- Added the `Now` database function, which returns the current date and time.
- `Transform` is now a subclass of `Func()` which allows `Transforms` to be used on the right hand side of an expression, just like regular `Funcs`. This allows registering some database functions like `Length`, `Lower`, and `Upper` as transforms.
- `SlugField` now accepts an `allow_unicode` argument to allow Unicode characters in slugs.
- Added support for referencing annotations in `QuerySet.distinct()`.
- `connection.queries` shows queries with substituted parameters on SQLite.
- `Query expressions` can now be used when creating new model instances using `save()`, `create()`, and `bulk_create()`.

Requests and Responses

- Unless `HttpResponse.reason_phrase` is explicitly set, it now is determined by the current value of `HttpResponse.status_code`. Modifying the value of `status_code` outside of the constructor will also modify the value of `reason_phrase`.
- The debug view now shows details of chained exceptions on Python 3.
- The default 40x error views now accept a second positional parameter, the exception that triggered the view.
- View error handlers now support `TemplateResponse`, commonly used with class-based views.
- Exceptions raised by the `render()` method are now passed to the `process_exception()` method of each middleware.
- Request middleware can now set `HttpRequest.urlconf` to `None` to revert any changes made by previous middleware and return to using the `ROOT_URLCONF`.
- The `DISALLOWED_USER_AGENTS` check in `CommonMiddleware` now raises a `PermissionDenied` exception as opposed to returning an `HttpResponseForbidden` so that `handler403` is invoked.
- Added `HttpRequest.get_port()` to fetch the originating port of the request.
- Added the `json_dumps_params` parameter to `JsonResponse` to allow passing keyword arguments to the `json.dumps()` call used to generate the response.
- The `BrokenLinkEmailsMiddleware` now ignores 404s when the referer is equal to the requested URL. To circumvent the empty referer check already implemented, some web bots set the referer to the requested URL.

Templates

- Template tags created with the `simple_tag()` helper can now store results in a template variable by using the `as` argument.
- Added a `Context.setdefault()` method.
- The `django.template` logger was added and includes the following messages:
 - A `DEBUG` level message for missing context variables.
 - A `WARNING` level message for uncaught exceptions raised during the rendering of an `{% include %}` when debug mode is off (helpful since `{% include %}` silences the exception and returns an empty string).
- The `firstof` template tag supports storing the output in a variable using `'as'`.
- `Context.update()` can now be used as a context manager.
- Django template loaders can now extend templates recursively.

- The debug page template `postmortem` now include output from each engine that is installed.
- [Debug page integration](#) for custom template engines was added.
- The `DjangoTemplates` backend gained the ability to register libraries and builtins explicitly through the template `OPTIONS`.
- The `timesince` and `timeuntil` filters were improved to deal with leap years when given large time spans.
- The `include` tag now caches parsed templates objects during template rendering, speeding up reuse in places such as for loops.

Tests

- Added the `json()` method to test client responses to give access to the response body as JSON.
- Added the `force_login()` method to the test client. Use this method to simulate the effect of a user logging into the site while skipping the authentication and verification steps of `login()`.

URLs

- Regular expression lookahead assertions are now allowed in URL patterns.
- The application namespace can now be set using an `app_name` attribute on the included module or object. It can also be set by passing a 2-tuple of (<list of patterns>, <application namespace>) as the first argument to `include()`.
- System checks have been added for common URL pattern mistakes.

Validators

- Added `django.core.validators.int_list_validator()` to generate validators of strings containing integers separated with a custom character.
- `EmailValidator` now limits the length of domain name labels to 63 characters per [RFC 1034](#).
- Added `validate_unicode_slug()` to validate slugs that may contain Unicode characters.

Backwards incompatible changes in 1.9

Warning: In addition to the changes outlined in this section, be sure to review the [Features removed in 1.9](#) for the features that have reached the end of their deprecation cycle and therefore been removed. If you haven't updated your code within the deprecation timeline for a given feature, its removal may appear as a backwards incompatible change.

Database backend API

- A couple of new tests rely on the ability of the backend to introspect column defaults (returning the result as `Field.default`). You can set the `can_introspect_default` database feature to `False` if your backend doesn't implement this. You may want to review the implementation on the backends that Django includes for reference ([#24245](#)).
- Registering a global adapter or converter at the level of the DB-API module to handle time zone information of `datetime` values passed as query parameters or returned as query results on databases that don't support time zones is discouraged. It can conflict with other libraries.

The recommended way to add a time zone to `datetime` values fetched from the database is to register a converter for `DateTimeField` in `DatabaseOperations.get_db_converters()`.

The `needs_datetime_string_cast` database feature was removed. Database backends that set it must register a converter instead, as explained above.

- The `DatabaseOperations.value_to_db_<type>()` methods were renamed to `adapt_<type>field_value()` to mirror the `convert_<type>field_value()` methods.
- To use the new date lookup, third-party database backends may need to implement the `DatabaseOperations.datetime_cast_date_sql()` method.
- The `DatabaseOperations.time_extract_sql()` method was added. It calls the existing `date_extract_sql()` method. This method is overridden by the SQLite backend to add time lookups (hour, minute, second) to *TimeField*, and may be needed by third-party database backends.
- The `DatabaseOperations.datetime_cast_sql()` method (not to be confused with `DatabaseOperations.datetime_cast_date_sql()` mentioned above) has been removed. This method served to format dates on Oracle long before 1.0, but hasn't been overridden by any core backend in years and hasn't been called anywhere in Django's code or tests.
- In order to support test parallelization, you must implement the `DatabaseCreation._clone_test_db()` method and set `DatabaseFeatures.can_clone_databases = True`. You may have to adjust `DatabaseCreation.get_test_db_clone_settings()`.

Default settings that were tuples are now lists

The default settings in `django.conf.global_settings` were a combination of lists and tuples. All settings that were formerly tuples are now lists.

`is_usable` attribute on template loaders is removed

Django template loaders previously required an `is_usable` attribute to be defined. If a loader was configured in the template settings and this attribute was `False`, the loader would be silently ignored. In practice, this was only used by the egg loader to detect if `setuptools` was installed. The `is_usable` attribute is now removed and the egg loader instead fails at runtime if `setuptools` is not installed.

Related set direct assignment

Direct assignment of related objects in the ORM used to perform a `clear()` followed by a call to `add()`. This caused needlessly large data changes and prevented using the `m2m_changed` signal to track individual changes in many-to-many relations.

Direct assignment now relies on the new `set()` method on related managers which by default only processes changes between the existing related set and the one that's newly assigned. The previous behavior can be restored by replacing direct assignment by a call to `set()` with the keyword argument `clear=True`.

`ModelForm`, and therefore `ModelAdmin`, internally rely on direct assignment for many-to-many relations and as a consequence now use the new behavior.

Filesystem-based template loaders catch more specific exceptions

When using the `filesystem.Loader` or `app_directories.Loader` template loaders, earlier versions of Django raised a `TemplateDoesNotExist` error if a template source existed but was unreadable. This could happen under many circumstances, such as if Django didn't have permissions to open the file, or if the template source was a directory. Now, Django only silences the exception if the template source does not exist. All other situations result in the original `IOError` being raised.

HTTP redirects no longer forced to absolute URIs

Relative redirects are no longer converted to absolute URIs. [RFC 2616](#) required the `Location` header in redirect responses to be an absolute URI, but it has been superseded by [RFC 7231](#) which allows relative URIs in `Location`, recognizing the actual practice of user agents, almost all of which support them.

Consequently, the expected URLs passed to `assertRedirects` should generally no longer include the scheme and domain part of the URLs. For example, `self.assertRedirects(response, 'http://testserver/`

`some-url/')` should be replaced by `self.assertRedirects(response, '/some-url/')` (unless the redirection specifically contained an absolute URL).

In the rare case that you need the old behavior (discovered with an ancient version of Apache with `mod_scgi` that interprets a relative redirect as an “internal redirect”), you can restore it by writing a custom middleware:

```
class LocationHeaderFix(object):
    def process_response(self, request, response):
        if "Location" in response:
            response["Location"] = request.build_absolute_uri(response["Location"])
        return response
```

Dropped support for PostgreSQL 9.0

Upstream support for PostgreSQL 9.0 ended in September 2015. As a consequence, Django 1.9 sets 9.1 as the minimum PostgreSQL version it officially supports.

Dropped support for Oracle 11.1

Upstream support for Oracle 11.1 ended in August 2015. As a consequence, Django 1.9 sets 11.2 as the minimum Oracle version it officially supports.

Bulk behavior of `add()` method of related managers

To improve performance, the `add()` methods of the related managers created by `ForeignKey` and `GenericForeignKey` changed from a series of `Model.save()` calls to a single `QuerySet.update()` call. The change means that `pre_save` and `post_save` signals aren't sent anymore. You can use the `bulk=False` keyword argument to revert to the previous behavior.

Template `LoaderOrigin` and `StringOrigin` are removed

In previous versions of Django, when a template engine was initialized with `debug` as `True`, an instance of `django.template.loader.LoaderOrigin` or `django.template.base.StringOrigin` was set as the `origin` attribute on the template object. These classes have been combined into `Origin` and is now always set regardless of the engine `debug` setting. For a minimal level of backwards compatibility, the old class names will be kept as aliases to the new `Origin` class until Django 2.0.

Changes to the default logging configuration

To make it easier to write custom logging configurations, Django's default logging configuration no longer defines `django.request` and `django.security` loggers. Instead, it defines a single `django` logger, filtered at the `INFO` level, with two handlers:

- `console`: filtered at the `INFO` level and only active if `DEBUG=True`.
- `mail_admins`: filtered at the `ERROR` level and only active if `DEBUG=False`.

If you aren't overriding Django's default logging, you should see minimal changes in behavior, but you might see some new logging to the `runserver` console, for example.

If you are overriding Django's default logging, you should check to see how your configuration merges with the new defaults.

HttpRequest details in error reporting

It was redundant to display the full details of the `HttpRequest` each time it appeared as a stack frame variable in the HTML version of the debug page and error email. Thus, the HTTP request will now display the same standard representation as other variables (`repr(request)`). As a result, the `ExceptionReporterFilter.get_request_repr()` method and the undocumented `django.http.build_request_repr()` function were removed.

The contents of the text version of the email were modified to provide a traceback of the same structure as in the case of AJAX requests. The traceback details are rendered by the `ExceptionReporter.get_traceback_text()` method.

Removal of time zone aware global adapters and converters for datetimes

Django no longer registers global adapters and converters for managing time zone information on `datetime` values sent to the database as query parameters or read from the database in query results. This change affects projects that meet all the following conditions:

- The `USE_TZ` setting is `True`.
- The database is SQLite, MySQL, Oracle, or a third-party database that doesn't support time zones. In doubt, you can check the value of `connection.features.supports_timezones`.
- The code queries the database outside of the ORM, typically with `cursor.execute(sql, params)`.

If you're passing aware `datetime` parameters to such queries, you should turn them into naive datetimes in UTC:

```
from django.utils import timezone

param = timezone.make_naive(param, timezone.utc)
```

If you fail to do so, the conversion will be performed as in earlier versions (with a deprecation warning) up until Django 1.11. Django 2.0 won't perform any conversion, which may result in data corruption.

If you're reading `datetime` values from the results, they will be naive instead of aware. You can compensate as follows:

```
from django.utils import timezone

value = timezone.make_aware(value, timezone.utc)
```

You don't need any of this if you're querying the database through the ORM, even if you're using `raw()` queries. The ORM takes care of managing time zone information.

Template tag modules are imported when templates are configured

The *DjangoTemplates* backend now performs discovery on installed template tag modules when instantiated. This update enables libraries to be provided explicitly via the 'libraries' key of *OPTIONS* when defining a *DjangoTemplates* backend. Import or syntax errors in template tag modules now fail early at instantiation time rather than when a template with a `{% load %}` tag is first compiled.

`django.template.base.add_to_builtins()` is removed

Although it was a private API, projects commonly used `add_to_builtins()` to make template tags and filters available without using the `{% load %}` tag. This API has been formalized. Projects should now define built-in libraries via the 'builtins' key of *OPTIONS* when defining a *DjangoTemplates* backend.

`simple_tag` now wraps tag output in `conditional_escape`

In general, template tags do not autoescape their contents, and this behavior is [documented](#). For tags like *inclusion_tag*, this is not a problem because the included template will perform autoescaping. For `assignment_tag()`, the output will be escaped when it is used as a variable in the template.

For the intended use cases of *simple_tag*, however, it is very easy to end up with incorrect HTML and possibly an XSS exploit. For example:

```
@register.simple_tag(takes_context=True)
def greeting(context):
    return "Hello {0}!".format(context["request"].user.first_name)
```

In older versions of Django, this will be an XSS issue because `user.first_name` is not escaped.

In Django 1.9, this is fixed: if the template context has `autoescape=True` set (the default), then `simple_tag` will wrap the output of the tag function with `conditional_escape()`.

To fix your `simple_tags`, it is best to apply the following practices:

- Any code that generates HTML should use either the template system or `format_html()`.
- If the output of a `simple_tag` needs escaping, use `escape()` or `conditional_escape()`.
- If you are absolutely certain that you are outputting HTML from a trusted source (e.g. a CMS field that stores HTML entered by admins), you can mark it as such using `mark_safe()`.

Tags that follow these rules will be correct and safe whether they are run on Django 1.9+ or earlier.

`Paginator.page_range`

`Paginator.page_range` is now an iterator instead of a list.

In versions of Django previous to 1.8, `Paginator.page_range` returned a `list` in Python 2 and a `range` in Python 3. Django 1.8 consistently returned a list, but an iterator is more efficient.

Existing code that depends on `list` specific features, such as indexing, can be ported by converting the iterator into a `list` using `list()`.

Implicit `QuerySet __in` lookup removed

In earlier versions, queries such as:

```
Model.objects.filter(related_id=RelatedModel.objects.all())
```

would implicitly convert to:

```
Model.objects.filter(related_id__in=RelatedModel.objects.all())
```

resulting in SQL like `"related_id IN (SELECT id FROM ...)"`.

This implicit `__in` no longer happens so the “IN” SQL is now “=”, and if the subquery returns multiple results, at least some databases will throw an error.

contrib.admin browser support

The admin no longer supports Internet Explorer 8 and below, as these browsers have reached end-of-life.

CSS and images to support Internet Explorer 6 and 7 have been removed. PNG and GIF icons have been replaced with SVG icons, which are not supported by Internet Explorer 8 and earlier.

The jQuery library embedded in the admin has been upgraded from version 1.11.2 to 2.1.4. jQuery 2.x has the same API as jQuery 1.x, but does not support Internet Explorer 6, 7, or 8, allowing for better performance and a smaller file size. If you need to support IE8 and must also use the latest version of Django, you can override the admin's copy of jQuery with your own by creating a Django application with this structure:

```
app/static/admin/js/vendor/  
    jquery.js  
    jquery.min.js
```

SyntaxError when installing Django setuptools 5.5.x

When installing Django 1.9 or 1.9.1 with setuptools 5.5.x, you'll see:

```
Compiling django/conf/app_template/apps.py ...  
File "django/conf/app_template/apps.py", line 4  
    class {{ camel_case_app_name }}Config(AppConfig):  
        ^  
SyntaxError: invalid syntax  
  
Compiling django/conf/app_template/models.py ...  
File "django/conf/app_template/models.py", line 1  
    {{ unicode_literals }}from django.db import models  
        ^  
SyntaxError: invalid syntax
```

It's safe to ignore these errors (Django will still install just fine), but you can avoid them by upgrading setuptools to a more recent version. If you're using pip, you can upgrade pip using `python -m pip install -U pip` which will also upgrade setuptools. This is resolved in later versions of Django as described in the Django 1.9.2 release notes.

Miscellaneous

- The jQuery static files in `contrib.admin` have been moved into a `vendor/jquery` subdirectory.
- The text displayed for null columns in the admin changelist `list_display` cells has changed from `(None)` (or its translated equivalent) to `-` (a dash).
- `django.http.responses.REASON_PHRASES` and `django.core.handlers.wsgi.STATUS_CODE_TEXT` have been removed. Use Python's Standard Library instead: `http.client.responses` for Python 3 and `httplib.responses` for Python 2.
- `ValuesQuerySet` and `ValuesListQuerySet` have been removed.
- The `admin/base.html` template no longer sets `window.__admin_media_prefix__` or `window.__admin_utc_offset__`. Image references in JavaScript that used that value to construct absolute URLs have been moved to CSS for easier customization. The UTC offset is stored on a data attribute of the `<body>` tag.
- `CommaSeparatedIntegerField` validation has been refined to forbid values like `' , '`, `' ,1 '`, and `' 1 , 2 '`.
- Form initialization was moved from the `ProcessFormView.get()` method to the new `FormMixin.get_context_data()` method. This may be backwards incompatible if you have overridden the `get_context_data()` method without calling `super()`.
- Support for PostGIS 1.5 has been dropped.
- The `django.contrib.sites.models.Site.domain` field was changed to be *unique*.
- In order to enforce test isolation, database queries are not allowed by default in `SimpleTestCase` tests anymore. You can disable this behavior by setting the `allow_database_queries` class attribute to `True` on your test class.
- `ResolverMatch.app_name` was changed to contain the full namespace path in the case of nested namespaces. For consistency with `ResolverMatch.namespace`, the empty value is now an empty string instead of `None`.
- For security hardening, session keys must be at least 8 characters.
- Private function `django.utils.functional.total_ordering()` has been removed. It contained a workaround for a `functools.total_ordering()` bug in Python versions older than 2.7.3.
- XML serialization (either through *dumpdata* or the syndication framework) used to output any characters it received. Now if the content to be serialized contains any control characters not allowed in the XML 1.0 standard, the serialization will fail with a `ValueError`.
- *CharField* now strips input of leading and trailing whitespace by default. This can be disabled by setting the new *strip* argument to `False`.
- Template text that is translated and uses two or more consecutive percent signs, e.g. `"%"`, may have a new `msgid` after `makemessages` is run (most likely the translation will be marked fuzzy). The new `msgid` will be marked `"#, python-format"`.

- If neither `request.current_app` nor `Context.current_app` are set, the `url` template tag will now use the namespace of the current request. Set `request.current_app` to `None` if you don't want to use a namespace hint.
- The `SILENCED_SYSTEM_CHECKS` setting now silences messages of all levels. Previously, messages of `ERROR` level or higher were printed to the console.
- The `FlatPage.enable_comments` field is removed from the `FlatPageAdmin` as it's unused by the application. If your project or a third-party app makes use of it, [create a custom ModelAdmin](#) to add it back.
- The return value of `setup_databases()` and the first argument of `teardown_databases()` changed. They used to be `(old_names, mirrors)` tuples. Now they're just the first item, `old_names`.
- By default `LiveServerTestCase` attempts to find an available port in the 8081-8179 range instead of just trying port 8081.
- The system checks for `ModelAdmin` now check instances rather than classes.
- The private API to apply mixed migration plans has been dropped for performance reasons. Mixed plans consist of a list of migrations where some are being applied and others are being unapplied.
- The related model object descriptor classes in `django.db.models.fields.related` (private API) are moved from the `related` module to `related_descriptors` and renamed as follows:
 - `ReverseSingleRelatedObjectDescriptor` is `ForwardManyToOneDescriptor`
 - `SingleRelatedObjectDescriptor` is `ReverseOneToOneDescriptor`
 - `ForeignRelatedObjectsDescriptor` is `ReverseManyToOneDescriptor`
 - `ManyRelatedObjectsDescriptor` is `ManyToManyDescriptor`
- If you implement a custom `handler404` view, it must return a response with an HTTP 404 status code. Use `HttpResponseNotFound` or pass `status=404` to the `HttpResponse`. Otherwise, `APPEND_SLASH` won't work correctly with `DEBUG=False`.

Features deprecated in 1.9

`assignment_tag()`

Django 1.4 added the `assignment_tag` helper to ease the creation of template tags that store results in a template variable. The `simple_tag()` helper has gained this same ability, making the `assignment_tag` obsolete. Tags that use `assignment_tag` should be updated to use `simple_tag`.

`{% cycle %}` syntax with comma-separated arguments

The `cycle` tag supports an inferior old syntax from previous Django versions:

```
{% cycle row1,row2,row3 %}
```

Its parsing caused bugs with the current syntax, so support for the old syntax will be removed in Django 1.10 following an accelerated deprecation.

ForeignKey and OneToOneField on_delete argument

In order to increase awareness about cascading model deletion, the `on_delete` argument of `ForeignKey` and `OneToOneField` will be required in Django 2.0.

Update models and existing migrations to explicitly set the argument. Since the default is `models.CASCADE`, add `on_delete=models.CASCADE` to all `ForeignKey` and `OneToOneFields` that don't use a different option. You can also pass it as the second positional argument if you don't care about compatibility with older versions of Django.

Field.rel changes

`Field.rel` and its methods and attributes have changed to match the related fields API. The `Field.rel` attribute is renamed to `remote_field` and many of its methods and attributes are either changed or renamed.

The aim of these changes is to provide a documented API for relation fields.

GeoManager and GeoQuerySet custom methods

All custom `GeoQuerySet` methods (`area()`, `distance()`, `gml()`, ...) have been replaced by equivalent geographic expressions in annotations (see in new features). Hence the need to set a custom `GeoManager` to GIS-enabled models is now obsolete. As soon as your code doesn't call any of the deprecated methods, you can simply remove the `objects = GeoManager()` lines from your models.

