar widget for timezones from GMT+0100 to GMT+1200 (#24980).
- Fixed a regression in the admin's edit related model popup that caused an escaped value to be displayed in the select dropdown of the parent window (#25997).
- Fixed a regression in 1.8.8 causing incorrect index handling in migrations on PostgreSQL when adding `db_index=True` or `unique=True` to a `CharField` or `TextField` that already had the other specified, or when removing one of them from a field that had both, or when adding `unique=True` to a field already listed in `unique_together` (#26034).

- Fixed a regression where defining a relation on an abstract model's field using a string model name without an `app_label` no longer resolved that reference to the abstract model's app if using that model in another application (#25858).
- Fixed a crash when destroying an existing test database on MySQL or PostgreSQL (#26096).
- Fixed CSRF cookie check on POST requests when `USE_X_FORWARDED_PORT=True` (#26094).
- Fixed a `QuerySet.order_by()` crash when ordering by a relational field of a `ManyToManyField` through model (#26092).
- Fixed a regression that caused an exception when making database queries on SQLite with more than 2000 parameters when `DEBUG` is `True` on distributions that increase the `SQLITE_MAX_VARIABLE_NUMBER` compile-time limit to over 2000, such as Debian (#26063).
- Fixed a crash when using a reverse `OneToOneField` in `ModelAdmin.readonly_fields` (#26060).
- Fixed a crash when calling the `migrate` command in a test case with the `available_apps` attribute pointing to an application with migrations disabled using the `MIGRATION_MODULES` setting (#26135).
- Restored the ability for testing and debugging tools to determine the template from which a node came from, even during template inheritance or inclusion. Prior to Django 1.9, debugging tools could access the template origin from the node via `Node.token.source[0]`. This was an undocumented, private API. The origin is now available directly on each node using the `Node.origin` attribute (#25848).
- Fixed a regression in Django 1.8.5 that broke copying a `SimpleLazyObject` with `copy.copy()` (#26122).
- Always included `geometry_field` in the GeoJSON serializer output regardless of the `fields` parameter (#26138).
- Fixed the `contrib.gis` map widgets when using `USE_THOUSAND_SEPARATOR=True` (#20415).
- Made invalid forms display the initial of values of their disabled fields (#26129).

Django 1.9.1 release notes

January 2, 2016

Django 1.9.1 fixes several bugs in 1.9.

Bugfixes

- Fixed `BaseCache.get_or_set()` with the `DummyCache` backend (#25840).
- Fixed a regression in `FormMixin` causing forms to be validated twice (#25548, #26018).
- Fixed a system check crash with nested `ArrayFields` (#25867).
- Fixed a state bug when migrating a `SeparateDatabaseAndState` operation backwards (#25896).

- Fixed a regression in `CommonMiddleware` causing `If-None-Match` checks to always return HTTP 200 (#25900).
- Fixed missing `varchar/text_pattern_ops` index on `CharField` and `TextField` respectively when using `AlterField` on PostgreSQL (#25412).
- Fixed admin's delete confirmation page's summary counts of related objects (#25883).
- Added `from __future__ import unicode_literals` to the default `apps.py` created by `startapp` on Python 2 (#25909). Add this line to your own `apps.py` files created using Django 1.9 if you want your migrations to work on both Python 2 and Python 3.
- Prevented `QuerySet.delete()` from crashing on MySQL when querying across relations (#25882).
- Fixed evaluation of zero-length slices of `QuerySet.values()` (#25894).
- Fixed a state bug when using an `AlterModelManagers` operation (#25852).
- Fixed `TypedChoiceField` change detection with nullable fields (#25942).
- Fixed incorrect timezone warnings in custom admin templates that don't have a `data-admin-utc-offset` attribute in the body tag. (#25845).
- Fixed a regression which prevented using a language not in Django's default language list (*[LANGUAGES](#)*) (#25915).
- Avoided hiding some exceptions, like an invalid `INSTALLED_APPS` setting, behind `AppRegistryNotReady` when starting `runserver` (#25510). This regression appeared in 1.8.5 as a side effect of fixing #24704 and by mistake the fix wasn't applied to the `stable/1.9.x` branch.
- Fixed `migrate --fake-initial` detection of many-to-many tables (#25922).
- Restored the functionality of the admin's `list_editable` add and change buttons (#25903).
- Fixed `isnull` query lookup for `ForeignKey` (#25972).
- Fixed a regression in the admin which ignored line breaks in read-only fields instead of converting them to `<br>` (#25465).
- Fixed incorrect object reference in `SingleObjectMixin.get_context_object_name()` (#26006).
- Made `loaddata` skip disabling and enabling database constraints when it doesn't load any fixtures (#23372).
- Restored `contrib.auth` hashers compatibility with `py-bcrypt` (#26016).
- Fixed a crash in `QuerySet.values()/values_list()` after an `annotate()` and `order_by()` when `values()/values_list()` includes a field not in the `order_by()` (#25316).