Template loader APIs have changed

Django template loaders have been updated to allow recursive template extending. This change necessitated a new template loader API. The old `load_template()` and `load_template_sources()` methods are now deprecated. Details about the new API can be found in [the template loader documentation](#).

Passing a 3-tuple or an `app_name` to `include()`

The instance namespace part of passing a tuple as an argument to `include()` has been replaced by passing the `namespace` argument to `include()`. For example:

```
polls_patterns = [
    url(...),
]

urlpatterns = [
    url(r"^polls/", include((polls_patterns, "polls", "author-polls"))),
]
```

becomes:

```
polls_patterns = (
    [
        url(...),
    ],
    "polls",
) # 'polls' is the app_name

urlpatterns = [
    url(r"^polls/", include(polls_patterns, namespace="author-polls")),
]
```

The `app_name` argument to `include()` has been replaced by passing a 2-tuple (as above), or passing an object or module with an `app_name` attribute (as below). If the `app_name` is set in this new way, the `namespace` argument is no longer required. It will default to the value of `app_name`. For example, the URL patterns in the tutorial are changed from:

Listing 1: `mysite/urls.py`

```
urlpatterns = [url(r"^polls/", include("polls.urls", namespace="polls")), ...]
```

to:

Listing 2: `mysite/urls.py`

```
urlpatterns = [
    url(r"^polls/", include("polls.urls")), # 'namespace="polls"' removed
    ...,
]
```

Listing 3: polls/urls.py

```
app_name = "polls" # added
urlpatterns = [...]
```

This change also means that the old way of including an `AdminSite` instance is deprecated. Instead, pass `admin.site.urls` directly to `django.conf.urls.url()`:

Listing 4: urls.py

```
from django.conf.urls import url
from django.contrib import admin

urlpatterns = [
    url(r"^admin/", admin.site.urls),
]
```

URL application namespace required if setting an instance namespace

In the past, an instance namespace without an application namespace would serve the same purpose as the application namespace, but it was impossible to reverse the patterns if there was an application namespace with the same name. Includes that specify an instance namespace require that the included `URLconf` sets an application namespace.

`current_app` parameter to `contrib.auth` views

All views in `django.contrib.auth.views` have the following structure:

```
def view(request, ..., current_app=None, ...):
    ...

    if current_app is not None:
        request.current_app = current_app

    return TemplateResponse(request, template_name, context)
```

As of Django 1.8, `current_app` is set on the `request` object. For consistency, these views will require the caller to set `current_app` on the `request` instead of passing it in a separate argument.

`django.contrib.gis.geoip`

The `django.contrib.gis.geoip2` module supersedes `django.contrib.gis.geoip`. The new module provides a similar API except that it doesn't provide the legacy GeoIP-Python API compatibility methods.

Miscellaneous

- The `weak` argument to `django.dispatch.signals.Signal.disconnect()` has been deprecated as it has no effect.
- The `check_aggregate_support()` method of `django.db.backends.base.BaseDatabaseOperations` has been deprecated and will be removed in Django 2.0. The more general `check_expression_support()` should be used instead.
- `django.forms.extras` is deprecated. You can find `SelectDateWidget` in `django.forms.widgets` (or simply `django.forms`) instead.
- Private API `django.db.models.fields.add_lazy_relation()` is deprecated.
- The `django.contrib.auth.tests.utils.skipIfCustomUser()` decorator is deprecated. With the test discovery changes in Django 1.6, the tests for `django.contrib` apps are no longer run as part of the user's project. Therefore, the `@skipIfCustomUser` decorator is no longer needed to decorate tests in `django.contrib.auth`.
- If you customized some [error handlers](#), the view signatures with only one request parameter are deprecated. The views should now also accept a second `exception` positional parameter.
- The `django.utils.feedgenerator.Atom1Feed.mime_type` and `django.utils.feedgenerator.RssFeed.mime_type` attributes are deprecated in favor of `content_type`.
- *Signer* now issues a warning if an invalid separator is used. This will become an exception in Django 1.10.
- `django.db.models.Field._get_val_from_obj()` is deprecated in favor of `Field.value_from_object()`.
- `django.template.loaders.eggs.Loader` is deprecated as distributing applications as eggs is not recommended.
- The `callable_obj` keyword argument to `SimpleTestCase.assertRaisesMessage()` is deprecated. Pass the callable as a positional argument instead.
- The `allow_tags` attribute on methods of `ModelAdmin` has been deprecated. Use `format_html()`, `format_html_join()`, or `mark_safe()` when constructing the method's return value instead.
- The `enclosure` keyword argument to `SyndicationFeed.add_item()` is deprecated. Use the new `enclosures` argument which accepts a list of `Enclosure` objects instead of a single one.

- The `django.template.loader.LoaderOrigin` and `django.template.base.StringOrigin` aliases for `django.template.base.Origin` are deprecated.

Features removed in 1.9

These features have reached the end of their deprecation cycle and are removed in Django 1.9. See [Features deprecated in 1.7](#) for details, including how to remove usage of these features.

- `django.utils.dictconfig` is removed.
- `django.utils.importlib` is removed.
- `django.utils.tzinfo` is removed.
- `django.utils.unittest` is removed.
- The `syncdb` command is removed.
- `django.db.models.signals.pre_syncdb` and `django.db.models.signals.post_syncdb` is removed.
- Support for `allow_syncdb` on database routers is removed.
- Automatic syncing of apps without migrations is removed. Migrations are compulsory for all apps unless you pass the `migrate --run-syncdb` option.
- The SQL management commands for apps without migrations, `sql`, `sqlall`, `sqlclear`, `sqldropindexes`, and `sqlindexes`, are removed.
- Support for automatic loading of `initial_data` fixtures and initial SQL data is removed.
- All models need to be defined inside an installed application or declare an explicit `app_label`. Furthermore, it isn't possible to import them before their application is loaded. In particular, it isn't possible to import models inside the root package of an application.
- The model and form `IPAddressField` is removed. A stub field remains for compatibility with historical migrations.
- `AppCommand.handle_app()` is no longer supported.
- `RequestSite` and `get_current_site()` are no longer importable from `django.contrib.sites.models`.
- FastCGI support via the `runfcgi` management command is removed.
- `django.utils.datastructures.SortedDict` is removed.
- `ModelAdmin.declared_fieldsets` is removed.
- The util modules that provided backwards compatibility are removed:
 - `django.contrib.admin.util`
 - `django.contrib.gis.db.backends.util`

- `django.db.backends.util`
 - `django.forms.util`
- `ModelAdmin.get_formsets` is removed.
- The backward compatible shims introduced to rename the `BaseMemcachedCache._get_memcache_timeout()` method to `get_backend_timeout()` is removed.
- The `--natural` and `-n` options for *dumpdata* are removed.
- The `use_natural_keys` argument for `serializers.serialize()` is removed.
- Private API `django.forms.forms.get_declared_fields()` is removed.
- The ability to use a `SplitDateTimeWidget` with `DateTimeField` is removed.
- The `WSGIRequest.REQUEST` property is removed.
- The class `django.utils.datastructures.MergeDict` is removed.
- The `zh-cn` and `zh-tw` language codes are removed.
- The internal `django.utils.functional.memoize()` is removed.
- `django.core.cache.get_cache` is removed.
- `django.db.models.loading` is removed.
- Passing callable arguments to queriesets is no longer possible.
- `BaseCommand.requires_model_validation` is removed in favor of `requires_system_checks`. Admin validators is replaced by admin checks.
- The `ModelAdmin.validator_class` and `default_validator_class` attributes are removed.
- `ModelAdmin.validate()` is removed.
- `django.db.backends.DatabaseValidation.validate_field` is removed in favor of the `check_field` method.
- The `validate` management command is removed.
- `django.utils.module_loading.import_by_path` is removed in favor of `django.utils.module_loading.import_string`.
- `ssi` and `url` template tags are removed from the future template tag library.
- `django.utils.text.javascript_quote()` is removed.
- Database test settings as independent entries in the database settings, prefixed by `TEST_`, are no longer supported.
- The `cache_choices` option to *ModelChoiceField* and *ModelMultipleChoiceField* is removed.
- The default value of the *RedirectView*.*permanent* attribute has changed from `True` to `False`.

- `django.contrib.sitemaps.FlatPageSitemap` is removed in favor of `django.contrib.flatpages.sitemaps.FlatPageSitemap`.
- Private API `django.test.utils.TestTemplateLoader` is removed.
- The `django.contrib.contenttypes.generic` module is removed.

9.1.13 1.8 release

Django 1.8.19 release notes

March 6, 2018

Django 1.8.19 fixes two security issues in 1.8.18.

CVE-2018-7536: Denial-of-service possibility in `urlize` and `urlizetrunc` template filters

The `django.utils.html.urlize()` function was extremely slow to evaluate certain inputs due to a catastrophic backtracking vulnerability in a regular expression. The `urlize()` function is used to implement the `urlize` and `urlizetrunc` template filters, which were thus vulnerable.

The problematic regular expression is replaced with parsing logic that behaves similarly.

CVE-2018-7537: Denial-of-service possibility in `truncatechars_html` and `truncatewords_html` template filters

If `django.utils.text.Truncator`'s `chars()` and `words()` methods were passed the `html=True` argument, they were extremely slow to evaluate certain inputs due to a catastrophic backtracking vulnerability in a regular expression. The `chars()` and `words()` methods are used to implement the `truncatechars_html` and `truncatewords_html` template filters, which were thus vulnerable.

The backtracking problem in the regular expression is fixed.

Django 1.8.18 release notes

April 4, 2017

Django 1.8.18 fixes two security issues in 1.8.17.

CVE-2017-7233: Open redirect and possible XSS attack via user-supplied numeric redirect URLs

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()` and [i18n](#)) to redirect the user to an “on success” URL. The security check for these redirects (namely `django.utils.http.is_safe_url()`) considered some numeric URLs (e.g. `http:999999999`) “safe” when they shouldn’t be.

Also, if a developer relies on `is_safe_url()` to provide safe redirect targets and puts such a URL into a link, they could suffer from an XSS attack.

CVE-2017-7234: Open redirect vulnerability in `django.views.static.serve()`

A maliciously crafted URL to a Django site using the `serve()` view could redirect to any other domain. The view no longer does any redirects as they don’t provide any known, useful functionality.

Note, however, that this view has always carried a warning that it is not hardened for production use and should be used only as a development aid.

Django 1.8.17 release notes

December 1, 2016

Django 1.8.17 fixes a regression in 1.8.16.

Bugfixes

- Quoted the Oracle test user’s password in queries to fix the “ORA-00922: missing or invalid option” error when the password starts with a number or special character ([#27420](#)).

Django 1.8.16 release notes

November 1, 2016

Django 1.8.16 fixes two security issues in 1.8.15.

User with hardcoded password created when running tests on Oracle

When running tests with an Oracle database, Django creates a temporary database user. In older versions, if a password isn’t manually specified in the database settings `TEST` dictionary, a hardcoded password is used. This could allow an attacker with network access to the database server to connect.

This user is usually dropped after the test suite completes, but not when using the `manage.py test --keepdb` option or if the user has an active session (such as an attacker’s connection).

A randomly generated password is now used for each test run.

DNS rebinding vulnerability when `DEBUG=True`

Older versions of Django don't validate the `Host` header against `settings.ALLOWED_HOSTS` when `settings.DEBUG=True`. This makes them vulnerable to a [DNS rebinding attack](#).

While Django doesn't ship a module that allows remote code execution, this is at least a cross-site scripting vector, which could be quite serious if developers load a copy of the production database in development or connect to some production services for which there's no development instance, for example. If a project uses a package like the `django-debug-toolbar`, then the attacker could execute arbitrary SQL, which could be especially bad if the developers connect to the database with a superuser account.

`settings.ALLOWED_HOSTS` is now validated regardless of `DEBUG`. For convenience, if `ALLOWED_HOSTS` is empty and `DEBUG=True`, the following variations of `localhost` are allowed `['localhost', '127.0.0.1', '::1']`. If your local settings file has your production `ALLOWED_HOSTS` value, you must now omit it to get those fallback values.

Django 1.8.15 release notes

September 26, 2016

Django 1.8.15 fixes a security issue in 1.8.14.

CSRF protection bypass on a site with Google Analytics

An interaction between Google Analytics and Django's cookie parsing could allow an attacker to set arbitrary cookies leading to a bypass of CSRF protection.

The parser for `request.COOKIES` is simplified to better match the behavior of browsers and to mitigate this attack. `request.COOKIES` may now contain cookies that are invalid according to [RFC 6265](#) but are possible to set via `document.cookie`.

Django 1.8.14 release notes

July 18, 2016

Django 1.8.14 fixes a security issue and a bug in 1.8.13.

XSS in admin' s add/change related popup

Unsafe usage of JavaScript' s `Element.innerHTML` could result in XSS in the admin' s add/change related popup. `Element.textContent` is now used to prevent execution of the data.

The debug view also used `innerHTML`. Although a security issue wasn' t identified there, out of an abundance of caution it' s also updated to use `textContent`.

Bugfixes

- Fixed missing `varchar/text_pattern_ops` index on `CharField` and `TextField` respectively when using `AddField` on PostgreSQL (#26889).

Django 1.8.13 release notes

May 2, 2016

Django 1.8.13 fixes several bugs in 1.8.12.

Bugfixes

- Fixed `TimeField` microseconds round-tripping on MySQL and SQLite (#26498).
- Restored conversion of an empty string to null when saving values of `GenericIPAddressField` on SQLite and MySQL (#26557).

Django 1.8.12 release notes

April 1, 2016

Django 1.8.12 fixes several bugs in 1.8.11.

Bugfixes

- Made `MultiPartParser` ignore filenames that normalize to an empty string to fix crash in `MemoryFileUploadHandler` on specially crafted user input (#26325).
- Fixed data loss on SQLite where `DurationField` values with fractional seconds could be saved as `None` (#26324).
- Restored the functionality of the admin' s `raw_id_fields` in `list_editable` (#26387).

Django 1.8.11 release notes

March 5, 2016

Django 1.8.11 fixes a regression on Python 2 in the 1.8.10 security release where `utils.http.is_safe_url()` crashes on bytestring URLs (#26308).

Django 1.8.10 release notes

March 1, 2016

Django 1.8.10 fixes two security issues and several bugs in 1.8.9.

CVE-2016-2512: Malicious redirect and possible XSS attack via user-supplied redirect URLs containing basic auth

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()` and [i18n](#)) to redirect the user to an “on success” URL. The security check for these redirects (namely `django.utils.http.is_safe_url()`) considered some URLs with basic authentication credentials “safe” when they shouldn’t be.

For example, a URL like `http://mysite.example.com\@attacker.com` would be considered safe if the request’s host is `http://mysite.example.com`, but redirecting to this URL sends the user to `attacker.com`.

Also, if a developer relies on `is_safe_url()` to provide safe redirect targets and puts such a URL into a link, they could suffer from an XSS attack.

CVE-2016-2513: User enumeration through timing difference on password hasher work factor upgrade

In each major version of Django since 1.6, the default number of iterations for the `PBKDF2PasswordHasher` and its subclasses has increased. This improves the security of the password as the speed of hardware increases, however, it also creates a timing difference between a login request for a user with a password encoded in an older number of iterations and login request for a nonexistent user (which runs the default hasher’s default number of iterations since Django 1.6).

This only affects users who haven’t logged in since the iterations were increased. The first time a user logs in after an iterations increase, their password is updated with the new iterations and there is no longer a timing difference.

The new `BasePasswordHasher.harden_runtime()` method allows hashers to bridge the runtime gap between the work factor (e.g. iterations) supplied in existing encoded passwords and the default work factor of the hasher. This method is implemented for `PBKDF2PasswordHasher` and `BCryptPasswordHasher`. The number of rounds for the latter hasher hasn’t changed since Django 1.4, but some projects may subclass it and increase the work factor as needed.

A warning will be emitted for any [third-party password hashers that don't implement](#) a `harden_runtime()` method.

If you have different password hashes in your database (such as SHA1 hashes from users who haven't logged in since the default hasher switched to PBKDF2 in Django 1.4), the timing difference on a login request for these users may be even greater and this fix doesn't remedy that difference (or any difference when changing hashers). You may be able to [upgrade those hashes](#) to prevent a timing attack for that case.

Bugfixes

- Fixed a crash on PostgreSQL that prevented using `TIME_ZONE=None` and `USE_TZ=False` ([#26177](#)).
- Added system checks for query name clashes of hidden relationships ([#26162](#)).
- Made `forms.FileField` and `utils.translation.lazy_number()` picklable ([#26212](#)).
- Fixed [RangeField](#) and [ArrayField](#) serialization with `None` values ([#26215](#)).
- Reallowed dashes in top-level domain names of URLs checked by `URLValidator` to fix a regression in Django 1.8 ([#26204](#)).
- Fixed `BoundField` to reallow slices of subwidgets ([#26267](#)).
- Prevented `ContentTypeManager` instances from sharing their cache ([#26286](#)).

Django 1.8.9 release notes

February 1, 2016

Django 1.8.9 fixes several bugs in 1.8.8.

Bugfixes

- Fixed a regression that caused the “user-tools” items to display on the admin's logout page ([#26035](#)).
- Fixed a crash in the translations system when the current language has no translations ([#26046](#)).
- Fixed a regression that caused the incorrect day to be selected when opening the admin calendar widget for timezones from GMT+0100 to GMT+1200 ([#24980](#)).
- Fixed a regression in 1.8.8 causing incorrect index handling in migrations on PostgreSQL when adding `db_index=True` or `unique=True` to a `CharField` or `TextField` that already had the other specified, or when removing one of them from a field that had both, or when adding `unique=True` to a field already listed in `unique_together` ([#26034](#)).
- Fixed a crash when using an `__in` lookup inside a `Case` expression ([#26071](#)).
- Fixed a crash when using a reverse `OneToOneField` in `ModelAdmin.readonly_fields` ([#26060](#)).

- Fixed a regression in Django 1.8.5 that broke copying a `SimpleLazyObject` with `copy.copy()` (#26122).
- Fixed the `contrib.gis` map widgets when using `USE_THOUSAND_SEPARATOR=True` (#20415).

Django 1.8.8 release notes

January 2, 2016

Django 1.8.8 fixes several bugs in 1.8.7.

Python 3.2 users, please be advised that we've decided to drop support for Python 3.2 in Django 1.8.x at the end of 2016. We won't break things intentionally after that, but we won't test subsequent releases against Python 3.2 either. Upstream support for Python 3.2 ends February 2016 so we don't find much value in providing security updates for a version of Python that could be insecure. To read more about the decision and to let us know if this will be problematic for you, please read the [django-developers thread](#).

Bugfixes

- Fixed incorrect `unique_together` field name generation by `inspectdb` (#25274).
- Corrected `__len` query lookup on `ArrayField` for empty arrays (#25772).
- Restored the ability to use custom formats from `formats.py` with `django.utils.formats.get_format()` and the `date` template filter (#25812).
- Fixed a state bug when migrating a `SeparateDatabaseAndState` operation backwards (#25896).
- Fixed missing `varchar/text_pattern_ops` index on `CharField` and `TextField` respectively when using `AlterField` on PostgreSQL (#25412).
- Fixed a state bug when using an `AlterModelManagers` operation (#25852).
- Fixed a regression which prevented using a language not in Django's default language list (`LANGUAGES`) (#25915).
- `django.views.decorators.cache.never_cache()` now sends more persuasive headers (added `no-cache`, `no-store`, `must-revalidate` to `Cache-Control`) to better prevent caching (#13008). This fixes a problem where a page refresh in Firefox cleared the selected entries in the admin's `filter_horizontal` and `filter_vertical` widgets, which could result in inadvertent data loss if a user didn't notice that and then submitted the form (#22955).
- Fixed a regression in the admin which ignored line breaks in read-only fields instead of converting them to `<br>` (#25465).
- Made `loaddata` skip disabling and enabling database constraints when it doesn't load any fixtures (#23372).
- Fixed a crash in `QuerySet.values()/values_list()` after an `annotate()` and `order_by()` when `values()/values_list()` includes a field not in the `order_by()` (#25316).

Django 1.8.7 release notes

November 24, 2015

Django 1.8.7 fixes a security issue and several bugs in 1.8.6.

Additionally, Django's vendored version of six, `django.utils.six`, has been upgraded to the latest release (1.10.0).

Fixed settings leak possibility in date template filter

If an application allows users to specify an unvalidated format for dates and passes this format to the `date` filter, e.g. `{{ last_updated|date:user_date_format }}`, then a malicious user could obtain any secret in the application's settings by specifying a settings key instead of a date format. e.g. "SECRET_KEY" instead of "j/m/Y".

To remedy this, the underlying function used by the `date` template filter, `django.utils.formats.get_format()`, now only allows accessing the date/time formatting settings.

Bugfixes

- Fixed a crash of the debug view during the autumn DST change when `USE_TZ` is `False` and `pytz` is installed.
- Fixed a regression in 1.8.6 that caused database routers without an `allow_migrate()` method to crash (#25686).
- Fixed a regression in 1.8.6 by restoring the ability to use `Manager` objects for the `queryset` argument of `ModelChoiceField` (#25683).
- Fixed a regression in 1.8.6 that caused an application with South migrations in the `migrations` directory to fail (#25618).
- Fixed a data loss possibility with `Prefetch` if `to_attr` is set to a `ManyToManyField` (#25693).
- Fixed a regression in 1.8 by making `gettext()` once again return UTF-8 bytestrings on Python 2 if the input is a bytestring (#25720).
- Fixed serialization of `DateRangeField` and `DateTimeRangeField` (#24937).
- Fixed the exact lookup of `ArrayField` (#25666).
- Fixed `Model.refresh_from_db()` updating of `ForeignKey` fields with `on_delete=models.SET_NULL` (#25715).
- Fixed a duplicate query regression in 1.8 on proxied model deletion (#25685).
- Fixed `set_FOO_order()` crash when the `ForeignKey` of a model with `order_with_respect_to` references a model with a `OneToOneField` primary key (#25786).

- Fixed incorrect validation for `PositiveIntegerField` and `PositiveSmallIntegerField` on MySQL resulting in values greater than 4294967295 or 65535, respectively, passing validation and being silently truncated by the database ([#25767](#)).

Django 1.8.6 release notes

November 4, 2015

Django 1.8.6 adds official support for Python 3.5 and fixes several bugs in 1.8.5.

Bugfixes

- Fixed a regression causing `ModelChoiceField` to ignore `prefetch_related()` on its queryset ([#25496](#)).
- Allowed “mode=memory” in SQLite test database name if supported ([#12118](#)).
- Fixed system check crash on `ForeignKey` to abstract model ([#25503](#)).
- Fixed incorrect queries when you have multiple `ManyToManyFields` on different models that have the same field name, point to the same model, and have their reverse relations disabled ([#25545](#)).
- Allowed filtering over a `RawSQL` annotation ([#25506](#)).
- Made the `Concat` database function idempotent on SQLite ([#25517](#)).
- Avoided a confusing stack trace when starting `runserver` with an invalid `INSTALLED_APPS` setting ([#25510](#)). This regression appeared in 1.8.5 as a side effect of fixing [#24704](#).
- Made deferred models use their proxied model’s `_meta.apps` for caching and retrieval ([#25563](#)). This prevents any models generated in data migrations using `QuerySet.defer()` from leaking to test and application code.
- Fixed a typo in the name of the `strictly_above` PostGIS lookup ([#25592](#)).
- Fixed crash with `contrib.postgres.forms.SplitArrayField` and `IntegerField` on invalid value ([#25597](#)).
- Added a helpful error message when Django and South migrations exist in the same directory ([#25618](#)).
- Fixed a regression in `URLValidator` that allowed URLs with consecutive dots in the domain section (like `http://example..com/`) to pass ([#25620](#)).
- Fixed a crash with `GenericRelation` and `BaseModelAdmin.to_field_allowed` ([#25622](#)).

Django 1.8.5 release notes

October 3, 2015

Django 1.8.5 fixes several bugs in 1.8.4.

Bugfixes

- Made the development server's autoreload more robust (#24704).
- Fixed `AssertionError` in some delete queries with a model containing a field that is both a foreign and primary key (#24951).
- Fixed `AssertionError` in some complex queries (#24525).
- Fixed a migrations crash with `GenericForeignKey` (#25040).
- Made `translation.override()` clear the overridden language when a translation isn't initially active (#25295).
- Fixed crash when using a value in `ModelAdmin.list_display` that clashed with a reverse field on the model (#25299).
- Fixed autocompletion for options of non-`argparse` management commands (#25372).
- Alphabetized ordering of imports in `from django.db import migrations, models` statement in newly created migrations (#25384).
- Fixed migrations crash on MySQL when adding a text or a blob field with an unhashable default (#25393).
- Changed Count queries to execute `COUNT(*)` instead of `COUNT(' *')` as versions of Django before 1.8 did (#25377). This may fix a performance regression on some databases.
- Fixed custom queryset chaining with `values()` and `values_list()` (#20625).
- Moved the [unsaved model instance assignment data loss check](#) on reverse relations to `Model.save()` (#25160).
- Readded inline foreign keys to form instances when validating model formsets (#25431).
- Allowed using ORM write methods after disabling autocommit with `set_autocommit(False)` (#24921).
- Fixed the `manage.py test --keepdb` option on Oracle (#25421).
- Fixed incorrect queries with multiple many-to-many fields on a model with the same 'to' model and with `related_name` set to '+' (#24505, #25486).
- Fixed pickling a `SimpleLazyObject` wrapping a model (#25389).

Django 1.8.4 release notes

August 18, 2015

Django 1.8.4 fixes a security issue and several bugs in 1.8.3.

Denial-of-service possibility in `logout()` view by filling session store

Previously, a session could be created when anonymously accessing the `django.contrib.auth.views.logout()` view (provided it wasn't decorated with `login_required()` as done in the admin). This could allow an attacker to easily create many new session records by sending repeated requests, potentially filling up the session store or causing other users' session records to be evicted.

The `SessionMiddleware` has been modified to no longer create empty session records, including when `SESSION_SAVE_EVERY_REQUEST` is active.

Bugfixes

- Added the ability to serialize values from the newly added `UUIDField` (#25019).
- Added a system check warning if the old `TEMPLATE_*` settings are defined in addition to the new `TEMPLATES` setting.
- Fixed `QuerySet.raw()` so `InvalidQuery` is not raised when using the `db_column` name of a `ForeignKey` field with `primary_key=True` (#12768).
- Prevented an exception in `TestCase.setUpTestData()` from leaking the transaction (#25176).
- Fixed `has_changed()` method in `contrib.postgres.forms.HStoreField` (#25215, #25233).
- Fixed the recording of squashed migrations when running the `migrate` command (#25231).
- Moved the `unsaved model instance assignment data loss check` to `Model.save()` to allow easier usage of in-memory models (#25160).
- Prevented `varchar_patterns_ops` and `text_patterns_ops` indexes for `ArrayField` (#25180).

Django 1.8.3 release notes

July 8, 2015

Django 1.8.3 fixes several security issues and bugs in 1.8.2.

Also, `django.utils.deprecation.RemovedInDjango20Warning` was renamed to `RemovedInDjango110Warning` as the version roadmap was revised to 1.9, 1.10, 1.11 (LTS), 2.0 (drops Python 2 support). For backwards compatibility, `RemovedInDjango20Warning` remains as an importable alias.

Denial-of-service possibility by filling session store

In previous versions of Django, the session backends created a new empty record in the session storage any-time `request.session` was accessed and there was a session key provided in the request cookies that didn't already have a session record. This could allow an attacker to easily create many new session records simply by sending repeated requests with unknown session keys, potentially filling up the session store or causing other users' session records to be evicted.

The built-in session backends now create a session record only if the session is actually modified; empty session records are not created. Thus this potential DoS is now only possible if the site chooses to expose a session-modifying view to anonymous users.

As each built-in session backend was fixed separately (rather than a fix in the core sessions framework), maintainers of third-party session backends should check whether the same vulnerability is present in their backend and correct it if so.

Header injection possibility since validators accept newlines in input

Some of Django's built-in validators (*EmailValidator*, most seriously) didn't prohibit newline characters (due to the usage of `$` instead of `\Z` in the regular expressions). If you use values with newlines in HTTP response or email headers, you can suffer from header injection attacks. Django itself isn't vulnerable because *HttpResponse* and the mail sending utilities in *django.core.mail* prohibit newlines in HTTP and SMTP headers, respectively. While the validators have been fixed in Django, if you're creating HTTP responses or email messages in other ways, it's a good idea to ensure that those methods prohibit newlines as well. You might also want to validate that any existing data in your application doesn't contain unexpected newlines.

validate_ipv4_address(), *validate_slug()*, and *URLValidator* are also affected, however, as of Django 1.6 the *GenericIPAddressField*, *IPAddressField*, *SlugField*, and *URLField* form fields which use these validators all strip the input, so the possibility of newlines entering your data only exists if you are using these validators outside of the form fields.

The undocumented, internally unused *validate_integer()* function is now stricter as it validates using a regular expression instead of simply casting the value using *int()* and checking if an exception was raised.

Denial-of-service possibility in URL validation

URLValidator included a regular expression that was extremely slow to evaluate against certain invalid inputs. This regular expression has been simplified and optimized.

Bugfixes

- Fixed `BaseRangeField.prepare_value()` to use each `base_field`'s `prepare_value()` method (#24841).
- Fixed crash during *makemigrations* if a migrations module either is missing `__init__.py` or is a file (#24848).
- Fixed `QuerySet.exists()` returning incorrect results after annotation with `Count()` (#24835).
- Corrected `HStoreField.has_changed()` (#24844).
- Reverted an optimization to the CSRF template context processor which caused a regression (#24836).
- Fixed a regression which caused template context processors to overwrite variables set on a `RequestContext` after it's created (#24847).
- Prevented the loss of `null/not null` column properties during field renaming of MySQL databases (#24817).
- Fixed a crash when using a reverse one-to-one relation in `ModelAdmin.list_display` (#24851).
- Fixed quoting of SQL when renaming a field to `AutoField` in PostgreSQL (#24892).
- Fixed lack of unique constraint when changing a field from `primary_key=True` to `unique=True` (#24893).
- Fixed queryset pickling when using `prefetch_related()` after deleting objects (#24831).
- Allowed using choices longer than 1 day with `DurationField` (#24897).
- Fixed a crash when loading squashed migrations from two apps with a dependency between them, where the dependent app's replaced migrations are partially applied (#24895).
- Fixed recording of applied status for squashed (replacement) migrations (#24628).
- Fixed queryset annotations when using `Case` expressions with `exclude()` (#24833).
- Corrected join promotion for multiple `Case` expressions. Annotating a query with multiple `Case` expressions could unexpectedly filter out results (#24924).
- Fixed usage of transforms in subqueries (#24744).
- Fixed `SimpleTestCase.assertRaisesMessage()` on Python 2.7.10 (#24903).
- Provided better backwards compatibility for the `verbosity` argument in `optparse` management commands by casting it to an integer (#24769).
- Fixed `prefetch_related()` on databases other than PostgreSQL for models using UUID primary keys (#24912).
- Fixed removing `unique_together` constraints on MySQL (#24972).

- Fixed crash when uploading images with MIME types that Pillow doesn't detect, such as bitmap, in `forms.ImageField` (#24948).
- Fixed a regression when deleting a model through the admin that has a `GenericRelation` with a `related_query_name` (#24940).
- Reallowed non-ASCII values for `ForeignKey.related_name` on Python 3 by fixing the false positive system check (#25016).
- Fixed inline forms that use a parent object that has a `UUIDField` primary key and a child object that has an `AutoField` primary key (#24958).
- Fixed a regression in the `unordered_list` template filter on certain inputs (#25031).
- Fixed a regression in `URLValidator` that invalidated Punycode TLDs (#25059).
- Improved `pyinotify` `runserver` polling (#23882).

Django 1.8.2 release notes

May 20, 2015

Django 1.8.2 fixes a security issue and several bugs in 1.8.1.

Fixed session flushing in the `cached_db` backend

A change to `session.flush()` in the `cached_db` session backend in Django 1.8 mistakenly sets the session key to an empty string rather than `None`. An empty string is treated as a valid session key and the session cookie is set accordingly. Any users with an empty string in their session cookie will use the same session store. `session.flush()` is called by `django.contrib.auth.logout()` and, more seriously, by `django.contrib.auth.login()` when a user switches accounts. If a user is logged in and logs in again to a different account (without logging out) the session is flushed to avoid reuse. After the session is flushed (and its session key becomes `''`) the account details are set on the session and the session is saved. Any users with an empty string in their session cookie will now be logged into that account.

Bugfixes

- Fixed check for template engine alias uniqueness (#24685).
- Fixed crash when reusing the same `Case` instance in a query (#24752).
- Corrected join promotion for `Case` expressions. For example, annotating a query with a `Case` expression could unexpectedly filter out results (#24766).
- Fixed negated `Q` objects in expressions. Cases like `Case(When(~Q(friends__age__lte=30)))` tried to generate a subquery which resulted in a crash (#24705).

- Fixed incorrect GROUP BY clause generation on MySQL when the query’s model has a self-referential foreign key (#24748).
- Implemented `ForeignKey.get_db_prep_value()` so that ForeignKeys pointing to `UUIDField` and inheritance on models with `UUIDField` primary keys work correctly (#24698, #24712).
- Fixed `isnull` lookup for `HStoreField` (#24751).
- Fixed a MySQL crash when a migration removes a combined index (`unique_together` or `index_together`) containing a foreign key (#24757).
- Fixed session cookie deletion when using `SESSION_COOKIE_DOMAIN` (#24799).
- On PostgreSQL, when no access is granted for the `postgres` database, Django now falls back to the default database when it normally requires a “no database” connection (#24791).
- Fixed display of `contrib.admin`’s `ForeignKey` widget when it’s used in a row with other fields (#24784).

Django 1.8.1 release notes

May 1, 2015

Django 1.8.1 fixes several bugs in 1.8 and includes some optimizations in the migrations framework.

Bugfixes

- Added support for serializing `timedelta` objects in migrations (#24566).
- Restored proper parsing of the `testserver` command’s positional arguments (fixture names) (#24571).
- Prevented `TypeError` in translation functions `check_for_language()` and `get_language_bidi()` when translations are deactivated (#24569).
- Fixed `squashmigrations` command when using `SeparateDatabaseAndState` (#24278).
- Stripped microseconds from `datetime` values when using an older version of the MySQLdb DB API driver as it does not support fractional seconds (#24584).
- Fixed a migration crash when altering `ManyToManyFields` (#24513).
- Fixed a crash with `QuerySet.update()` on foreign keys to one-to-one fields (#24578).
- Fixed a regression in the model detail view of `admindocs` when a model has a reverse foreign key relation (#24624).
- Prevented arbitrary file inclusions in `admindocs` (#24625).
- Fixed a crash with `QuerySet.update()` on foreign keys to instances with `uuid` primary keys (#24611).
- Fixed database introspection with SQLite 3.8.9 (released April 8, 2015) (#24637).

- Updated `urlpatterns` examples generated by *startproject* to remove usage of referencing views by dotted path in `django.conf.urls.url()` which is deprecated in Django 1.8 (#24635).
- Fixed queries where an expression was referenced in `order_by()`, but wasn't part of the select clause. An example query is `qs.annotate(foo=F('field')).values('pk').order_by('foo')` (#24615).
- Fixed a database table name quoting regression (#24605).
- Prevented the loss of `null/not null` column properties during field alteration of MySQL databases (#24595).
- Fixed JavaScript path of `contrib.admin`'s related field widget when using alternate static file storages (#24655).
- Fixed a migration crash when adding new relations to models (#24573).
- Fixed a migration crash when applying migrations with model managers on Python 3 that were generated on Python 2 (#24701).
- Restored the ability to use iterators as queryset filter arguments (#24719).
- Fixed a migration crash when renaming the target model of a many-to-many relation (#24725).
- Removed flushing of the test database with *test --keepdb*, which prevented apps with data migrations from using the option (#24729).
- Fixed `makemessages` crash in some locales (#23271).
- Fixed help text positioning of `contrib.admin` fields that use the `ModelAdmin.filter_horizontal` and `filter_vertical` options (#24676).
- Fixed `AttributeError: function 'GDALAllRegister' not found` error when initializing `contrib.gis` on Windows.

Optimizations

- Changed `ModelState` to deepcopy fields instead of deconstructing and reconstructing (#24591). This speeds up the rendering of model states and reduces memory usage when running *manage.py migrate* (although other changes in this release may negate any performance benefits).

Django 1.8 release notes

April 1, 2015

Welcome to Django 1.8!

These release notes cover the [new features](#), as well as some [backwards incompatible changes](#) you'll want to be aware of when upgrading from Django 1.7 or older versions. We've also [begun the deprecation process](#) for [some features](#), and some features have reached the end of their deprecation process and [have been removed](#).

See the [How to upgrade Django to a newer version](#) guide if you’re updating an existing project.

Django 1.8 has been designated as Django’s second [long-term support release](#). It will receive security updates for at least three years after its release. Support for the previous LTS, Django 1.4, will end 6 months from the release date of Django 1.8.

Python compatibility

Django 1.8 requires Python 2.7, 3.2, 3.3, 3.4, or 3.5. We highly recommend and only officially support the latest release of each series.

Django 1.8 is the first release to support Python 3.5.

Due to the end of upstream support for Python 3.2 in February 2016, we won’t test Django 1.8.x on Python 3.2 after the end of 2016.

What’s new in Django 1.8

`Model._meta` API

Django now has a formalized API for `Model._meta`, providing an officially supported way to [retrieve fields](#) and filter fields based on their [attributes](#).

The `Model._meta` object has been part of Django since the days of pre-0.96 “Magic Removal”—it just wasn’t an official, stable API. In recognition of this, we’ve endeavored to maintain backwards-compatibility with the old API endpoint where possible. However, API endpoints that aren’t part of the new official API have been deprecated and will eventually be removed.

Multiple template engines

Django 1.8 defines a stable API for integrating template backends. It includes built-in support for the Django template language and for [Jinja2](#). It supports rendering templates with multiple engines within the same project. Learn more about the new features in the [topic guide](#) and check the upgrade instructions in older versions of the documentation.

Security enhancements

Several features of the `django-secure` third-party library have been integrated into Django. `django.middleware.security.SecurityMiddleware` provides several security enhancements to the request/response cycle. The new `check --deploy` option allows you to check your production settings file for ways to increase the security of your site.

New PostgreSQL specific functionality

Django now has a module with extensions for PostgreSQL specific features, such as *ArrayField*, *HStoreField*, Range Fields, and *unaccent* lookup. A full breakdown of the features is available in the [documentation](#).

New data types

- Django now has a *UUIDField* for storing universally unique identifiers. It is stored as the native `uuid` data type on PostgreSQL and as a fixed length character field on other backends. There is a corresponding *form field*.
- Django now has a *DurationField* for storing periods of time - modeled in Python by `timedelta`. It is stored in the native `interval` data type on PostgreSQL, as a `INTERVAL DAY(9) TO SECOND(6)` on Oracle, and as a `bigint` of microseconds on other backends. Date and time related arithmetic has also been improved on all backends. There is a corresponding *form field*.

Query Expressions, Conditional Expressions, and Database Functions

[Query Expressions](#) allow you to create, customize, and compose complex SQL expressions. This has enabled annotate to accept expressions other than aggregates. Aggregates are now able to reference multiple fields, as well as perform arithmetic, similar to `F()` objects. *order_by()* has also gained the ability to accept expressions.

[Conditional Expressions](#) allow you to use `if ... elif ... else` logic within queries.

A collection of [database functions](#) is also included with functionality such as *Coalesce*, *Concat*, and *Substr*.

TestCase data setup

TestCase has been refactored to allow for data initialization at the class level using transactions and save-points. Database backends which do not support transactions, like MySQL with the MyISAM storage engine, will still be able to run these tests but won't benefit from the improvements. Tests are now run within two nested *atomic()* blocks: one for the whole class and one for each test.

- The class method *TestCase.setUpTestData()* adds the ability to set up test data at the class level. Using this technique can speed up the tests as compared to using *setUp()*.
- Fixture loading within *TestCase* is now performed once for the whole *TestCase*.

Minor features

`django.contrib.admin`

- *ModelAdmin* now has a *has_module_permission()* method to allow limiting access to the module on the admin index page.
- *InlineModelAdmin* now has an attribute *show_change_link* that supports showing a link to an inline object's change form.
- Use the new `django.contrib.admin.RelatedOnlyFieldListFilter` in *ModelAdmin.list_filter* to limit the *list_filter* choices to foreign objects which are attached to those from the *ModelAdmin*.
- The *ModelAdmin.delete_view()* displays a summary of objects to be deleted on the deletion confirmation page.
- The jQuery library embedded in the admin has been upgraded to version 1.11.2.
- You can now specify *AdminSite.site_url* in order to display a link to the front-end site.
- You can now specify *ModelAdmin.show_full_result_count* to control whether or not the full count of objects should be displayed on a filtered admin page.
- The *AdminSite.password_change()* method now has an *extra_context* parameter.
- You can now control who may login to the admin site by overriding only *AdminSite.has_permission()* and *AdminSite.login_form*. The `base.html` template has a new block `usertools` which contains the user-specific header. A new context variable *has_permission*, which gets its value from *has_permission()*, indicates whether the user may access the site.
- Foreign key dropdowns now have buttons for changing or deleting related objects using a popup.

`django.contrib.admindocs`

- `reStructuredText` is now parsed in model docstrings.

`django.contrib.auth`

- Authorization backends can now raise *PermissionDenied* in *has_perm()* and *has_module_perms()* to short-circuit permission checking.
- *PasswordResetForm* now has a method *send_mail()* that can be overridden to customize the mail to be sent.
- The *max_length* of *Permission.name* has been increased from 50 to 255 characters. Please run the database migration.
- *USERNAME_FIELD* and *REQUIRED_FIELDS* now supports *ForeignKeys*.

- The default iteration count for the PBKDF2 password hasher has been increased by 33%. This backwards compatible change will not affect users who have subclassed `django.contrib.auth.hashers.PBKDF2PasswordHasher` to change the default value.

`django.contrib.gis`

- A new [GeoJSON serializer](#) is now available.
- It is now allowed to include a subquery as a geographic lookup argument, for example `City.objects.filter(point__within=Country.objects.filter(continent='Africa').values('mpoly'))`.
- The SpatiaLite backend now supports `Collect` and `Extent` aggregates when the database version is 3.0 or later.
- The PostGIS 2 `CREATE EXTENSION postgis` and the SpatiaLite `SELECT InitSpatialMetaData` initialization commands are now automatically run by [migrate](#).
- The GDAL interface now supports retrieving properties of [raster \(image\) data file](#).
- Compatibility shims for `SpatialRefSys` and `GeometryColumns` changed in Django 1.2 have been removed.
- All GDAL-related exceptions are now raised with `GDALException`. The former `OGRException` has been kept for backwards compatibility but should not be used any longer.