Django 1.9 release notes

December 1, 2015

Welcome to Django 1.9!

These release notes cover the [new features](#), as well as some [backwards incompatible changes](#) you'll want to be aware of when upgrading from Django 1.8 or older versions. We've [dropped some features](#) that have reached the end of their deprecation cycle, and we've [begun the deprecation process](#) for some features.

See the [How to upgrade Django to a newer version](#) guide if you're updating an existing project.

Python compatibility

Django 1.9 requires Python 2.7, 3.4, or 3.5. We highly recommend and only officially support the latest release of each series.

The Django 1.8 series is the last to support Python 3.2 and 3.3.

What's new in Django 1.9

Performing actions after a transaction commit

The new `on_commit()` hook allows performing actions after a database transaction is successfully committed. This is useful for tasks such as sending notification emails, creating queued tasks, or invalidating caches.

This functionality from the [django-transaction-hooks](#) package has been integrated into Django.

Password validation

Django now offers password validation to help prevent the usage of weak passwords by users. The validation is integrated in the included password change and reset forms and is simple to integrate in any other code. Validation is performed by one or more validators, configured in the new `AUTH_PASSWORD_VALIDATORS` setting.

Four validators are included in Django, which can enforce a minimum length, compare the password to the user's attributes like their name, ensure passwords aren't entirely numeric, or check against an included list of common passwords. You can combine multiple validators, and some validators have custom configuration options. For example, you can choose to provide a custom list of common passwords. Each validator provides a help text to explain its requirements to the user.

By default, no validation is performed and all passwords are accepted, so if you don't set `AUTH_PASSWORD_VALIDATORS`, you will not see any change. In new projects created with the default `startproject` template, a simple set of validators is enabled. To enable basic validation in the included auth forms for your project, you could set, for example:

```
AUTH_PASSWORD_VALIDATORS = [
    {
        "NAME": "django.contrib.auth.password_validation.UserAttributeSimilarityValidator",
    },
    {
        "NAME": "django.contrib.auth.password_validation.MinimumLengthValidator",
    },
    {
        "NAME": "django.contrib.auth.password_validation.CommonPasswordValidator",
    },
    {
        "NAME": "django.contrib.auth.password_validation.NumericPasswordValidator",
    },
]
```

See [Password validation](#) for more details.

Permission mixins for class-based views

Django now ships with the mixins *AccessMixin*, *LoginRequiredMixin*, *PermissionRequiredMixin*, and *UserPassesTestMixin* to provide the functionality of the `django.contrib.auth.decorators` for class-based views. These mixins have been taken from, or are at least inspired by, the [django-braces](#) project.