`django.contrib.sessions`

- Session cookie is now deleted after [flush\(\)](#) is called.

`django.contrib.sitemaps`

- The new [Sitemap.i18n](#) attribute allows you to generate a sitemap based on the [LANGUAGES](#) setting.

`django.contrib.sites`

- [get_current_site\(\)](#) will now lookup the current site based on [request.get_host\(\)](#) if the `SITE_ID` setting is not defined.
- The default [Site](#) created when running `migrate` now respects the `SITE_ID` setting (instead of always using `pk=1`).

Cache

- The `incr()` method of the `django.core.cache.backends.locmem.LocMemCache` backend is now thread-safe.

Cryptography

- The `max_age` parameter of the `django.core.signing.TimestampSigner.unsign()` method now also accepts a `datetime.timedelta` object.

Database backends

- The MySQL backend no longer strips microseconds from `datetime` values as MySQL 5.6.4 and up supports fractional seconds depending on the declaration of the datetime field (when `DATETIME` includes fractional precision greater than 0). New datetime database columns created with Django 1.8 and MySQL 5.6.4 and up will support microseconds. See the [MySQL database notes](#) for more details.
- The MySQL backend no longer creates explicit indexes for foreign keys when using the InnoDB storage engine, as MySQL already creates them automatically.
- The Oracle backend no longer defines the `connection_persists_old_columns` feature as `True`. Instead, Oracle will now include a cache busting clause when getting the description of a table.

Email

- [Email backends](#) now support the context manager protocol for opening and closing connections.
- The SMTP email backend now supports `keyfile` and `certfile` authentication with the `EMAIL_SSL_CERTFILE` and `EMAIL_SSL_KEYFILE` settings.
- The SMTP *EmailBackend* now supports setting the `timeout` parameter with the `EMAIL_TIMEOUT` setting.
- *EmailMessage* and *EmailMultiAlternatives* now support the `reply_to` parameter.

File Storage

- *Storage.get_available_name()* and *Storage.save()* now take a `max_length` argument to implement storage-level maximum filename length constraints. Filenames exceeding this argument will get truncated. This prevents a database error when appending a unique suffix to a long filename that already exists on the storage. See the [deprecation note](#) about adding this argument to your custom storage classes.

Forms

- Form widgets now render attributes with a value of `True` or `False` as HTML5 boolean attributes.
- The new `has_error()` method allows checking if a specific error has happened.
- If `required_css_class` is defined on a form, then the `<label>` tags for required fields will have this class present in its attributes.
- The rendering of non-field errors in unordered lists (`<ul>`) now includes `nonfield` in its list of classes to distinguish them from field-specific errors.
- `Field` now accepts a `label_suffix` argument, which will override the form's `label_suffix`. This enables customizing the suffix on a per-field basis —previously it wasn't possible to override a form's `label_suffix` while using shortcuts such as `{{ form.as_p }}` in templates.
- `SelectDateWidget` now accepts an `empty_label` argument, which will override the top list choice label when `DateField` is not required.
- After an `ImageField` has been cleaned and validated, the `UploadedFile` object will have an additional `image` attribute containing the Pillow `Image` instance used to check if the file was a valid image. It will also update `UploadedFile.content_type` with the image's content type as determined by Pillow.
- You can now pass a callable that returns an iterable of choices when instantiating a `ChoiceField`.

Generic Views

- Generic views that use `MultipleObjectMixin` may now specify the ordering applied to the `queryset` by setting `ordering` or overriding `get_ordering()`.
- The new `SingleObjectMixin.query_pk_and_slug` attribute allows changing the behavior of `get_object()` so that it'll perform its lookup using both the primary key and the slug.
- The `get_form()` method doesn't require a `form_class` to be provided anymore. If not provided `form_class` defaults to `get_form_class()`.
- Placeholders in `ModelFormMixin.success_url` now support the Python `str.format()` syntax. The legacy `%(<foo>)`s syntax is still supported but will be removed in Django 1.10.

Internationalization

- `FORMAT_MODULE_PATH` can now be a list of strings representing module paths. This allows importing several format modules from different reusable apps. It also allows overriding those custom formats in your main Django project.

Logging

- The `django.utils.log.AdminEmailHandler` class now has a `send_mail()` method to make it more subclass friendly.

Management Commands

- Database connections are now always closed after a management command called from the command line has finished doing its job.
- Commands from alternate package formats like eggs are now also discovered.
- The new `dumpdata --output` option allows specifying a file to which the serialized data is written.
- The new `makemessages --exclude` and `compilemessages --exclude` options allow excluding specific locales from processing.
- `compilemessages` now has a `--use-fuzzy` or `-f` option which includes fuzzy translations into compiled files.
- The `loaddata --ignorenonexistent` option now ignores data for models that no longer exist.
- `runserver` now uses daemon threads for faster reloading.
- `inspectdb` now outputs `Meta.unique_together`. It is also able to introspect `AutoField` for MySQL and PostgreSQL databases.
- When calling management commands with options using `call_command()`, the option name can match the command line option name (without the initial dashes) or the final option destination variable name, but in either case, the resulting option received by the command is now always the `dest` name specified in the command option definition (as long as the command uses the `argparse` module).
- The `dbshell` command now supports MySQL's optional SSL certificate authority setting (`--ssl-ca`).
- The new `makemigrations --name` allows giving the migration(s) a custom name instead of a generated one.
- The `loaddata` command now prevents repeated fixture loading. If `FIXTURE_DIRS` contains duplicates or a default fixture directory path (`app_name/fixtures`), an exception is raised.
- The new `makemigrations --exit` option allows exiting with an error code if no migrations are created.
- The new `showmigrations` command allows listing all migrations and their dependencies in a project.

Middleware

- The `CommonMiddleware.response_redirect_class` attribute allows you to customize the redirects issued by the middleware.
- A debug message will be logged to the `django.request` logger when a middleware raises a `MiddlewareNotUsed` exception in `DEBUG` mode.

Migrations

- The `RunSQL` operation can now handle parameters passed to the SQL statements.
- It is now possible to have migrations (most probably [data migrations](#)) for applications without models.
- Migrations can now [serialize model managers](#) as part of the model state.
- A generic mechanism to handle the deprecation of model fields was added.
- The `RunPython.noop()` and `RunSQL.noop` class method/attribute were added to ease in making `RunPython` and `RunSQL` operations reversible.
- The migration operations `RunPython` and `RunSQL` now call the `allow_migrate()` method of database routers. The router can use the newly introduced `app_label` and `hints` arguments to make a routing decision. To take advantage of this feature you need to update the router to the new `allow_migrate` signature, see the [deprecation section](#) for more details.

Models

- Django now logs at most 9000 queries in `connections.queries`, in order to prevent excessive memory usage in long-running processes in debug mode.
- There is now a model `Meta` option to define a `default_related_name` for all relational fields of a model.
- Pickling models and querysets across different versions of Django isn't officially supported (it may work, but there's no guarantee). An extra variable that specifies the current Django version is now added to the pickled state of models and querysets, and Django raises a `RuntimeWarning` when these objects are unpickled in a different version than the one in which they were pickled.
- Added `Model.from_db()` which Django uses whenever objects are loaded using the ORM. The method allows customizing model loading behavior.
- `extra(select={...})` now allows you to escape a literal `%s` sequence using `%%s`.
- [Custom Lookups](#) can now be registered using a decorator pattern.
- The new `Transform.bilateral` attribute allows creating bilateral transformations. These transformations are applied to both `lhs` and `rhs` when used in a lookup expression, providing opportunities for more sophisticated lookups.

- SQL special characters (, %, _) are now escaped properly when a pattern lookup (e.g. `contains`, `startswith`, etc.) is used with an `F()` expression as the right-hand side. In those cases, the escaping is performed by the database, which can lead to somewhat complex queries involving nested `REPLACE` function calls.
- You can now refresh model instances by using `Model.refresh_from_db()`.
- You can now get the set of deferred fields for a model using `Model.get_deferred_fields()`.
- Model field `default`'s are now used when primary key field's are set to `None`.

Signals

- Exceptions from the (receiver, exception) tuples returned by `Signal.send_robust()` now have their traceback attached as a `__traceback__` attribute.
- The `environ` argument, which contains the WSGI environment structure from the request, was added to the `request_started` signal.
- You can now import the `setting_changed()` signal from `django.core.signals` to avoid loading `django.test` in non-test situations. Django no longer does so itself.

System Check Framework

- `register` can now be used as a function.

Templates

- `urlize` now supports domain-only links that include characters after the top-level domain (e.g. `djangoproject.com/` and `djangoproject.com/download/`).
- `urlize` doesn't treat exclamation marks at the end of a domain or its query string as part of the URL (the URL in e.g. `'djangoproject.com!' is djangoproject.com`)
- Added a `locmem.Loader` class that loads Django templates from a Python dictionary.
- The `now` tag can now store its output in a context variable with the usual syntax: `{% now 'j n Y' as varname %}`.

Requests and Responses

- `WSGIRequest` now respects paths starting with `//`.
- The `HttpRequest.build_absolute_uri()` method now handles paths starting with `//` correctly.
- If `DEBUG` is `True` and a request raises a `SuspiciousOperation`, the response will be rendered with a detailed error page.
- The `query_string` argument of `QueryDict` is now optional, defaulting to `None`, so a blank `QueryDict` can now be instantiated with `QueryDict()` instead of `QueryDict(None)` or `QueryDict('')`.
- The `GET` and `POST` attributes of an `HttpRequest` object are now `QueryDicts` rather than dictionaries, and the `FILES` attribute is now a `MultiValueDict`. This brings this class into line with the documentation and with `WSGIRequest`.
- The `HttpResponse.charset` attribute was added.
- `WSGIRequestHandler` now follows RFC in converting URI to IRI, using `uri_to_iri()`.
- The `HttpRequest.get_full_path()` method now escapes unsafe characters from the path portion of a Uniform Resource Identifier (URI) properly.
- `HttpResponse` now implements a few additional methods like `getvalue()` so that instances can be used as stream objects.
- The new `HttpResponse.setdefault()` method allows setting a header unless it has already been set.
- You can use the new `FileResponse` to stream files.
- The `condition()` decorator for conditional view processing now supports the `If-unmodified-since` header.

Tests

- The `RequestFactory.trace()` and `Client.trace()` methods were implemented, allowing you to create TRACE requests in your tests.
- The `count` argument was added to `assertTemplateUsed()`. This allows you to assert that a template was rendered a specific number of times.
- The new `assertJSONNotEqual()` assertion allows you to test that two JSON fragments are not equal.
- Added options to the `test` command to preserve the test database (`--keepdb`), to run the test cases in reverse order (`--reverse`), and to enable SQL logging for failing tests (`--debug-sql`).
- Added the `resolver_match` attribute to test client responses.
- Added several settings that allow customization of test tablespace parameters for Oracle: `DATAFILE`, `DATAFILE_TMP`, `DATAFILE_MAXSIZE` and `DATAFILE_TMP_MAXSIZE`.
- The `override_settings()` decorator can now affect the master router in `DATABASE_ROUTERS`.

- Added test client support for file uploads with file-like objects.
- A shared cache is now used when testing with an SQLite in-memory database when using Python 3.4+ and SQLite 3.7.13+. This allows sharing the database between threads.

Validators

- `URLValidator` now supports IPv6 addresses, Unicode domains, and URLs containing authentication data.

Backwards incompatible changes in 1.8

Warning: In addition to the changes outlined in this section, be sure to review the [deprecation plan](#) for any features that have been removed. If you haven't updated your code within the deprecation timeline for a given feature, its removal may appear as a backwards incompatible change.

Related object operations are run in a transaction

Some operations on related objects such as `add()` or direct assignment ran multiple data modifying queries without wrapping them in transactions. To reduce the risk of data corruption, all data modifying methods that affect multiple related objects (i.e. `add()`, `remove()`, `clear()`, and direct assignment) now perform their data modifying queries from within a transaction, provided your database supports transactions.

This has one backwards incompatible side effect, signal handlers triggered from these methods are now executed within the method's transaction and any exception in a signal handler will prevent the whole operation.

Assigning unsaved objects to relations raises an error

Note: To more easily allow in-memory usage of models, this change was reverted in Django 1.8.4 and replaced with a check during `model.save()`. For example:

```
>>> book = Book.objects.create(name="Django")
>>> book.author = Author(name="John")
>>> book.save()
Traceback (most recent call last):
...
ValueError: save() prohibited to prevent data loss due to unsaved related object 'author'.
```

A similar check on assignment to reverse one-to-one relations was removed in Django 1.8.5.

Assigning unsaved objects to a *ForeignKey*, *GenericForeignKey*, and *OneToOneField* now raises a *ValueError*.

Previously, the assignment of an unsaved object would be silently ignored. For example:

```
>>> book = Book.objects.create(name="Django")
>>> book.author = Author(name="John")
>>> book.author.save()
>>> book.save()

>>> Book.objects.get(name="Django")
>>> book.author
>>>
```

Now, an error will be raised to prevent data loss:

```
>>> book.author = Author(name="john")
Traceback (most recent call last):
...
ValueError: Cannot assign "<Author: John>": "Author" instance isn't saved in the database.
```

If you require allowing the assignment of unsaved instances (the old behavior) and aren't concerned about the data loss possibility (e.g. you never save the objects to the database), you can disable this check by using the `ForeignKey.allow_unsaved_instance_assignment` attribute. (This attribute was removed in 1.8.4 as it's no longer relevant.)

Management commands that only accept positional arguments

If you have written a custom management command that only accepts positional arguments and you didn't specify the `args` command variable, you might get an error like `Error: unrecognized arguments: ...`, as variable parsing is now based on `argparse` which doesn't implicitly accept positional arguments. You can make your command backwards compatible by simply setting the `args` class variable. However, if you don't have to keep compatibility with older Django versions, it's better to implement the new `add_arguments()` method as described in [How to create custom django-admin commands](#).

Custom test management command arguments through test runner

The method to add custom arguments to the `test` management command through the test runner has changed. Previously, you could provide an `option_list` class variable on the test runner to add more arguments (à la `optparse`). Now to implement the same behavior, you have to create an `add_arguments(cls, parser)` class method on the test runner and call `parser.add_argument` to add any custom arguments, as `parser` is now an `argparse.ArgumentParser` instance.

Model check ensures auto-generated column names are within limits specified by database

A field name that's longer than the column name length supported by a database can create problems. For example, with MySQL you'll get an exception trying to create the column, and with PostgreSQL the column name is truncated by the database (you may see a warning in the PostgreSQL logs).

A model check has been introduced to better alert users to this scenario before the actual creation of database tables.

If you have an existing model where this check seems to be a false positive, for example on PostgreSQL where the name was already being truncated, simply use `db_column` to specify the name that's being used.

The check also applies to the columns generated in an implicit `ManyToManyField.through` model. If you run into an issue there, use `through` to create an explicit model and then specify `db_column` on its column(s) as needed.

Query relation lookups now check object types

Querying for model lookups now checks if the object passed is of correct type and raises a `ValueError` if not. Previously, Django didn't care if the object was of correct type; it just used the object's related field attribute (e.g. `id`) for the lookup. Now, an error is raised to prevent incorrect lookups:

```
>>> book = Book.objects.create(name="Django")
>>> book = Book.objects.filter(author=book)
Traceback (most recent call last):
...
ValueError: Cannot query "<Book: Django>": Must be "Author" instance.
```

`select_related()` now checks given fields

`select_related()` now validates that the given fields actually exist. Previously, nonexistent fields were silently ignored. Now, an error is raised:

```
>>> book = Book.objects.select_related("nonexistent_field")
Traceback (most recent call last):
...
FieldError: Invalid field name(s) given in select_related: 'nonexistent_field'
```

The validation also makes sure that the given field is relational:

```
>>> book = Book.objects.select_related("name")
Traceback (most recent call last):
...
FieldError: Non-relational field given in select_related: 'name'
```

Default `EmailField.max_length` increased to 254

The old default 75 character `max_length` was not capable of storing all possible RFC3696/5321-compliant email addresses. In order to store all possible valid email addresses, the `max_length` has been increased to 254 characters. You will need to generate and apply database migrations for your affected models (or add `max_length=75` if you wish to keep the length on your current fields). A migration for `django.contrib.auth.models.User.email` is included.

Support for PostgreSQL versions older than 9.0

The end of upstream support periods was reached in July 2014 for PostgreSQL 8.4. As a consequence, Django 1.8 sets 9.0 as the minimum PostgreSQL version it officially supports.

This also includes dropping support for PostGIS 1.3 and 1.4 as these versions are not supported on versions of PostgreSQL later than 8.4.

Django also now requires the use of Psycopg2 version 2.4.5 or higher (or 2.5+ if you want to use `django.contrib.postgres`).

Support for MySQL versions older than 5.5

The end of upstream support periods was reached in January 2012 for MySQL 5.0 and December 2013 for MySQL 5.1. As a consequence, Django 1.8 sets 5.5 as the minimum MySQL version it officially supports.

Support for Oracle versions older than 11.1

The end of upstream support periods was reached in July 2010 for Oracle 9.2, January 2012 for Oracle 10.1, and July 2013 for Oracle 10.2. As a consequence, Django 1.8 sets 11.1 as the minimum Oracle version it officially supports.

Specific privileges used instead of roles for tests on Oracle

Earlier versions of Django granted the `CONNECT` and `RESOURCE` roles to the test user on Oracle. These roles have been deprecated, so Django 1.8 uses the specific underlying privileges instead. This changes the privileges required of the main user for running tests (unless the project is configured to avoid creating a test user). The exact privileges required now are detailed in [Oracle notes](#).

`AbstractUser.last_login` allows null values

The `AbstractUser.last_login` field now allows null values. Previously, it defaulted to the time when the user was created which was misleading if the user never logged in. If you are using the default user (`django.contrib.auth.models.User`), run the database migration included in `contrib.auth`.

If you are using a custom user model that inherits from `AbstractUser`, you'll need to run `makemigrations` and generate a migration for your app that contains that model. Also, if wish to set `last_login` to `NULL` for users who haven't logged in, you can run this query:

```
from django.db import models
from django.contrib.auth import get_user_model
from django.contrib.auth.models import AbstractBaseUser

UserModel = get_user_model()
if issubclass(UserModel, AbstractBaseUser):
    UserModel._default_manager.filter(last_login=models.F("date_joined")).update(
        last_login=None
    )
```

`django.contrib.gis`

- Support for GEOS 3.1 and GDAL 1.6 has been dropped.
- Support for SpatiaLite < 2.4 has been dropped.
- GIS-specific lookups have been refactored to use the `django.db.models.Lookup` API.
- The default `str` representation of `GEOSGeometry` objects has been changed from WKT to EWKT format (including the SRID). As this representation is used in the serialization framework, that means that `dumpdata` output will now contain the SRID value of geometry objects.

Priority of context processors for `TemplateResponse` brought in line with `render`

The `TemplateResponse` constructor is designed to be a drop-in replacement for the `render()` function. However, it had a slight incompatibility, in that for `TemplateResponse`, context data from the passed in context dictionary could be shadowed by context data returned from context processors, whereas for `render` it was the other way around. This was a bug, and the behavior of `render` is more appropriate, since it allows the globally defined context processors to be overridden locally in the view. If you were relying on the fact context data in a `TemplateResponse` could be overridden using a context processor, you will need to change your code.

Overriding `setUpClass` / `tearDownClass` in test cases

The decorators `override_settings()` and `modify_settings()` now act at the class level when used as class decorators. As a consequence, when overriding `setUpClass()` or `tearDownClass()`, the `super` implementation should always be called.

Removal of `django.contrib.formtools`

The `formtools` contrib app has been moved to a separate package and the relevant documentation pages have been updated or removed.

The new package is available [on GitHub](#) and on PyPI.

Database connection reloading between tests

Django previously closed database connections between each test within a `TestCase`. This is no longer the case as Django now wraps the whole `TestCase` within a transaction. If some of your tests relied on the old behavior, you should have them inherit from `TransactionTestCase` instead.

Cleanup of the `django.template` namespace

If you've been relying on private APIs exposed in the `django.template` module, you may have to import them from `django.template.base` instead.

Also private APIs `django.template.base.compile_string()`, `django.template.loader.find_template()`, and `django.template.loader.get_template_from_string()` were removed.

model attribute on private model relations

In earlier versions of Django, on a model with a reverse foreign key relationship (for example), `model._meta.get_all_related_objects()` returned the relationship as a `django.db.models.related.RelatedObject` with the `model` attribute set to the source of the relationship. Now, this method returns the relationship as `django.db.models.fields.related.ManyToOneRel` (private API `RelatedObject` has been removed), and the `model` attribute is set to the target of the relationship instead of the source. The source model is accessible on the `related_model` attribute instead.

Consider this example from the tutorial in Django 1.8:

```
>>> p = Poll.objects.get(pk=1)
>>> p._meta.get_all_related_objects()
[<ManyToOneRel: polls.choice>]
>>> p._meta.get_all_related_objects()[0].model
```

(continues on next page)

(continued from previous page)

```
<class 'polls.models.Poll'>
>>> p._meta.get_all_related_objects()[0].related_model
<class 'polls.models.Choice'>
```

and compare it to the behavior on older versions:

```
>>> p._meta.get_all_related_objects()
[<RelatedObject: polls:choice related to poll>]
>>> p._meta.get_all_related_objects()[0].model
<class 'polls.models.Choice'>
```

To access the source model, you can use a pattern like this to write code that will work with both Django 1.8 and older versions:

```
for relation in opts.get_all_related_objects():
    to_model = getattr(relation, "related_model", relation.model)
```

Also note that `get_all_related_objects()` is deprecated in 1.8.

Database backend API

The following changes to the database backend API are documented to assist those writing third-party backends in updating their code:

- `BaseDatabaseXXX` classes have been moved to `django.db.backends.base`. Please import them from the new locations:

```
from django.db.backends.base.base import BaseDatabaseWrapper
from django.db.backends.base.client import BaseDatabaseClient
from django.db.backends.base.creation import BaseDatabaseCreation
from django.db.backends.base.features import BaseDatabaseFeatures
from django.db.backends.base.introspection import BaseDatabaseIntrospection
from django.db.backends.base.introspection import FieldInfo, TableInfo
from django.db.backends.base.operations import BaseDatabaseOperations
from django.db.backends.base.schema import BaseDatabaseSchemaEditor
from django.db.backends.base.validation import BaseDatabaseValidation
```

- The `data_types`, `data_types_suffix`, and `data_type_check_constraints` attributes have moved from the `DatabaseCreation` class to `DatabaseWrapper`.
- The `SQLCompiler.as_sql()` method now takes a subquery parameter ([#24164](#)).
- The `BaseDatabaseOperations.date_interval_sql()` method now only takes a `timedelta` parameter.

`django.contrib.admin`

- `AdminSite` no longer takes an `app_name` argument and its `app_name` attribute has been removed. The application name is always `admin` (as opposed to the instance name which you can still customize using `AdminSite(name="...")`).
- The `ModelAdmin.get_object()` method (private API) now takes a third argument named `from_field` in order to specify which field should match the provided `object_id`.
- The `ModelAdmin.response_delete()` method now takes a second argument named `obj_id` which is the serialized identifier used to retrieve the object before deletion.

Default autoescaping of functions in `django.template.defaultfilters`

In order to make built-in template filters that output HTML “safe by default” when calling them in Python code, the following functions in `django.template.defaultfilters` have been changed to automatically escape their input value:

- `join`
- `linebreaksbr`
- `linebreaks_filter`
- `linenumbers`
- `unordered_list`
- `urlize`
- `urlizetrunc`

You can revert to the old behavior by specifying `autoescape=False` if you are passing trusted content. This change doesn't have any effect when using the corresponding filters in templates.

Miscellaneous

- `connections.queries` is now a read-only attribute.
- Database connections are considered equal only if they're the same object. They aren't hashable any more.
- `GZipMiddleware` used to disable compression for some content types when the request is from Internet Explorer, in order to work around a bug in IE6 and earlier. This behavior could affect performance on IE7 and later. It was removed.
- `URLField.to_python` no longer adds a trailing slash to pathless URLs.
- The `length` template filter now returns 0 for an undefined variable, rather than an empty string.

- `ForeignKey.default_error_message['invalid']` has been changed from `'%(model)s instance with pk %(pk)r does not exist.'` to `'%(model)s instance with %(field)s %(value)r does not exist.'` If you are using this message in your own code, please update the list of interpolated parameters. Internally, Django will continue to provide the `pk` parameter in `params` for backwards compatibility.
- `UserCreationForm.error_messages['duplicate_username']` is no longer used. If you wish to customize that error message, [override it on the form](#) using the `'unique'` key in `Meta.error_messages['username']` or, if you have a custom form field for `'username'`, using the `'unique'` key in its `error_messages` argument.
- The block `usertools` in the `base.html` template of `django.contrib.admin` now requires the `has_permission` context variable to be set. If you have any custom admin views that use this template, update them to pass `AdminSite.has_permission()` as this new variable's value or simply include `AdminSite.each_context(request)` in the context.
- Internal changes were made to the `ClearableFileInput` widget to allow more customization. The undocumented `url_markup_template` attribute was removed in favor of `template_with_initial`.
- For consistency with other major vendors, the `en_GB` locale now has Monday as the first day of the week.
- Seconds have been removed from any locales that had them in `TIME_FORMAT`, `DATETIME_FORMAT`, or `SHORT_DATETIME_FORMAT`.
- The default max size of the Oracle test tablespace has increased from 300M (or 200M, before 1.7.2) to 500M.
- `reverse()` and `reverse_lazy()` now return Unicode strings instead of bytestrings.
- The `CacheClass` shim has been removed from all cache backends. These aliases were provided for backwards compatibility with Django 1.3. If you are still using them, please update your project to use the real class name found in the `BACKEND` key of the `CACHES` setting.
- By default, `call_command()` now always skips the check framework (unless you pass it `skip_checks=False`).
- When iterating over lines, `File` now uses [universal newlines](#). The following are recognized as ending a line: the Unix end-of-line convention `'\n'`, the Windows convention `'\r\n'`, and the old Macintosh convention `'\r'`.
- The Memcached cache backends `MemcachedCache` and `PyLibMCCache` will delete a key if `set()` fails. This is necessary to ensure the `cache_db` session store always fetches the most current session data.
- Private APIs `override_template_loaders` and `override_with_test_loader` in `django.test.utils` were removed. Override `TEMPLATES` with `override_settings` instead.
- Warnings from the MySQL database backend are no longer converted to exceptions when `DEBUG` is `True`.

- `HttpRequest` now has a simplified `repr` (e.g. `<WSGIRequest: GET '/somepath/'>`). This won't change the behavior of the `SafeExceptionReporterFilter` class.
- Class-based views that use `ModelFormMixin` will raise an `ImproperlyConfigured` exception when both the `fields` and `form_class` attributes are specified. Previously, `fields` was silently ignored.
- When following redirects, the test client now raises `RedirectCycleError` if it detects a loop or hits a maximum redirect limit (rather than passing silently).
- Translatable strings set as the `default` parameter of the field are cast to concrete strings later, so the return type of `Field.get_default()` is different in some cases. There is no change to default values which are the result of a callable.
- `GenericIPAddressField.empty_strings_allowed` is now `False`. Database backends that interpret empty strings as null (only Oracle among the backends that Django includes) will no longer convert null values back to an empty string. This is consistent with other backends.
- When the `BaseCommand.leave_locale_alone` attribute is `False`, translations are now deactivated instead of forcing the “en-us” locale. In the case your models contained non-English strings and you counted on English translations to be activated in management commands, this will not happen any longer. It might be that new database migrations are generated (once) after migrating to 1.8.
- `django.utils.translation.get_language()` now returns `None` instead of `LANGUAGE_CODE` when translations are temporarily deactivated.
- When a translation doesn't exist for a specific literal, the fallback is now taken from the `LANGUAGE_CODE` language (instead of from the untranslated msgid message).
- The `name` field of `django.contrib.contenttypes.models.ContentType` has been removed by a migration and replaced by a property. That means it's not possible to query or filter a `ContentType` by this field any longer.

Be careful if you upgrade to Django 1.8 and skip Django 1.7. If you run `manage.py migrate --fake`, this migration will be skipped and you'll see a `RuntimeError: Error creating new content types.` exception because the `name` column won't be dropped from the database. Use `manage.py migrate --fake-initial` to fake only the initial migration instead.

- The new `migrate --fake-initial` option allows faking initial migrations. In 1.7, initial migrations were always automatically faked if all tables created in an initial migration already existed.
- An app without migrations with a `ForeignKey` to an app with migrations may now result in a foreign key constraint error when migrating the database or running tests. In Django 1.7, this could fail silently and result in a missing constraint. To resolve the error, add migrations to the app without them.

Features deprecated in 1.8

Selected methods in `django.db.models.options.Options`

As part of the formalization of the `Model._meta` API (from the `django.db.models.options.Options` class), a number of methods have been deprecated and will be removed in Django 1.10:

- `get_all_field_names()`
- `get_all_related_objects()`
- `get_all_related_objects_with_model()`
- `get_all_related_many_to_many_objects()`
- `get_all_related_m2m_objects_with_model()`
- `get_concrete_fields_with_model()`
- `get_field_by_name()`
- `get_fields_with_model()`
- `get_m2m_with_model()`

Loading `cycle` and `firstof` template tags from future library

Django 1.6 introduced `{% load cycle from future %}` and `{% load firstof from future %}` syntax for forward compatibility of the `cycle` and `firstof` template tags. This syntax is now deprecated and will be removed in Django 1.10. You can simply remove the `{% load ... from future %}` tags.

`django.conf.urls.patterns()`

In the olden days of Django, it was encouraged to reference views as strings in `urlpatterns`:

```
urlpatterns = patterns(
    "",
    url("'^$', "myapp.views.myview"),
)
```

and Django would magically import `myapp.views.myview` internally and turn the string into a real function reference. In order to reduce repetition when referencing many views from the same module, the `patterns()` function takes a required initial `prefix` argument which is prepended to all views-as-strings in that set of `urlpatterns`:

```
urlpatterns = patterns(
    "myapp.views",
    url("^$", "myview"),
    url("^other/$", "otherview"),
)
```

In the modern era, we have updated the tutorial to instead recommend importing your views module and referencing your view functions (or classes) directly. This has a number of advantages, all deriving from the fact that we are using normal Python in place of “Django String Magic” : the errors when you mistype a view name are less obscure, IDEs can help with autocompletion of view names, etc.

So these days, the above use of the `prefix` arg is much more likely to be written (and is better written) as:

```
from myapp import views

urlpatterns = patterns(
    "",
    url("^$", views.myview),
    url("^other/$", views.otherview),
)
```

Thus `patterns()` serves little purpose and is a burden when teaching new users (answering the newbie’s question “why do I need this empty string as the first argument to `patterns()`?”). For these reasons, we are deprecating it. Updating your code is as simple as ensuring that `urlpatterns` is a list of `django.conf.urls.url()` instances. For example:

```
from django.conf.urls import url
from myapp import views

urlpatterns = [
    url("^$", views.myview),
    url("^other/$", views.otherview),
]
```

Passing a string as view to `django.conf.urls.url()`

Related to the previous item, referencing views as strings in the `url()` function is deprecated. Pass the callable view as described in the previous section instead.

Template-related settings

As a consequence of the multiple template engines refactor, several settings are deprecated in favor of *TEMPLATES*:

- `ALLOWED_INCLUDE_ROOTS`
- `TEMPLATE_CONTEXT_PROCESSORS`
- `TEMPLATE_DEBUG`
- `TEMPLATE_DIRS`
- `TEMPLATE_LOADERS`
- `TEMPLATE_STRING_IF_INVALID`

`django.core.context_processors`

Built-in template context processors have been moved to `django.template.context_processors`.

`django.test.SimpleTestCase.urls`

The attribute `SimpleTestCase.urls` for specifying `URLconf` configuration in tests has been deprecated and will be removed in Django 1.10. Use `@override_settings(ROOT_URLCONF=...)` instead.

prefix argument to `i18n_patterns()`

Related to the previous item, the `prefix` argument to `django.conf.urls.i18n.i18n_patterns()` has been deprecated. Simply pass a list of `django.conf.urls.url()` instances instead.

Using an incorrect count of unpacked values in the `for` template tag

Using an incorrect count of unpacked values in `for` tag will raise an exception rather than fail silently in Django 1.10.

Passing a dotted path to `reverse()` and `url`

Reversing URLs by Python path is an expensive operation as it causes the path being reversed to be imported. This behavior has also resulted in a [security issue](#). Use [named URL patterns](#) for reversing instead.

If you are using `django.contrib.sitemaps`, add the `name` argument to the `url` that references `django.contrib.sitemaps.views.sitemap()`:

```
from django.contrib.sitemaps.views import sitemap

url(
    r"^sitemap\.xml$",
    sitemap,
    {"sitemaps": sitemaps},
    name="django.contrib.sitemaps.views.sitemap",
)
```

to ensure compatibility when reversing by Python path is removed in Django 1.10.

Similarly for GIS sitemaps, add `name='django.contrib.gis.sitemaps.views.kml'` or `name='django.contrib.gis.sitemaps.views.kmz'`.

If you are using a Python path for the `LOGIN_URL` or `LOGIN_REDIRECT_URL` setting, use the name of the `url()` instead.

Aggregate methods and modules

The `django.db.models.sql.aggregates` and `django.contrib.gis.db.models.sql.aggregates` modules (both private API), have been deprecated as `django.db.models.aggregates` and `django.contrib.gis.db.models.aggregates` are now also responsible for SQL generation. The old modules will be removed in Django 1.10.

If you were using the old modules, see [Query Expressions](#) for instructions on rewriting custom aggregates using the new stable API.

The following methods and properties of `django.db.models.sql.query.Query` have also been deprecated and the backwards compatibility shims will be removed in Django 1.10:

- `Query.aggregates`, replaced by `annotations`.
- `Query.aggregate_select`, replaced by `annotation_select`.
- `Query.add_aggregate()`, replaced by `add_annotation()`.
- `Query.set_aggregate_mask()`, replaced by `set_annotation_mask()`.
- `Query.append_aggregate_mask()`, replaced by `append_annotation_mask()`.

Extending management command arguments through `Command.option_list`

Management commands now use `argparse` instead of `optparse` to parse command-line arguments passed to commands. This also means that the way to add custom arguments to commands has changed: instead of extending the `option_list` class list, you should now override the `add_arguments()` method and add arguments through `argparse.add_argument()`. See [this example](#) for more details.

`django.core.management.NoArgsCommand`

The class `NoArgsCommand` is now deprecated and will be removed in Django 1.10. Use `BaseCommand` instead, which takes no arguments by default.

Listing all migrations in a project

The `--list` option of the `migrate` management command is deprecated and will be removed in Django 1.10. Use `showmigrations` instead.

`cache_choices` option of `ModelChoiceField` and `ModelMultipleChoiceField`

`ModelChoiceField` and `ModelMultipleChoiceField` took an undocumented, untested option `cache_choices`. This cached querysets between multiple renderings of the same Form object. This option is subject to an accelerated deprecation and will be removed in Django 1.9.

`django.template.resolve_variable()`

The function has been informally marked as “Deprecated” for some time. Replace `resolve_variable(path, context)` with `django.template.Variable(path).resolve(context)`.

`django.contrib.webdesign`

It provided the `lorem` template tag which is now included in the built-in tags. Simply remove `'django.contrib.webdesign'` from `INSTALLED_APPS` and `{% load webdesign %}` from your templates.

`error_message` argument to `django.forms.RegexField`

It provided backwards compatibility for pre-1.0 code, but its functionality is redundant. Use `Field.error_messages['invalid']` instead.

Old `unordered_list` syntax

An older (pre-1.0), more restrictive and verbose input format for the `unordered_list` template filter has been deprecated:

```
["States", [[["Kansas", [[["Lawrence", []], ["Topeka", []]]], ["Illinois", []]]]]]
```

Using the new syntax, this becomes:

```
["States", ["Kansas", ["Lawrence", "Topeka"], "Illinois"]]
```

`django.forms.Field._has_changed()`

Rename this method to `has_changed()` by removing the leading underscore. The old name will still work until Django 1.10.

`django.utils.html.remove_tags()` and `removetags` template filter

`django.utils.html.remove_tags()` as well as the template filter `removetags` have been deprecated as they cannot guarantee safe output. Their existence is likely to lead to their use in security-sensitive contexts where they are not actually safe.

The unused and undocumented `django.utils.html.strip_entities()` function has also been deprecated.

`is_admin_site` argument to `django.contrib.auth.views.password_reset()`

It's a legacy option that should no longer be necessary.

SubfieldBase

`django.db.models.fields.subclassing.SubfieldBase` has been deprecated and will be removed in Django 1.10. Historically, it was used to handle fields where type conversion was needed when loading from the database, but it was not used in `.values()` calls or in aggregates. It has been replaced with `from_db_value()`.

The new approach doesn't call the `to_python()` method on assignment as was the case with `SubfieldBase`. If you need that behavior, reimplement the `Creator` class from Django's source code in your project.

`django.utils.checksums`

The `django.utils.checksums` module has been deprecated and will be removed in Django 1.10. The functionality it provided (validating checksum using the Luhn algorithm) was undocumented and not used in Django. The module has been moved to the [django-localflavor](#) package (version 1.1+).

`InlineAdminForm.original_content_type_id`

The `original_content_type_id` attribute on `InlineAdminForm` has been deprecated and will be removed in Django 1.10. Historically, it was used to construct the “view on site” URL. This URL is now accessible using the `absolute_url` attribute of the form.

`django.views.generic.edit.FormMixin.get_form()`’s `form_class` argument

`FormMixin` subclasses that override the `get_form()` method should make sure to provide a default value for the `form_class` argument since it’s now optional.

Rendering templates loaded by `get_template()` with a `Context`

The return type of `get_template()` has changed in Django 1.8: instead of a `django.template.Template`, it returns a `Template` instance whose exact type depends on which backend loaded it.

Both classes provide a `render()` method, however, the former takes a `django.template.Context` as an argument while the latter expects a `dict`. This change is enforced through a deprecation path for Django templates.

All this also applies to `select_template()`.

Template and Context classes in template responses

Some methods of `SimpleTemplateResponse` and `TemplateResponse` accepted `django.template.Context` and `django.template.Template` objects as arguments. They should now receive `dict` and backend-dependent template objects respectively.

This also applies to the return types if you have subclassed either template response class.

Check the [template response API documentation](#) for details.

`current_app` argument of template-related APIs

The following functions and classes will no longer accept a `current_app` parameter to set an URL namespace in Django 1.10:

- `django.shortcuts.render()`
- `django.template.Context()`
- `django.template.RequestContext()`
- `django.template.response.TemplateResponse()`

Set `request.current_app` instead, where `request` is the first argument to these functions or classes. If you're using a plain `Context`, use a `RequestContext` instead.

dictionary and `context_instance` arguments of rendering functions

The following functions will no longer accept the `dictionary` and `context_instance` parameters in Django 1.10:

- `django.shortcuts.render()`
- `django.shortcuts.render_to_response()`
- `django.template.loader.render_to_string()`

Use the `context` parameter instead. When `dictionary` is passed as a positional argument, which is the most common idiom, no changes are needed.

If you're passing a `Context` in `context_instance`, pass a `dict` in the `context` parameter instead. If you're passing a `RequestContext`, pass the request separately in the `request` parameter.

`dirs` argument of template-finding functions

The following functions will no longer accept a `dirs` parameter to override `TEMPLATE_DIRS` in Django 1.10:

- `django.template.loader.get_template()`
- `django.template.loader.select_template()`
- `django.shortcuts.render()`
- `django.shortcuts.render_to_response()`

The parameter didn't work consistently across different template loaders and didn't work for included templates.

`django.template.loader.BaseLoader`

`django.template.loader.BaseLoader` was renamed to `django.template.loaders.base.Loader`. If you've written a custom template loader that inherits `BaseLoader`, you must inherit `Loader` instead.

`django.test.utils.TestTemplateLoader`

Private API `django.test.utils.TestTemplateLoader` is deprecated in favor of `django.template.loaders.locmem.Loader` and will be removed in Django 1.9.

Support for the `max_length` argument on custom Storage classes

Storage subclasses should add `max_length=None` as a parameter to `get_available_name()` and/or `save()` if they override either method. Support for storages that do not accept this argument will be removed in Django 1.10.

`qn` replaced by `compiler`

In previous Django versions, various internal ORM methods (mostly `as_sql` methods) accepted a `qn` (for “quote name”) argument, which was a reference to a function that quoted identifiers for sending to the database. In Django 1.8, that argument has been renamed to `compiler` and is now a full `SQLCompiler` instance. For backwards-compatibility, calling a `SQLCompiler` instance performs the same name-quoting that the `qn` function used to. However, this backwards-compatibility shim is immediately deprecated: you should rename your `qn` arguments to `compiler`, and call `compiler.quote_name_unless_alias(...)` where you previously called `qn(...)`.

Default value of `RedirectView.permanent`

The default value of the `RedirectView.permanent` attribute will change from `True` to `False` in Django 1.9.

Using `AuthenticationMiddleware` without `SessionAuthenticationMiddleware`

`django.contrib.auth.middleware.SessionAuthenticationMiddleware` was added in Django 1.7. In Django 1.7.2, its functionality was moved to `auth.get_user()` and, for backwards compatibility, enabled only if `'django.contrib.auth.middleware.SessionAuthenticationMiddleware'` appears in `MIDDLEWARE_CLASSES`.

In Django 1.10, session verification will be enabled regardless of whether or not `SessionAuthenticationMiddleware` is enabled (at which point `SessionAuthenticationMiddleware` will have no significance). You can add it to your `MIDDLEWARE_CLASSES` sometime before then to opt-in. Please read the [upgrade considerations](#) first.

`django.contrib.sitemaps.FlatPageSitemap`

`django.contrib.sitemaps.FlatPageSitemap` has moved to `django.contrib.flatpages.sitemaps.FlatPageSitemap`. The old import location is deprecated and will be removed in Django 1.9.