There are a few differences between Django's and `django-braces`' implementation, though:

- The *raise_exception* attribute can only be `True` or `False`. Custom exceptions or callables are not supported.
- The *handle_no_permission()* method does not take a `request` argument. The current request is available in `self.request`.
- The custom *test_func()* of *UserPassesTestMixin* does not take a `user` argument. The current user is available in `self.request.user`.
- The *permission_required* attribute supports a string (defining one permission) or a list/tuple of strings (defining multiple permissions) that need to be fulfilled to grant access.
- The new *permission_denied_message* attribute allows passing a message to the `PermissionDenied` exception.

New styling for `contrib.admin`

The admin sports a modern, flat design with new SVG icons which look perfect on HiDPI screens. It still provides a fully-functional experience to YUI's A-grade browsers. Older browser may experience varying levels of graceful degradation.

Running tests in parallel

The `test` command now supports a `--parallel` option to run a project's tests in multiple processes in parallel.

Each process gets its own database. You must ensure that different test cases don't access the same resources. For instance, test cases that touch the filesystem should create a temporary directory for their own use.

This option is enabled by default for Django's own test suite provided:

- the OS supports it (all but Windows)
- the database backend supports it (all the built-in backends but Oracle)

Minor features

`django.contrib.admin`

- Admin views now have `model_admin` or `admin_site` attributes.
- The URL of the admin change view has been changed (was at `/admin/<app>/<model>/<pk>/` by default and is now at `/admin/<app>/<model>/<pk>/change/`). This should not affect your application unless you have hardcoded admin URLs. In that case, replace those links by [reversing admin URLs](#) instead. Note that the old URL still redirects to the new one for backwards compatibility, but it may be removed in a future version.
- `ModelAdmin.get_list_select_related()` was added to allow changing the `select_related()` values used in the admin's changelist query based on the request.
- The `available_apps` context variable, which lists the available applications for the current user, has been added to the `AdminSite.each_context()` method.
- `AdminSite.empty_value_display` and `ModelAdmin.empty_value_display` were added to override the display of empty values in admin change list. You can also customize the value for each field.
- Added jQuery events [when an inline form is added or removed](#) on the change form page.
- The time picker widget includes a '6 p.m' option for consistency of having predefined options every 6 hours.
- JavaScript slug generation now supports Romanian characters.

`django.contrib.admindocs`

- The model section of the `admindocs` now also describes methods that take arguments, rather than ignoring them.

`django.contrib.auth`

- The default iteration count for the PBKDF2 password hasher has been increased by 20%. This backwards compatible change will not affect users who have subclassed `django.contrib.auth.hashers.PBKDF2PasswordHasher` to change the default value.
- The `BCryptSHA256PasswordHasher` will now update passwords if its `rounds` attribute is changed.
- `AbstractBaseUser` and `BaseUserManager` were moved to a new `django.contrib.auth.base_user` module so that they can be imported without including `django.contrib.auth` in `INSTALLED_APPS` (doing so raised a deprecation warning in older versions and is no longer supported in Django 1.9).
- The permission argument of `permission_required()` accepts all kinds of iterables, not only list and tuples.
- The new `PersistentRemoteUserMiddleware` makes it possible to use `REMOTE_USER` for setups where the header is only populated on login pages instead of every request in the session.
- The `django.contrib.auth.views.password_reset()` view accepts an `extra_email_context` parameter.

`django.contrib.contenttypes`

- It's now possible to use `order_with_respect_to` with a `GenericForeignKey`.

`django.contrib.gis`

- All `GeoQuerySet` methods have been deprecated and replaced by [equivalent database functions](#). As soon as the legacy methods have been replaced in your code, you should even be able to remove the special `GeoManager` from your GIS-enabled classes.
- The GDAL interface now supports instantiating file-based and in-memory `GDALRaster` objects from raw data. Setters for raster properties such as projection or pixel values have been added.
- For PostGIS users, the new `RasterField` allows [storing GDALRaster objects](#). It supports automatic spatial index creation and reprojection when saving a model. It does not yet support spatial querying.
- The new `GDALRaster.warp()` method allows warping a raster by specifying target raster properties such as origin, width, height, or pixel size (among others).