Model Field.related

Private attribute `django.db.models.Field.related` is deprecated in favor of `Field.rel`. The latter is an instance of `django.db.models.fields.related.ForeignKeyRel` which replaces `django.db.models.related.RelatedObject`. The `django.db.models.related` module has been removed and the `Field.related` attribute will be removed in Django 1.10.

ssi template tag

The `ssi` template tag allows files to be included in a template by absolute path. This is of limited use in most deployment situations, and the `include` tag often makes more sense. This tag is now deprecated and will be removed in Django 1.10.

= as comparison operator in if template tag

Using a single equals sign with the `{% if %}` template tag for equality testing was undocumented and untested. It's now deprecated in favor of `==`.

%(<foo>)s syntax in ModelFormMixin.success_url

The legacy `%(<foo>)s` syntax in `ModelFormMixin.success_url` is deprecated and will be removed in Django 1.10.

GeoQuerySet aggregate methods

The `collect()`, `extent()`, `extent3d()`, `make_line()`, and `unionagg()` aggregate methods are deprecated and should be replaced by their function-based aggregate equivalents (`Collect`, `Extent`, `Extent3D`, `MakeLine`, and `Union`).

Signature of the `allow_migrate` router method

The signature of the `allow_migrate()` method of database routers has changed from `allow_migrate(db, model)` to `allow_migrate(db, app_label, model_name=None, **hints)`.

When `model_name` is set, the value that was previously given through the `model` positional argument may now be found inside the `hints` dictionary under the key `'model'`.

After switching to the new signature the router will also be called by the *RunPython* and *RunSQL* operations.

Features removed in 1.8

These features have reached the end of their deprecation cycle and are removed in Django 1.8. See [Features deprecated in 1.6](#) for details, including how to remove usage of these features.

- `django.contrib.comments` is removed.
- The following transaction management APIs are removed:
 - `TransactionMiddleware`
 - the decorators and context managers `autocommit`, `commit_on_success`, and `commit_manually`, defined in `django.db.transaction`
 - the functions `commit_unless_managed` and `rollback_unless_managed`, also defined in `django.db.transaction`
 - the `TRANSACTIONS_MANAGED` setting
- The *cycle* and *firstof* template tags auto-escape their arguments.
- The `SEND_BROKEN_LINK_EMAILS` setting is removed.
- `django.middleware.doc.XViewMiddleware` is removed.
- The `Model._meta.module_name` alias is removed.
- The backward compatible shims introduced to rename `get_query_set` and similar query-set methods are removed. This affects the following classes: `BaseModelAdmin`, `ChangeList`, `BaseCommentNode`, `GenericForeignKey`, `Manager`, `SingleRelatedObjectDescriptor` and `ReverseSingleRelatedObjectDescriptor`.
- The backward compatible shims introduced to rename the attributes `ChangeList.root_query_set` and `ChangeList.query_set` are removed.
- `django.views.defaults.shortcut` and `django.conf.urls.shortcut` are removed.
- Support for the Python Imaging Library (PIL) module is removed.
- The following private APIs are removed:
 - `django.db.backend`

- `django.db.close_connection()`
- `django.db.backends.creation.BaseDatabaseCreation.set_autocommit()`
- `django.db.transaction.is_managed()`
- `django.db.transaction.managed()`
- `django.forms.widgets.RadioInput` is removed.
- The module `django.test.simple` and the class `django.test.simple.DjangoTestSuiteRunner` are removed.
- The module `django.test._doctest` is removed.
- The `CACHE_MIDDLEWARE_ANONYMOUS_ONLY` setting is removed. This change affects both `django.middleware.cache.CacheMiddleware` and `django.middleware.cache.UpdateCacheMiddleware` despite the lack of a deprecation warning in the latter class.
- Usage of the hard-coded Hold down “Control” , or “Command” on a Mac, to select more than one string to override or append to user-provided `help_text` in forms for `ManyToMany` model fields is not performed by Django anymore either at the model or forms layer.
- The `Model._meta.get_(add|change|delete)_permission` methods are removed.
- The session key `django_language` is no longer read for backwards compatibility.
- Geographic Sitemaps are removed (`django.contrib.gis.sitemaps.views.index` and `django.contrib.gis.sitemaps.views.sitemap`).
- `django.utils.html.fix_ampersands`, the `fix_ampersands` template filter, and `django.utils.html.clean_html` are removed.

9.1.14 1.7 release

Django 1.7.11 release notes

November 24, 2015

Django 1.7.11 fixes a security issue and a data loss bug in 1.7.10.

Fixed settings leak possibility in date template filter

If an application allows users to specify an unvalidated format for dates and passes this format to the `date` filter, e.g. `{{ last_updated|date:user_date_format }}`, then a malicious user could obtain any secret in the application’s settings by specifying a settings key instead of a date format. e.g. `"SECRET_KEY"` instead of `"j/m/Y"`.

To remedy this, the underlying function used by the `date` template filter, `django.utils.formats.get_format()`, now only allows accessing the date/time formatting settings.

Bugfixes

- Fixed a data loss possibility with *Prefetch* if `to_attr` is set to a `ManyToManyField` (#25693).

Django 1.7.10 release notes

August 18, 2015

Django 1.7.10 fixes a security issue in 1.7.9.

Denial-of-service possibility in `logout()` view by filling session store

Previously, a session could be created when anonymously accessing the `django.contrib.auth.views.logout()` view (provided it wasn't decorated with *`login_required()`* as done in the admin). This could allow an attacker to easily create many new session records by sending repeated requests, potentially filling up the session store or causing other users' session records to be evicted.

The *`SessionMiddleware`* has been modified to no longer create empty session records, including when *`SESSION_SAVE_EVERY_REQUEST`* is active.

Additionally, the `contrib.sessions.backends.base.SessionBase.flush()` and `cache_db.SessionStore.flush()` methods have been modified to avoid creating a new empty session. Maintainers of third-party session backends should check if the same vulnerability is present in their backend and correct it if so.

Django 1.7.9 release notes

July 8, 2015

Django 1.7.9 fixes several security issues and bugs in 1.7.8.

Denial-of-service possibility by filling session store

In previous versions of Django, the session backends created a new empty record in the session storage any time `request.session` was accessed and there was a session key provided in the request cookies that didn't already have a session record. This could allow an attacker to easily create many new session records simply by sending repeated requests with unknown session keys, potentially filling up the session store or causing other users' session records to be evicted.

The built-in session backends now create a session record only if the session is actually modified; empty session records are not created. Thus this potential DoS is now only possible if the site chooses to expose a session-modifying view to anonymous users.

As each built-in session backend was fixed separately (rather than a fix in the core sessions framework), maintainers of third-party session backends should check whether the same vulnerability is present in their backend and correct it if so.

Header injection possibility since validators accept newlines in input

Some of Django's built-in validators (*EmailValidator*, most seriously) didn't prohibit newline characters (due to the usage of `$` instead of `\Z` in the regular expressions). If you use values with newlines in HTTP response or email headers, you can suffer from header injection attacks. Django itself isn't vulnerable because *HttpResponse* and the mail sending utilities in *django.core.mail* prohibit newlines in HTTP and SMTP headers, respectively. While the validators have been fixed in Django, if you're creating HTTP responses or email messages in other ways, it's a good idea to ensure that those methods prohibit newlines as well. You might also want to validate that any existing data in your application doesn't contain unexpected newlines.

validate_ipv4_address(), *validate_slug()*, and *URLValidator* are also affected, however, as of Django 1.6 the *GenericIPAddressField*, *IPAddressField*, *SlugField*, and *URLField* form fields which use these validators all strip the input, so the possibility of newlines entering your data only exists if you are using these validators outside of the form fields.

The undocumented, internally unused *validate_integer()* function is now stricter as it validates using a regular expression instead of simply casting the value using *int()* and checking if an exception was raised.

Bugfixes

- Prevented the loss of `null/not null` column properties during field renaming of MySQL databases (#24817).
- Fixed *SimpleTestCase.assertRaisesMessage()* on Python 2.7.10 (#24903).

Django 1.7.8 release notes

May 1, 2015

Django 1.7.8 fixes:

- Database introspection with SQLite 3.8.9 (released April 8, 2015) (#24637).
- A database table name quoting regression in 1.7.2 (#24605).
- The loss of `null/not null` column properties during field alteration of MySQL databases (#24595).

Django 1.7.7 release notes

March 18, 2015

Django 1.7.7 fixes several bugs and security issues in 1.7.6.

Denial-of-service possibility with `strip_tags()`

Last year `strip_tags()` was changed to work iteratively. The problem is that the size of the input it's processing can increase on each iteration which results in an infinite loop in `strip_tags()`. This issue only affects versions of Python that haven't received a [bugfix in HTMLParser](#); namely Python < 2.7.7 and 3.3.5. Some operating system vendors have also backported the fix for the Python bug into their packages of earlier versions.

To remedy this issue, `strip_tags()` will now return the original input if it detects the length of the string it's processing increases. Remember that absolutely NO guarantee is provided about the results of `strip_tags()` being HTML safe. So NEVER mark safe the result of a `strip_tags()` call without escaping it first, for example with `escape()`.

Mitigated possible XSS attack via user-supplied redirect URLs

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()` and [i18n](#)) to redirect the user to an “on success” URL. The security checks for these redirects (namely `django.utils.http.is_safe_url()`) accepted URLs with leading control characters and so considered URLs like `\x08javascript:... safe`. This issue doesn't affect Django currently, since we only put this URL into the `Location` response header and browsers seem to ignore JavaScript there. Browsers we tested also treat URLs prefixed with control characters such as `%08//example.com` as relative paths so redirection to an unsafe target isn't a problem either.

However, if a developer relies on `is_safe_url()` to provide safe redirect targets and puts such a URL into a link, they could suffer from an XSS attack as some browsers such as Google Chrome ignore control characters at the start of a URL in an anchor `href`.

Bugfixes

- Fixed renaming of classes in migrations where renaming a subclass would cause incorrect state to be recorded for objects that referenced the superclass ([#24354](#)).
- Stopped writing migration files in dry run mode when merging migration conflicts. When `makemigrations --merge` is called with `verbosity=3` the migration file is written to `stdout` ([#24427](#)).

Django 1.7.6 release notes

March 9, 2015

Django 1.7.6 fixes a security issue and several bugs in 1.7.5.

Mitigated an XSS attack via properties in `ModelAdmin.readonly_fields`

The `ModelAdmin.readonly_fields` attribute in the Django admin allows displaying model fields and model attributes. While the former were correctly escaped, the latter were not. Thus untrusted content could be injected into the admin, presenting an exploitation vector for XSS attacks.

In this vulnerability, every model attribute used in `readonly_fields` that is not an actual model field (e.g. a `property`) will fail to be escaped even if that attribute is not marked as safe. In this release, autoescaping is now correctly applied.

Bugfixes

- Fixed crash when coercing `ManyRelatedManager` to a string (#24352).
- Fixed a bug that prevented migrations from adding a foreign key constraint when converting an existing field to a foreign key (#24447).

Django 1.7.5 release notes

February 25, 2015

Django 1.7.5 fixes several bugs in 1.7.4.

Bugfixes

- Reverted a fix that prevented a migration crash when unapplying `contrib.contenttypes`'s or `contrib.auth`'s first migration (#24075) due to severe impact on the test performance (#24251) and problems in multi-database setups (#24298).
- Fixed a regression that prevented custom fields inheriting from `ManyToManyField` from being recognized in migrations (#24236).
- Fixed crash in `contrib.sites` migrations when a default database isn't used (#24332).
- Added the ability to set the isolation level on PostgreSQL with `psycopg2 ≥ 2.4.2` (#24318). It was advertised as a new feature in Django 1.6 but it didn't work in practice.
- Formats for the Azerbaijani locale (`az`) have been added.

Django 1.7.4 release notes

January 27, 2015

Django 1.7.4 fixes several bugs in 1.7.3.

Bugfixes

- Fixed a migration crash when unapplying `contrib.contenttypes`'s or `contrib.auth`'s first migration (#24075).
- Made the migration's `RenameModel` operation rename `ManyToManyField` tables (#24135).
- Fixed a migration crash on MySQL when migrating from a `OneToOneField` to a `ForeignKey` (#24163).
- Prevented the `static.serve` view from producing `ResourceWarnings` in certain circumstances (security fix regression, #24193).
- Fixed schema check for `ManyToManyField` to look for internal type instead of checking class instance, so you can write custom m2m-like fields with the same behavior. (#24104).

Django 1.7.3 release notes

January 13, 2015

Django 1.7.3 fixes several security issues and bugs in 1.7.2.

WSGI header spoofing via underscore/dash conflation

When HTTP headers are placed into the WSGI environ, they are normalized by converting to uppercase, converting all dashes to underscores, and prepending `HTTP_`. For instance, a header `X-Auth-User` would become `HTTP_X_AUTH_USER` in the WSGI environ (and thus also in Django's `request.META` dictionary).

Unfortunately, this means that the WSGI environ cannot distinguish between headers containing dashes and headers containing underscores: `X-Auth-User` and `X-Auth_User` both become `HTTP_X_AUTH_USER`. This means that if a header is used in a security-sensitive way (for instance, passing authentication information along from a front-end proxy), even if the proxy carefully strips any incoming value for `X-Auth-User`, an attacker may be able to provide an `X-Auth_User` header (with underscore) and bypass this protection.

In order to prevent such attacks, both Nginx and Apache 2.4+ strip all headers containing underscores from incoming requests by default. Django's built-in development server now does the same. Django's development server is not recommended for production use, but matching the behavior of common production servers reduces the surface area for behavior changes during deployment.

Mitigated possible XSS attack via user-supplied redirect URLs

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()` and [i18n](#)) to redirect the user to an “on success” URL. The security checks for these redirects (namely `django.utils.http.is_safe_url()`) didn’t strip leading whitespace on the tested URL and as such considered URLs like `\njavascript:... safe`. If a developer relied on `is_safe_url()` to provide safe redirect targets and put such a URL into a link, they could suffer from a XSS attack. This bug doesn’t affect Django currently, since we only put this URL into the `Location` response header and browsers seem to ignore JavaScript there.

Denial-of-service attack against `django.views.static.serve`

In older versions of Django, the `django.views.static.serve()` view read the files it served one line at a time. Therefore, a big file with no newlines would result in memory usage equal to the size of that file. An attacker could exploit this and launch a denial-of-service attack by simultaneously requesting many large files. This view now reads the file in chunks to prevent large memory usage.

Note, however, that this view has always carried a warning that it is not hardened for production use and should be used only as a development aid. Now may be a good time to audit your project and serve your files in production using a real front-end web server if you are not doing so.

Database denial-of-service with `ModelMultipleChoiceField`

Given a form that uses `ModelMultipleChoiceField` and `show_hidden_initial=True` (not a documented API), it was possible for a user to cause an unreasonable number of SQL queries by submitting duplicate values for the field’s data. The validation logic in `ModelMultipleChoiceField` now deduplicates submitted values to address this issue.

Bugfixes

- The default iteration count for the PBKDF2 password hasher has been increased by 25%. This part of the normal major release process was inadvertently omitted in 1.7. This backwards compatible change will not affect users who have subclassed `django.contrib.auth.hashers.PBKDF2PasswordHasher` to change the default value.
- Fixed a crash in the CSRF middleware when handling non-ASCII referer header ([#23815](#)).
- Fixed a crash in the `django.contrib.auth.redirect_to_login` view when passing a `reverse_lazy()` result on Python 3 ([#24097](#)).
- Added correct formats for Greek ([e1](#)) ([#23967](#)).
- Fixed a migration crash when unapplying a migration where multiple operations interact with the same model ([#24110](#)).

Django 1.7.2 release notes

January 2, 2015

Django 1.7.2 fixes several bugs in 1.7.1.

Additionally, Django's vendored version of six, `django.utils.six`, has been upgraded to the latest release (1.9.0).

Bugfixes

- Fixed migration's renaming of auto-created many-to-many tables when changing `Meta.db_table` (#23630).
- Fixed a migration crash when adding an explicit `id` field to a model on SQLite (#23702).
- Added a warning for duplicate models when a module is reloaded. Previously a `RuntimeError` was raised every time two models clashed in the app registry. (#23621).
- Prevented `flush` from loading initial data for migrated apps (#23699).
- Fixed a `makemessages` regression in 1.7.1 when `STATIC_ROOT` has the default `None` value (#23717).
- Added GeoDjango compatibility with `mysqlclient` database driver.
- Fixed MySQL 5.6+ crash with `GeometryFields` in migrations (#23719).
- Fixed a migration crash when removing a field that is referenced in `AlterIndexTogether` or `AlterUniqueTogether` (#23614).
- Updated the first day of the week in the Ukrainian locale to Monday.
- Added support for transactional spatial metadata initialization on `Spatialite` 4.1+ (#23152).
- Fixed a migration crash that prevented changing a nullable field with a default to non-nullable with the same default (#23738).
- Fixed a migration crash when adding `GeometryFields` with `blank=True` on PostGIS (#23731).
- Allowed usage of `DateTimeField()` as `Transform.output_field` (#23420).
- Fixed a migration serializing bug involving `float("nan")` and `float("inf")` (#23770).
- Fixed a regression where custom form fields having a `queryset` attribute but no `limit_choices_to` could not be used in a `ModelForm` (#23795).
- Fixed a custom field type validation error with MySQL backend when `db_type` returned `None` (#23761).
- Fixed a migration crash when a field is renamed that is part of an `index_together` (#23859).
- Fixed `squashmigrations` to respect the `--no-optimize` parameter (#23799).
- Made `RenameModel` reversible (#22248)

- Avoided unnecessary rollbacks of migrations from other apps when migrating backwards (#23410).
- Fixed a rare query error when using deeply nested subqueries (#23605).
- Fixed a crash in migrations when deleting a field that is part of a `index/unique_together` constraint (#23794).
- Fixed `django.core.files.File.__repr__()` when the file's name contains Unicode characters (#23888).
- Added missing context to the admin's `delete_selected` view that prevented custom site header, etc. from appearing (#23898).
- Fixed a regression with dynamically generated inlines and allowed field references in the admin (#23754).
- Fixed an infinite loop bug for certain cyclic migration dependencies, and made the error message for cyclic dependencies much more helpful.
- Added missing `index_together` handling for SQLite (#23880).
- Fixed a crash when RunSQL SQL content was collected by the schema editor, typically when using `sqlmigrate` (#23909).
- Fixed a regression in `contrib.admin` add/change views which caused some `ModelAdmin` methods to receive the incorrect `obj` value (#23934).
- Fixed `runserver` crash when socket error message contained Unicode characters (#23946).
- Fixed serialization of `type` when adding a `deconstruct()` method (#23950).
- Prevented the `django.contrib.auth.middleware.SessionAuthenticationMiddleware` from setting a "Vary: Cookie" header on all responses (#23939).
- Fixed a crash when adding `blank=True` to `TextField()` on MySQL (#23920).
- Fixed index creation by the migration infrastructure, particularly when dealing with PostgreSQL specific `{text|varchar}_pattern_ops` indexes (#23954).
- Fixed bug in `makemigrations` that created broken migration files when dealing with multiple table inheritance and inheriting from more than one model (#23956).
- Fixed a crash when a `MultiValueField` has invalid data (#23674).
- Fixed a crash in the admin when using "Save as new" and also deleting a related inline (#23857).
- Always converted `related_name` to text (Unicode), since that is required on Python 3 for interpolation. Removed conversion of `related_name` to text in migration deconstruction (#23455 and #23982).
- Enlarged the sizes of tablespaces which are created by default for testing on Oracle (the main tablespace was increased from 200M to 300M and the temporary tablespace from 100M to 150M). This was required to accommodate growth in Django's own test suite (#23969).
- Fixed `timesince` filter translations in Korean (#23989).

- Fixed the SQLite `SchemaEditor` to properly add defaults in the absence of a user specified default. For example, a `CharField` with `blank=True` didn't set existing rows to an empty string which resulted in a crash when adding the `NOT NULL` constraint (#23987).
- `makemigrations` no longer prompts for a default value when adding `TextField()` or `CharField()` without a default (#23405).
- Fixed a migration crash when adding `order_with_respect_to` to a table with existing rows (#23983).
- Restored the `pre_migrate` signal if all apps have migrations (#23975).
- Made admin system checks run for custom `AdminSites` (#23497).
- Ensured the app registry is fully populated when unpickling models. When an external script (like a queueing infrastructure) reloads pickled models, it could crash with an `AppRegistryNotReady` exception (#24007).
- Added quoting to field indexes in the SQL generated by migrations to prevent a crash when the index name requires it (#24015).
- Added `datetime.time` support to migrations questioner (#23998).
- Fixed `admindocs` crash on apps installed as eggs (#23525).
- Changed migrations autodetector to generate an `AlterModelOptions` operation instead of `DeleteModel` and `CreateModel` operations when changing `Meta.managed`. This prevents data loss when changing managed from `False` to `True` and vice versa (#24037).
- Enabled the `sqlsequencereset` command on apps with migrations (#24054).
- Added tablespace SQL to apps with migrations (#24051).
- Corrected `contrib.sites` default site creation in a multiple database setup (#24000).
- Restored support for objects that aren't `str` or `bytes` in `django.utils.safestring.mark_for_escaping()` on Python 3.
- Supported strings escaped by third-party libraries with the `__html__` convention in the template engine (#23831).
- Prevented extraneous `DROP DEFAULT` SQL in migrations (#23581).
- Restored the ability to use more than five levels of subqueries (#23758).
- Fixed crash when `ValidationError` is initialized with a `ValidationError` that is initialized with a dictionary (#24008).
- Prevented a crash on apps without migrations when running `migrate --list` (#23366).

Django 1.7.1 release notes

October 22, 2014

Django 1.7.1 fixes several bugs in 1.7.

Bugfixes

- Allowed related many-to-many fields to be referenced in the admin ([#23604](#)).
- Added a more helpful error message if you try to migrate an app without first creating the `contenttypes` table ([#22411](#)).
- Modified migrations dependency algorithm to avoid possible infinite recursion.
- Fixed a `UnicodeDecodeError` when the `flush` error message contained Unicode characters ([#22882](#)).
- Reinstated missing `CHECK SQL` clauses which were omitted on some backends when not using migrations ([#23416](#)).
- Fixed serialization of `type` objects in migrations ([#22951](#)).
- Allowed inline and hidden references to admin fields ([#23431](#)).
- The `@deconstructible` decorator now fails with a `ValueError` if the decorated object cannot automatically be imported ([#23418](#)).
- Fixed a typo in an `inlineformset_factory()` error message that caused a crash ([#23451](#)).
- Restored the ability to use `ABSOLUTE_URL_OVERRIDES` with the `'auth.User'` model ([#11775](#)). As a side effect, the setting now adds a `get_absolute_url()` method to any model that appears in `ABSOLUTE_URL_OVERRIDES` but doesn't define `get_absolute_url()`.
- Avoided masking some `ImportError` exceptions during application loading ([#22920](#)).
- Empty `index_together` or `unique_together` model options no longer results in infinite migrations ([#23452](#)).
- Fixed crash in `contrib.sitemaps` if `lastmod` returned a `date` rather than a `datetime` ([#23403](#)).
- Allowed migrations to work with `app_labels` that have the same last part (e.g. `django.contrib.auth` and `vendor.auth`) ([#23483](#)).
- Restored the ability to deepcopy `F` objects ([#23492](#)).
- Formats for Welsh (`cy`) and several Chinese locales (`zh_CN`, `zh_Hans`, `zh_Hant` and `zh_TW`) have been added. Formats for Macedonian have been fixed (trailing dot removed, [#23532](#)).
- Added quoting of constraint names in the SQL generated by migrations to prevent crash with uppercase characters in the name ([#23065](#)).

- Fixed renaming of models with a self-referential many-to-many field (`ManyToManyField('self')`) (#23503).
- Added the `get_extra()`, `get_max_num()`, and `get_min_num()` hooks to `GenericInlineModelAdmin` (#23539).
- Made `migrations.RunSQL` no longer require percent sign escaping. This is now consistent with `cursor.execute()` (#23426).
- Made the `SERIALIZE` entry in the `TEST` dictionary usable (#23421).
- Fixed bug in migrations that prevented foreign key constraints to unmanaged models with a custom primary key (#23415).
- Added `SchemaEditor` for MySQL GIS backend so that spatial indexes will be created for apps with migrations (#23538).
- Added `SchemaEditor` for Oracle GIS backend so that spatial metadata and indexes will be created for apps with migrations (#23537).
- Coerced the `related_name` model field option to Unicode during migration generation to generate migrations that work with both Python 2 and 3 (#23455).
- Fixed `MigrationWriter` to handle builtin types without imports (#23560).
- Fixed `deepcopy` on `ErrorList` (#23594).
- Made the `admindocs` view to browse view details check if the view specified in the URL exists in the `URLconf`. Previously it was possible to import arbitrary packages from the Python path. This was not considered a security issue because `admindocs` is only accessible to staff users (#23601).
- Fixed `UnicodeDecodeError` crash in `AdminEmailHandler` with non-ASCII characters in the request (#23593).
- Fixed missing `get_or_create` and `update_or_create` on related managers causing `IntegrityError` (#23611).
- Made `urlsafe_base64_decode()` return the proper type (`bytestring`) on Python 3 (#23333).
- `makemigrations` can now serialize timezone-aware values (#23365).
- Added a prompt to the migrations questioner when removing the null constraint from a field to prevent an `IntegrityError` on existing NULL rows (#23609).
- Fixed generic relations in `ModelAdmin.list_filter` (#23616).
- Restored RFC compliance for the SMTP backend on Python 3 (#23063).
- Fixed a crash while parsing cookies containing invalid content (#23638).
- The system check framework now raises error `models.E020` when the class method `Model.check()` is unreachable (#23615).

- Made the Oracle test database creation drop the test user in the event of an unclean exit of a previous test run (#23649).
- Fixed *makemigrations* to detect changes to *Meta.db_table* (#23629).
- Fixed a regression when feeding the Django test client with an empty data string (#21740).
- Fixed a regression in *makemessages* where static files were unexpectedly ignored (#23583).

Django 1.7 release notes

September 2, 2014

Welcome to Django 1.7!

These release notes cover the [new features](#), as well as some [backwards incompatible changes](#) you'll want to be aware of when upgrading from Django 1.6 or older versions. We've [begun the deprecation process for some features](#), and some features have reached the end of their deprecation process and [have been removed](#).

Python compatibility

Django 1.7 requires Python 2.7, 3.2, 3.3, or 3.4. We highly recommend and only officially support the latest release of each series.

The Django 1.6 series is the last to support Python 2.6. Django 1.7 is the first release to support Python 3.4.

This change should affect only a small number of Django users, as most operating-system vendors today are shipping Python 2.7 or newer as their default version. If you're still using Python 2.6, however, you'll need to stick to Django 1.6 until you can upgrade your Python version. Per [our support policy](#), Django 1.6 will continue to receive security support until the release of Django 1.8.

What's new in Django 1.7

Schema migrations

Django now has built-in support for schema migrations. It allows models to be updated, changed, and deleted by creating migration files that represent the model changes and which can be run on any development, staging or production database.

Migrations are covered in [their own documentation](#), but a few of the key features are:

- *syncdb* has been deprecated and replaced by *migrate*. Don't worry - calls to *syncdb* will still work as before.
- A new *makemigrations* command provides an easy way to autodetect changes to your models and make migrations for them.

`django.db.models.signals.pre_syncdb` and `django.db.models.signals.post_syncdb` have been deprecated, to be replaced by `pre_migrate` and `post_migrate` respectively. These new signals have slightly different arguments. Check the documentation for details.

- The `allow_syncdb` method on database routers is now called `allow_migrate`, but still performs the same function. Routers with `allow_syncdb` methods will still work, but that method name is deprecated and you should change it as soon as possible (nothing more than renaming is required).
- `initial_data` fixtures are no longer loaded for apps with migrations; if you want to load initial data for an app, we suggest you create a migration for your application and define a `RunPython` or `RunSQL` operation in the `operations` section of the migration.
- Test rollback behavior is different for apps with migrations; in particular, Django will no longer emulate rollbacks on non-transactional databases or inside `TransactionTestCase` unless specifically requested.
- It is not advised to have apps without migrations depend on (have a `ForeignKey` or `ManyToManyField` to) apps with migrations.

App-loading refactor

Historically, Django applications were tightly linked to models. A singleton known as the “app cache” dealt with both installed applications and models. The models module was used as an identifier for applications in many APIs.

As the concept of Django applications matured, this code showed some shortcomings. It has been refactored into an “app registry” where models modules no longer have a central role and where it’s possible to attach configuration data to applications.

Improvements thus far include:

- Applications can run code at startup, before Django does anything else, with the `ready()` method of their configuration.
- Application labels are assigned correctly to models even when they’re defined outside of `models.py`. You don’t have to set `app_label` explicitly any more.
- It is possible to omit `models.py` entirely if an application doesn’t have any models.
- Applications can be relabeled with the `label` attribute of application configurations, to work around label conflicts.
- The name of applications can be customized in the admin with the `verbose_name` of application configurations.
- The admin automatically calls `autodiscover()` when Django starts. You can consequently remove this line from your `URLconf`.
- Django imports all application configurations and models as soon as it starts, through a deterministic and straightforward process. This should make it easier to diagnose import issues such as import loops.

New method on Field subclasses

To help power both schema migrations and to enable easier addition of composite keys in future releases of Django, the *Field* API now has a new required method: `deconstruct()`.

This method takes no arguments, and returns a tuple of four items:

- **name:** The field's attribute name on its parent model, or `None` if it is not part of a model
- **path:** A dotted, Python path to the class of this field, including the class name.
- **args:** Positional arguments, as a list
- **kwargs:** Keyword arguments, as a dict

These four values allow any field to be serialized into a file, as well as allowing the field to be copied safely, both essential parts of these new features.

This change should not affect you unless you write custom Field subclasses; if you do, you may need to reimplement the `deconstruct()` method if your subclass changes the method signature of `__init__` in any way. If your field just inherits from a built-in Django field and doesn't override `__init__`, no changes are necessary.

If you do need to override `deconstruct()`, a good place to start is the built-in Django fields (`django/db/models/fields/__init__.py`) as several fields, including `DecimalField` and `DateField`, override it and show how to call the method on the superclass and simply add or remove extra arguments.

This also means that all arguments to fields must themselves be serializable; to see what we consider serializable, and to find out how to make your own classes serializable, read the [migration serialization documentation](#).

Calling custom QuerySet methods from the Manager

Historically, the recommended way to make reusable model queries was to create methods on a custom `Manager` class. The problem with this approach was that after the first method call, you'd get back a `QuerySet` instance and couldn't call additional custom manager methods.

Though not documented, it was common to work around this issue by creating a custom `QuerySet` so that custom methods could be chained; but the solution had a number of drawbacks:

- The custom `QuerySet` and its custom methods were lost after the first call to `values()` or `values_list()`.
- Writing a custom `Manager` was still necessary to return the custom `QuerySet` class and all methods that were desired on the `Manager` had to be proxied to the `QuerySet`. The whole process went against the DRY principle.

The `QuerySet.as_manager()` class method can now directly create `Manager` with `QuerySet` methods:

```
class FoodQuerySet(models.QuerySet):
    def pizzas(self):
        return self.filter(kind="pizza")

    def vegetarian(self):
        return self.filter(vegetarian=True)

class Food(models.Model):
    kind = models.CharField(max_length=50)
    vegetarian = models.BooleanField(default=False)
    objects = FoodQuerySet.as_manager()

Food.objects.pizzas().vegetarian()
```

Using a custom manager when traversing reverse relations

It is now possible to [specify a custom manager](#) when traversing a reverse relationship:

```
class Blog(models.Model):
    pass

class Entry(models.Model):
    blog = models.ForeignKey(Blog)

    objects = models.Manager() # Default Manager
    entries = EntryManager() # Custom Manager

b = Blog.objects.get(id=1)
b.entry_set(manager="entries").all()
```

New system check framework

We've added a new [System check framework](#) for detecting common problems (like invalid models) and providing hints for resolving those problems. The framework is extensible so you can add your own checks for your own apps and libraries.

To perform system checks, you use the [check](#) management command. This command replaces the older `validate` management command.

New Prefetch object for advanced prefetch_related operations.

The new *Prefetch* object allows customizing prefetch operations.

You can specify the `QuerySet` used to traverse a given relation or customize the storage location of prefetch results.

This enables things like filtering prefetched relations, calling *select_related()* from a prefetched relation, or prefetching the same relation multiple times with different querysets. See *prefetch_related()* for more details.

Admin shortcuts support time zones

The “today” and “now” shortcuts next to date and time input widgets in the admin are now operating in the *current time zone*. Previously, they used the browser time zone, which could result in saving the wrong value when it didn’t match the current time zone on the server.

In addition, the widgets now display a help message when the browser and server time zone are different, to clarify how the value inserted in the field will be interpreted.

Using database cursors as context managers

Prior to Python 2.7, database cursors could be used as a context manager. The specific backend’s cursor defined the behavior of the context manager. The behavior of magic method lookups was changed with Python 2.7 and cursors were no longer usable as context managers.

Django 1.7 allows a cursor to be used as a context manager. That is, the following can be used:

```
with connection.cursor() as c:
    c.execute(...)
```

instead of:

```
c = connection.cursor()
try:
    c.execute(...)
finally:
    c.close()
```

Custom lookups

It is now possible to write custom lookups and transforms for the ORM. Custom lookups work just like Django's built-in lookups (e.g. `lte`, `icontains`) while transforms are a new concept.

The `django.db.models.Lookup` class provides a way to add lookup operators for model fields. As an example it is possible to add `day_lte` operator for `DateFields`.

The `django.db.models.Transform` class allows transformations of database values prior to the final lookup. For example it is possible to write a `year` transform that extracts year from the field's value. Transforms allow for chaining. After the `year` transform has been added to `DateField` it is possible to filter on the transformed value, for example `qs.filter(author__birthdate__year__lte=1981)`.

For more information about both custom lookups and transforms refer to the [custom lookups](#) documentation.

Improvements to Form error handling

`Form.add_error()`

Previously there were two main patterns for handling errors in forms:

- Raising a `ValidationError` from within certain functions (e.g. `Field.clean()`, `Form.clean_<fieldname>()`, or `Form.clean()` for non-field errors.)
- Fiddling with `Form._errors` when targeting a specific field in `Form.clean()` or adding errors from outside of a “clean” method (e.g. directly from a view).

Using the former pattern was straightforward since the form can guess from the context (i.e. which method raised the exception) where the errors belong and automatically process them. This remains the canonical way of adding errors when possible. However the latter was fiddly and error-prone, since the burden of handling edge cases fell on the user.

The new `add_error()` method allows adding errors to specific form fields from anywhere without having to worry about the details such as creating instances of `django.forms.utils.ErrorList` or dealing with `Form.cleaned_data`. This new API replaces manipulating `Form._errors` which now becomes a private API.

See [Cleaning and validating fields that depend on each other](#) for an example using `Form.add_error()`.

Error metadata

The `ValidationError` constructor accepts metadata such as `error_code` or `params` which are then available for interpolating into the error message (see [Raising ValidationError](#) for more details); however, before Django 1.7 those metadata were discarded as soon as the errors were added to `Form.errors`.

`Form.errors` and `django.forms.utils.ErrorList` now store the `ValidationError` instances so these metadata can be retrieved at any time through the new `Form.errors.as_data` method.

The retrieved `ValidationError` instances can then be identified thanks to their error code which enables things like rewriting the error's message or writing custom logic in a view when a given error is present. It can also be used to serialize the errors in a custom format such as XML.

The new `Form.errors.as_json()` method is a convenience method which returns error messages along with error codes serialized as JSON. `as_json()` uses `as_data()` and gives an idea of how the new system could be extended.

Error containers and backward compatibility

Heavy changes to the various error containers were necessary in order to support the features above, specifically `Form.errors`, `django.forms.utils.ErrorList`, and the internal storages of `ValidationError`. These containers which used to store error strings now store `ValidationError` instances and public APIs have been adapted to make this as transparent as possible, but if you've been using private APIs, some of the changes are backwards incompatible; see [ValidationError constructor and internal storage](#) for more details.

Minor features

`django.contrib.admin`

- You can now implement `site_header`, `site_title`, and `index_title` attributes on a custom `AdminSite` in order to easily change the admin site's page title and header text. No more needing to override templates!
- Buttons in `django.contrib.admin` now use the `border-radius` CSS property for rounded corners rather than GIF background images.
- Some admin templates now have `app-<app_name>` and `model-<model_name>` classes in their `<body>` tag to allow customizing the CSS per app or per model.
- The admin changelist cells now have a `field-<field_name>` class in the HTML to enable style customizations.
- The admin's search fields can now be customized per-request thanks to the new `django.contrib.admin.ModelAdmin.get_search_fields()` method.
- The `ModelAdmin.get_fields()` method may be overridden to customize the value of `ModelAdmin.fields`.
- In addition to the existing `admin.site.register` syntax, you can use the new `register()` decorator to register a `ModelAdmin`.
- You may specify `ModelAdmin.list_display_links = None` to disable links on the change list page grid.

- You may now specify `ModelAdmin.view_on_site` to control whether or not to display the “View on site” link.
- You can specify a descending ordering for a `ModelAdmin.list_display` value by prefixing the `admin_order_field` value with a hyphen.
- The `ModelAdmin.get_changeform_initial_data()` method may be overridden to define custom behavior for setting initial change form data.

`django.contrib.auth`

- Any `**kwargs` passed to `email_user()` are passed to the underlying `send_mail()` call.
- The `permission_required()` decorator can take a list of permissions as well as a single permission.
- You can override the new `AuthenticationForm.confirm_login_allowed()` method to more easily customize the login policy.
- `django.contrib.auth.views.password_reset()` takes an optional `html_email_template_name` parameter used to send a multipart HTML email for password resets.
- The `AbstractBaseUser.get_session_auth_hash()` method was added and if your `AUTH_USER_MODEL` inherits from `AbstractBaseUser`, changing a user’s password now invalidates old sessions if the `django.contrib.auth.middleware.SessionAuthenticationMiddleware` is enabled. See [Session invalidation on password change](#) for more details.

`django.contrib.formtools`

- Calls to `WizardView.done()` now include a `form_dict` to allow easier access to forms by their step name.

`django.contrib.gis`

- The default OpenLayers library version included in widgets has been updated from 2.11 to 2.13.
- Prepared geometries now also support the `crosses`, `disjoint`, `overlaps`, `touches` and `within` predicates, if GEOS 3.3 or later is installed.

`django.contrib.messages`

- The backends for `django.contrib.messages` that use cookies, will now follow the `SESSION_COOKIE_SECURE` and `SESSION_COOKIE_HTTPONLY` settings.
- The `messages` context processor now adds a dictionary of default levels under the name `DEFAULT_MESSAGE_LEVELS`.
- `Message` objects now have a `level_tag` attribute that contains the string representation of the message level.

`django.contrib.redirects`

- `RedirectFallbackMiddleware` has two new attributes (`response_gone_class` and `response_redirect_class`) that specify the types of `HttpResponse` instances the middleware returns.

`django.contrib.sessions`

- The `"django.contrib.sessions.backends.cached_db"` session backend now respects `SESSION_CACHE_ALIAS`. In previous versions, it always used the default cache.

`django.contrib.sitemaps`

- The `sitemap framework` now makes use of `lastmod` to set a Last-Modified header in the response. This makes it possible for the `ConditionalGetMiddleware` to handle conditional GET requests for sitemaps which set `lastmod`.

`django.contrib.sites`

- The new `django.contrib.sites.middleware.CurrentSiteMiddleware` allows setting the current site on each request.

`django.contrib.staticfiles`

- The `static files storage classes` may be subclassed to override the permissions that collected static files and directories receive by setting the `file_permissions_mode` and `directory_permissions_mode` parameters. See `collectstatic` for example usage.
- The `CachedStaticFilesStorage` backend gets a sibling class called `ManifestStaticFilesStorage` that doesn't use the cache system at all but instead a JSON file called `staticfiles.json` for storing

the mapping between the original file name (e.g. `css/styles.css`) and the hashed file name (e.g. `css/styles.55e7cbb9ba48.css`). The `staticfiles.json` file is created when running the `collectstatic` management command and should be a less expensive alternative for remote storages such as Amazon S3.

See the *ManifestStaticFilesStorage* docs for more information.

- `findstatic` now accepts verbosity flag level 2, meaning it will show the relative paths of the directories it searched. See `findstatic` for example output.

`django.contrib.syndication`

- The *Atom1Feed* syndication feed's `updated` element now utilizes `updateddate` instead of `pubdate`, allowing the `published` element to be included in the feed (which relies on `pubdate`).

Cache

- Access to caches configured in *CACHES* is now available via `django.core.cache.caches`. This dict-like object provides a different instance per thread. It supersedes `django.core.cache.get_cache()` which is now deprecated.
- If you instantiate cache backends directly, be aware that they aren't thread-safe any more, as `django.core.cache.caches` now yields different instances per thread.
- Defining the *TIMEOUT* argument of the *CACHES* setting as `None` will set the cache keys as “non-expiring” by default. Previously, it was only possible to pass `timeout=None` to the cache backend's `set()` method.

Cross Site Request Forgery

- The *CSRF_COOKIE_AGE* setting facilitates the use of session-based CSRF cookies.

Email

- `send_mail()` now accepts an `html_message` parameter for sending a multipart *text/plain* and *text/html* email.
- The SMTP *EmailBackend* now accepts a `timeout` parameter.

File Storage

- File locking on Windows previously depended on the PyWin32 package; if it wasn't installed, file locking failed silently. That dependency has been removed, and file locking is now implemented natively on both Windows and Unix.

File Uploads

- The new `UploadedFile.content_type_extra` attribute contains extra parameters passed to the `content-type` header on a file upload.
- The new `FILE_UPLOAD_DIRECTORY_PERMISSIONS` setting controls the file system permissions of directories created during file upload, like `FILE_UPLOAD_PERMISSIONS` does for the files themselves.
- The `FileField.upload_to` attribute is now optional. If it is omitted or given `None` or an empty string, a subdirectory won't be used for storing the uploaded files.
- Uploaded files are now explicitly closed before the response is delivered to the client. Partially uploaded files are also closed as long as they are named `file` in the upload handler.
- `Storage.get_available_name()` now appends an underscore plus a random 7 character alphanumeric string (e.g. `"_x3a1gho"`), rather than iterating through an underscore followed by a number (e.g. `"_1"`, `"_2"`, etc.) to prevent a denial-of-service attack. This change was also made in the 1.6.6, 1.5.9, and 1.4.14 security releases.