- The new `GDALRaster.transform()` method allows transforming a raster into a different spatial reference system by specifying a target `srid`.
- The new `GeoIP2` class allows using MaxMind's GeoLite2 databases which includes support for IPv6 addresses.
- The default OpenLayers library version included in widgets has been updated from 2.13 to 2.13.1.

`django.contrib.postgres`

- Added support for the `rangefield.contained_by` lookup for some built in fields which correspond to the range fields.
- Added `django.contrib.postgres.fields.JSONField`.
- Added PostgreSQL specific aggregation functions.
- Added the `TransactionNow` database function.

`django.contrib.sessions`

- The session model and `SessionStore` classes for the `db` and `cached_db` backends are refactored to allow a custom database session backend to build upon them. See [Extending database-backed session engines](#) for more details.

`django.contrib.sites`

- `get_current_site()` now handles the case where `request.get_host()` returns `domain:port`, e.g. `example.com:80`. If the lookup fails because the host does not match a record in the database and the host has a port, the port is stripped and the lookup is retried with the domain part only.

`django.contrib.syndication`

- Support for multiple enclosures per feed item has been added. If multiple enclosures are defined on a RSS feed, an exception is raised as RSS feeds, unlike Atom feeds, do not support multiple enclosures per feed item.

Cache

- `django.core.cache.backends.base.BaseCache` now has a `get_or_set()` method.
- `django.views.decorators.cache.never_cache()` now sends more persuasive headers (added `no-cache`, `no-store`, `must-revalidate` to `Cache-Control`) to better prevent caching. This was also added in Django 1.8.8.

CSRF

- The request header's name used for CSRF authentication can be customized with `CSRF_HEADER_NAME`.
- The CSRF referer header is now validated against the `CSRF_COOKIE_DOMAIN` setting if set. See [How it works](#) for details.
- The new `CSRF_TRUSTED_ORIGINS` setting provides a way to allow cross-origin unsafe requests (e.g. POST) over HTTPS.

Database backends

- The PostgreSQL backend (`django.db.backends.postgresql_psycopg2`) is also available as `django.db.backends.postgresql`. The old name will continue to be available for backwards compatibility.

File Storage

- `Storage.get_valid_name()` is now called when the `upload_to` is a callable.
- `File` now has the `seekable()` method when using Python 3.

Forms

- `ModelForm` accepts the new Meta option `field_classes` to customize the type of the fields. See [Overriding the default fields](#) for details.
- You can now specify the order in which form fields are rendered with the `field_order` attribute, the `field_order` constructor argument, or the `order_fields()` method.
- A form prefix can be specified inside a form class, not only when instantiating a form. See [Prefixes for forms](#) for details.
- You can now specify keyword arguments that you want to pass to the constructor of forms in a formset.
- `SlugField` now accepts an `allow_unicode` argument to allow Unicode characters in slugs.
- `CharField` now accepts a `strip` argument to strip input data of leading and trailing whitespace. As this defaults to `True` this is different behavior from previous releases.

- Form fields now support the *disabled* argument, allowing the field widget to be displayed disabled by browsers.
- It's now possible to customize bound fields by overriding a field's *get_bound_field()* method.

Generic Views

- Class-based views generated using *as_view()* now have *view_class* and *view_initkwargs* attributes.
- *method_decorator()* can now be used with a list or tuple of decorators. It can also be used to *decorate* classes instead of methods.

Internationalization

- The *django.views.i18n.set_language()* view now properly redirects to *translated URLs*, when available.
- The *django.views.i18n.javascript_catalog()* view now works correctly if used multiple times with different configurations on the same page.
- The *django.utils.timezone.make_aware()* function gained an *is_dst* argument to help resolve ambiguous times during DST transitions.
- You can now use locale variants supported by gettext. These are usually used for languages which can be written in different scripts, for example Latin and Cyrillic (e.g. *be@latin*).
- Added the *django.views.i18n.json_catalog()* view to help build a custom client-side i18n library upon Django translations. It returns a JSON object containing a translations catalog, formatting settings, and a plural rule.
- Added the *name_translated* attribute to the object returned by the *get_language_info* template tag. Also added a corresponding template filter: *language_name_translated*.
- You can now run *compilemessages* from the root directory of your project and it will find all the app message files that were created by *makemessages*.
- *makemessages* now calls *xgettext* once per locale directory rather than once per translatable file. This speeds up localization builds.
- *blocktrans* supports assigning its output to a variable using *asvar*.
- Two new languages are available: Colombian Spanish and Scottish Gaelic.

Management Commands

- The new `sendtestemail` command lets you send a test email to easily confirm that email sending through Django is working.
- To increase the readability of the SQL code generated by `sqlmigrate`, the SQL code generated for each migration operation is preceded by the operation's description.
- The `dumpdata` command output is now deterministically ordered. Moreover, when the `--output` option is specified, it also shows a progress bar in the terminal.
- The `createcachetable` command now has a `--dry-run` flag to print out the SQL rather than execute it.
- The `startapp` command creates an `apps.py` file. Since it doesn't use `default_app_config` (a discouraged API), you must specify the app config's path, e.g. `'polls.apps.PollsConfig'`, in `INSTALLED_APPS` for it to be used (instead of just `'polls'`).
- When using the PostgreSQL backend, the `dbshell` command can connect to the database using the password from your settings file (instead of requiring it to be manually entered).
- The `django` package may be run as a script, i.e. `python -m django`, which will behave the same as `django-admin`.
- Management commands that have the `--noinput` option now also take `--no-input` as an alias for that option.

Migrations

- Initial migrations are now marked with an `initial = True` class attribute which allows `migrate --fake-initial` to more easily detect initial migrations.
- Added support for serialization of `functools.partial` and `LazyObject` instances.
- When supplying `None` as a value in `MIGRATION_MODULES`, Django will consider the app an app without migrations.
- When applying migrations, the “Rendering model states” step that's displayed when running `migrate` with verbosity 2 or higher now computes only the states for the migrations that have already been applied. The model states for migrations being applied are generated on demand, drastically reducing the amount of required memory.

However, this improvement is not available when unapplying migrations and therefore still requires the precomputation and storage of the intermediate migration states.

This improvement also requires that Django no longer supports mixed migration plans. Mixed plans consist of a list of migrations where some are being applied and others are being unapplied. This was never officially supported and never had a public API that supports this behavior.

- The `squashmigrations` command now supports specifying the starting migration from which migrations will be squashed.

Models

- `QuerySet.bulk_create()` now works on proxy models.
- Database configuration gained a `TIME_ZONE` option for interacting with databases that store datetimes in local time and don't support time zones when `USE_TZ` is `True`.
- Added the `RelatedManager.set()` method to the related managers created by `ForeignKey`, `GenericForeignKey`, and `ManyToManyField`.
- The `add()` method on a reverse foreign key now has a `bulk` parameter to allow executing one query regardless of the number of objects being added rather than one query per object.
- Added the `keep_parents` parameter to `Model.delete()` to allow deleting only a child's data in a model that uses multi-table inheritance.
- `Model.delete()` and `QuerySet.delete()` return the number of objects deleted.
- Added a system check to prevent defining both `Meta.ordering` and `order_with_respect_to` on the same model.
- `Date` and `time` lookups can be chained with other lookups (such as `exact`, `gt`, `lt`, etc.). For example: `Entry.objects.filter(pub_date__month__gt=6)`.
- Time lookups (hour, minute, second) are now supported by `TimeField` for all database backends. Support for backends other than SQLite was added but undocumented in Django 1.7.
- You can specify the `output_field` parameter of the `Avg` aggregate in order to aggregate over non-numeric columns, such as `DurationField`.
- Added the `date` lookup to `DateTimeField` to allow querying the field by only the date portion.
- Added the `Greatest` and `Least` database functions.