Forms

- The `<label>` and `<input>` tags rendered by `RadioSelect` and `CheckboxSelectMultiple` when looping over the radio buttons or checkboxes now include `for` and `id` attributes, respectively. Each radio button or checkbox includes an `id_for_label` attribute to output the element's ID.
- The `<textarea>` tags rendered by `Textarea` now include a `maxlength` attribute if the `TextField` model field has a `max_length`.
- `Field.choices` now allows you to customize the “empty choice” label by including a tuple with an empty string or `None` for the key and the custom label as the value. The default blank option `"-----"` will be omitted in this case.
- `MultiValueField` allows optional subfields by setting the `require_all_fields` argument to `False`. The `required` attribute for each individual field will be respected, and a new `incomplete` validation error will be raised when any required fields are empty.
- The `clean()` method on a form no longer needs to return `self.cleaned_data`. If it does return a changed dictionary then that will still be used.

- After a temporary regression in Django 1.6, it's now possible again to make `TypedChoiceField` `coerce` method return an arbitrary value.
- `SelectDateWidget.months` can be used to customize the wording of the months displayed in the select widget.
- The `min_num` and `validate_min` parameters were added to `formset_factory()` to allow validating a minimum number of submitted forms.
- The metaclasses used by `Form` and `ModelForm` have been reworked to support more inheritance scenarios. The previous limitation that prevented inheriting from both `Form` and `ModelForm` simultaneously have been removed as long as `ModelForm` appears first in the MRO.
- It's now possible to remove a field from a `Form` when subclassing by setting the name to `None`.
- It's now possible to customize the error messages for `ModelForm`'s `unique`, `unique_for_date`, and `unique_together` constraints. In order to support `unique_together` or any other `NON_FIELD_ERROR`, `ModelForm` now looks for the `NON_FIELD_ERROR` key in the `error_messages` dictionary of the `ModelForm`'s inner `Meta` class. See [considerations regarding model's error_messages](#) for more details.

Internationalization

- The `django.middleware.locale.LocaleMiddleware.response_redirect_class` attribute allows you to customize the redirects issued by the middleware.
- The `LocaleMiddleware` now stores the user's selected language with the session key `_language`. This should only be accessed using the `LANGUAGE_SESSION_KEY` constant. Previously it was stored with the key `django_language` and the `LANGUAGE_SESSION_KEY` constant did not exist, but keys reserved for Django should start with an underscore. For backwards compatibility `django_language` is still read from in 1.7. Sessions will be migrated to the new key as they are written.
- The `blocktrans` tag now supports a `trimmed` option. This option will remove newline characters from the beginning and the end of the content of the `{% blocktrans %}` tag, replace any whitespace at the beginning and end of a line and merge all lines into one using a space character to separate them. This is quite useful for indenting the content of a `{% blocktrans %}` tag without having the indentation characters end up in the corresponding entry in the `.po` file, which makes the translation process easier.
- When you run `makemessages` from the root directory of your project, any extracted strings will now be automatically distributed to the proper app or project message file. See [Localization: how to create language files](#) for details.
- The `makemessages` command now always adds the `--previous` command line flag to the `msgmerge` command, keeping previously translated strings in `.po` files for fuzzy strings.
- The following settings to adjust the language cookie options were introduced: `LANGUAGE_COOKIE_AGE`, `LANGUAGE_COOKIE_DOMAIN` and `LANGUAGE_COOKIE_PATH`.

- Added [Format localization](#) for Esperanto.

Management Commands

- The new `--no-color` option for `django-admin` disables the colorization of management command output.
- The new `dumpdata --natural-foreign` and `dumpdata --natural-primary` options, and the new `use_natural_foreign_keys` and `use_natural_primary_keys` arguments for `serializers.serialize()`, allow the use of natural primary keys when serializing.
- It is no longer necessary to provide the cache table name or the `--database` option for the `createcachetable` command. Django takes this information from your settings file. If you have configured multiple caches or multiple databases, all cache tables are created.
- The `runserver` command received several improvements:
 - On Linux systems, if `pyinotify` is installed, the development server will reload immediately when a file is changed. Previously, it polled the filesystem for changes every second. That caused a small delay before reloads and reduced battery life on laptops.
 - In addition, the development server automatically reloads when a translation file is updated, i.e. after running `compilemessages`.
 - All HTTP requests are logged to the console, including requests for static files or `favicon.ico` that used to be filtered out.
- Management commands can now produce syntax colored output under Windows if the ANSICON third-party tool is installed and active.
- `collectstatic` command with `symlink` option is now supported on Windows NT 6 (Windows Vista and newer).
- Initial SQL data now works better if the `sqlparse` Python library is installed.

Note that it's deprecated in favor of the `RunSQL` operation of migrations, which benefits from the improved behavior.

Models

- The `QuerySet.update_or_create()` method was added.
- The new `default_permissions` model Meta option allows you to customize (or disable) creation of the default add, change, and delete permissions.
- Explicit `OneToOneField` for [Multi-table inheritance](#) are now discovered in abstract classes.
- It is now possible to avoid creating a backward relation for `OneToOneField` by setting its `related_name` to '+' or ending it with '+'

- *F expressions* support the power operator (`**`).
- The `remove()` and `clear()` methods of the related managers created by `ForeignKey` and `GenericForeignKey` now accept the `bulk` keyword argument to control whether or not to perform operations in bulk (i.e. using `QuerySet.update()`). Defaults to `True`.
- It is now possible to use `None` as a query value for the *exact* lookup.
- It is now possible to pass a callable as value for the attribute *limit_choices_to* when defining a `ForeignKey` or `ManyToManyField`.
- Calling *only()* and *defer()* on the result of *QuerySet.values()* now raises an error (before that, it would either result in a database error or incorrect data).
- You can use a single list for *index_together* (rather than a list of lists) when specifying a single set of fields.
- Custom intermediate models having more than one foreign key to any of the models participating in a many-to-many relationship are now permitted, provided you explicitly specify which foreign keys should be used by setting the new *ManyToManyField.through_fields* argument.
- Assigning a model instance to a non-relation field will now throw an error. Previously this used to work if the field accepted integers as input as it took the primary key.
- Integer fields are now validated against database backend specific min and max values based on their *internal_type*. Previously model field validation didn't prevent values out of their associated column data type range from being saved resulting in an integrity error.
- It is now possible to explicitly *order_by()* a relation `_id` field by using its attribute name.

Signals

- The `enter` argument was added to the *setting_changed* signal.
- The model signals can now be connected to using a `str` of the `'app_label.ModelName'` form –just like related fields –to lazily reference their senders.

Templates

- The *Context.push()* method now returns a context manager which automatically calls *pop()* upon exiting the `with` statement. Additionally, *push()* now accepts parameters that are passed to the dict constructor used to build the new context level.
- The new *Context.flatten()* method returns a `Context`'s stack as one flat dictionary.
- `Context` objects can now be compared for equality (internally, this uses *Context.flatten()* so the internal structure of each `Context`'s stack doesn't matter as long as their flattened version is identical).
- The *widthratio* template tag now accepts an `"as"` parameter to capture the result in a variable.

- The `include` template tag will now also accept anything with a `render()` method (such as a `Template`) as an argument. String arguments will be looked up using `get_template()` as always.
- It is now possible to `include` templates recursively.
- Template objects now have an `origin` attribute set when `TEMPLATE_DEBUG` is `True`. This allows template origins to be inspected and logged outside of the `django.template` infrastructure.
- `TypeError` exceptions are no longer silenced when raised during the rendering of a template.
- The following functions now accept a `dirs` parameter which is a list or tuple to override `TEMPLATE_DIRS`:
 - `django.template.loader.get_template()`
 - `django.template.loader.select_template()`
 - `django.shortcuts.render()`
 - `django.shortcuts.render_to_response()`
- The `time` filter now accepts timezone-related `format specifiers` 'e', 'O', 'T' and 'Z' and is able to digest `time-zone-aware` `datetime` instances performing the expected rendering.
- The `cache` tag will now try to use the cache called “`template_fragments`” if it exists and fall back to using the default cache otherwise. It also now accepts an optional `using` keyword argument to control which cache it uses.
- The new `truncatechars_html` filter truncates a string to be no longer than the specified number of characters, taking HTML into account.

Requests and Responses

- The new `HttpRequest.scheme` attribute specifies the scheme of the request (`http` or `https` normally).
- The shortcut `redirect()` now supports relative URLs.
- The new `JsonResponse` subclass of `HttpResponse` helps easily create JSON-encoded responses.

Tests

- `DiscoverRunner` has two new attributes, `test_suite` and `test_runner`, which facilitate overriding the way tests are collected and run.
- The `fetch_redirect_response` argument was added to `assertRedirects()`. Since the test client can't fetch external URLs, this allows you to use `assertRedirects` with redirects that aren't part of your Django app.
- Correct handling of scheme when making comparisons in `assertRedirects()`.

- The `secure` argument was added to all the request methods of *Client*. If `True`, the request will be made through HTTPS.
- `assertNumQueries()` now prints out the list of executed queries if the assertion fails.
- The `WSGIRequest` instance generated by the test handler is now attached to the `django.test.Response.wsgi_request` attribute.
- The database settings for testing have been collected into a dictionary named `TEST`.

Utilities

- Improved `strip_tags()` accuracy (but it still cannot guarantee an HTML-safe result, as stated in the documentation).

Validators

- *RegexValidator* now accepts the optional `flags` and Boolean `inverse_match` arguments. The `inverse_match` attribute determines if the *ValidationError* should be raised when the regular expression pattern matches (`True`) or does not match (`False`, by default) the provided value. The `flags` attribute sets the flags used when compiling a regular expression string.
- *URLValidator* now accepts an optional `schemes` argument which allows customization of the accepted URI schemes (instead of the defaults `http(s)` and `ftp(s)`).
- `validate_email()` now accepts addresses with IPv6 literals, like `example@[2001:db8::1]`, as specified in RFC 5321.

Backwards incompatible changes in 1.7

Warning: In addition to the changes outlined in this section, be sure to review the [deprecation plan](#) for any features that have been removed. If you haven't updated your code within the deprecation timeline for a given feature, its removal may appear as a backwards incompatible change.

`allow_syncdb` / `allow_migrate`

While Django will still look at `allow_syncdb` methods even though they should be renamed to `allow_migrate`, there is a subtle difference in which models get passed to these methods.

For apps with migrations, `allow_migrate` will now get passed [historical models](#), which are special versioned models without custom attributes, methods or managers. Make sure your `allow_migrate` methods are only referring to fields or other items in `model._meta`.

`initial_data`

Apps with migrations will not load `initial_data` fixtures when they have finished migrating. Apps without migrations will continue to load these fixtures during the phase of `migrate` which emulates the old `syncdb` behavior, but any new apps will not have this support.

Instead, you are encouraged to load initial data in migrations if you need it (using the `RunPython` operation and your model classes); this has the added advantage that your initial data will not need updating every time you change the schema.

Additionally, like the rest of Django's old `syncdb` code, `initial_data` has been started down the deprecation path and will be removed in Django 1.9.

`deconstruct()` and serializability

Django now requires all Field classes and all of their constructor arguments to be serializable. If you modify the constructor signature in your custom Field in any way, you'll need to implement a `deconstruct()` method; we've expanded the custom field documentation with [instructions on implementing this method](#).

The requirement for all field arguments to be [serializable](#) means that any custom class instances being passed into Field constructors - things like custom Storage subclasses, for instance - need to have a [deconstruct method defined on them as well](#), though Django provides a handy class decorator that will work for most applications.

App-loading changes

Start-up sequence

Django 1.7 loads application configurations and models as soon as it starts. While this behavior is more straightforward and is believed to be more robust, regressions cannot be ruled out. See [Troubleshooting](#) for solutions to some problems you may encounter.

Standalone scripts

If you're using Django in a plain Python script —rather than a management command— and you rely on the `DJANGO_SETTINGS_MODULE` environment variable, you must now explicitly initialize Django at the beginning of your script with:

```
>>> import django
>>> django.setup()
```

Otherwise, you will hit an `AppRegistryNotReady` exception.

WSGI scripts

Until Django 1.3, the recommended way to create a WSGI application was:

```
import django.core.handlers.wsgi

application = django.core.handlers.wsgi.WSGIHandler()
```

In Django 1.4, support for WSGI was improved and the API changed to:

```
from django.core.wsgi import get_wsgi_application

application = get_wsgi_application()
```

If you're still using the former style in your WSGI script, you need to upgrade to the latter, or you will hit an `AppRegistryNotReady` exception.

App registry consistency

It is no longer possible to have multiple installed applications with the same label. In previous versions of Django, this didn't always work correctly, but didn't crash outright either.

If you have two apps with the same label, you should create an *AppConfig* for one of them and override its *label* there. You should then adjust your code wherever it references this application or its models with the old label.

It isn't possible to import the same model twice through different paths any more. As of Django 1.6, this may happen only if you're manually putting a directory and a subdirectory on `PYTHONPATH`. Refer to the section on the new project layout in the [1.4 release notes](#) for migration instructions.

You should make sure that:

- All models are defined in applications that are listed in *INSTALLED_APPS* or have an explicit *app_label*.
- Models aren't imported as a side-effect of loading their application. Specifically, you shouldn't import models in the root module of an application nor in the module that define its configuration class.

Django will enforce these requirements as of version 1.9, after a deprecation period.

Subclassing `AppCommand`

Subclasses of `AppCommand` must now implement a `handle_app_config()` method instead of `handle_app()`. This method receives an `AppConfig` instance instead of a models module.

Introspecting applications

Since `INSTALLED_APPS` now supports application configuration classes in addition to application modules, you should review code that accesses this setting directly and use the app registry (`django.apps.apps`) instead.

The app registry has preserved some features of the old app cache. Even though the app cache was a private API, obsolete methods and arguments will be removed through a standard deprecation path, with the exception of the following changes that take effect immediately:

- `get_model` raises `LookupError` instead of returning `None` when no model is found.
- The `only_installed` argument of `get_model` and `get_models` no longer exists, nor does the `seed_cache` argument of `get_model`.

Management commands and order of `INSTALLED_APPS`

When several applications provide management commands with the same name, Django loads the command from the application that comes first in `INSTALLED_APPS`. Previous versions loaded the command from the application that came last.

This brings discovery of management commands in line with other parts of Django that rely on the order of `INSTALLED_APPS`, such as static files, templates, and translations.

`ValidationError` constructor and internal storage

The behavior of the `ValidationError` constructor has changed when it receives a container of errors as an argument (e.g. a list or an `ErrorList`):

- It converts any strings it finds to instances of `ValidationError` before adding them to its internal storage.
- It doesn't store the given container but rather copies its content to its own internal storage; previously the container itself was added to the `ValidationError` instance and used as internal storage.

This means that if you access the `ValidationError` internal storages, such as `error_list`; `error_dict`; or the return value of `update_error_dict()` you may find instances of `ValidationError` where you would have previously found strings.

Also if you directly assigned the return value of `update_error_dict()` to `Form._errors` you may inadvertently add list instances where `ErrorList` instances are expected. This is a problem because unlike a simple list, an `ErrorList` knows how to handle instances of `ValidationError`.

Most use-cases that warranted using these private APIs are now covered by the newly introduced `Form.add_error()` method:

```
# Old pattern:
try:
    ...
except ValidationError as e:
    self._errors = e.update_error_dict(self._errors)

# New pattern:
try:
    ...
except ValidationError as e:
    self.add_error(None, e)
```

If you need both Django <= 1.6 and 1.7 compatibility you can't use `Form.add_error()` since it wasn't available before Django 1.7, but you can use the following workaround to convert any list into `ErrorList`:

```
try:
    ...
except ValidationError as e:
    self._errors = e.update_error_dict(self._errors)

# Additional code to ensure ``ErrorDict`` is exclusively
# composed of ``ErrorList`` instances.
for field, error_list in self._errors.items():
    if not isinstance(error_list, self.error_class):
        self._errors[field] = self.error_class(error_list)
```

Behavior of `LocMemCache` regarding pickle errors

An inconsistency existed in previous versions of Django regarding how pickle errors are handled by different cache backends. `django.core.cache.backends.locmem.LocMemCache` used to fail silently when such an error occurs, which is inconsistent with other backends and leads to cache-specific errors. This has been fixed in Django 1.7, see [#21200](#) for more details.

Cache keys are now generated from the request's absolute URL

Previous versions of Django generated cache keys using a request's path and query string but not the scheme or host. If a Django application was serving multiple subdomains or domains, cache keys could collide. In Django 1.7, cache keys vary by the absolute URL of the request including scheme, host, path, and query string. For example, the URL portion of a cache key is now generated from `https://www.example.com/path/to/?key=val` rather than `/path/to/?key=val`. The cache keys generated by Django 1.7 will be different from the keys generated by older versions of Django. After upgrading to Django 1.7, the first request to any previously cached URL will be a cache miss.

Passing None to `Manager.db_manager()`

In previous versions of Django, it was possible to use `db_manager(using=None)` on a model manager instance to obtain a manager instance using default routing behavior, overriding any manually specified database routing. In Django 1.7, a value of `None` passed to `db_manager` will produce a router that retains any manually assigned database routing—the manager will not be reset. This was necessary to resolve an inconsistency in the way routing information cascaded over joins. See [#13724](#) for more details.

pytz may be required

If your project handles datetimes before 1970 or after 2037 and Django raises a `ValueError` when encountering them, you will have to install `pytz`. You may be affected by this problem if you use Django's time zone-related date formats or `django.contrib.syndication`.

`remove()` and `clear()` methods of related managers

The `remove()` and `clear()` methods of the related managers created by `ForeignKey`, `GenericForeignKey`, and `ManyToManyField` suffered from a number of issues. Some operations ran multiple data modifying queries without wrapping them in a transaction, and some operations didn't respect default filtering when it was present (i.e. when the default manager on the related model implemented a custom `get_queryset()`).

Fixing the issues introduced some backward incompatible changes:

- The default implementation of `remove()` for `ForeignKey` related managers changed from a series of `Model.save()` calls to a single `QuerySet.update()` call. The change means that `pre_save` and `post_save` signals aren't sent anymore. You can use the `bulk=False` keyword argument to revert to the previous behavior.
- The `remove()` and `clear()` methods for `GenericForeignKey` related managers now perform bulk delete. The `Model.delete()` method isn't called on each instance anymore. You can use the `bulk=False` keyword argument to revert to the previous behavior.

- The `remove()` and `clear()` methods for `ManyToManyField` related managers perform nested queries when filtering is involved, which may or may not be an issue depending on your database and your data itself. See [this note](#) for more details.

Admin login redirection strategy

Historically, the Django admin site passed the request from an unauthorized or unauthenticated user directly to the login view, without HTTP redirection. In Django 1.7, this behavior changed to conform to a more traditional workflow where any unauthorized request to an admin page will be redirected (by HTTP status code 302) to the login page, with the `next` parameter set to the referring path. The user will be redirected there after a successful login.

Note also that the admin login form has been updated to not contain the `this_is_the_login_form` field (now unused) and the `ValidationError` code has been set to the more regular `invalid_login` key.

`select_for_update()` requires a transaction

Historically, queries that use `select_for_update()` could be executed in autocommit mode, outside of a transaction. Before Django 1.6, Django's automatic transactions mode allowed this to be used to lock records until the next write operation. Django 1.6 introduced database-level autocommit; since then, execution in such a context voids the effect of `select_for_update()`. It is, therefore, assumed now to be an error and raises an exception.

This change was made because such errors can be caused by including an app which expects global transactions (e.g. `ATOMIC_REQUESTS` set to `True`), or Django's old autocommit behavior, in a project which runs without them; and further, such errors may manifest as data-corruption bugs. It was also made in Django 1.6.3.

This change may cause test failures if you use `select_for_update()` in a test class which is a subclass of `TransactionTestCase` rather than `TestCase`.

Contrib middleware removed from default `MIDDLEWARE_CLASSES`

The [app-loading refactor](#) deprecated using models from apps which are not part of the `INSTALLED_APPS` setting. This exposed an incompatibility between the default `INSTALLED_APPS` and `MIDDLEWARE_CLASSES` in the global defaults (`django.conf.global_settings`). To bring these settings in sync and prevent deprecation warnings when doing things like testing reusable apps with minimal settings, `SessionMiddleware`, `AuthenticationMiddleware`, and `MessageMiddleware` were removed from the defaults. These classes will still be included in the default settings generated by `startproject`. Most projects will not be affected by this change but if you were not previously declaring the `MIDDLEWARE_CLASSES` in your project settings and relying on the global default you should ensure that the new defaults are in line with your project's needs. You should also check for any code that accesses `django.conf.global_settings.MIDDLEWARE_CLASSES` directly.

Miscellaneous

- The `django.core.files.uploadhandler.FileUploadHandler.new_file()` method is now passed an additional `content_type_extra` parameter. If you have a custom `FileUploadHandler` that implements `new_file()`, be sure it accepts this new parameter.
- `ModelFormSets` no longer delete instances when `save(commit=False)` is called. See `can_delete` for instructions on how to manually delete objects from deleted forms.
- Loading empty fixtures emits a `RuntimeWarning` rather than raising `CommandError`.
- `django.contrib.staticfiles.views.serve()` will now raise an `Http404` exception instead of `ImproperlyConfigured` when `DEBUG` is `False`. This change removes the need to conditionally add the view to your root `URLconf`, which in turn makes it safe to reverse by name. It also removes the ability for visitors to generate spurious HTTP 500 errors by requesting static files that don't exist or haven't been collected yet.
- The `django.db.models.Model.__eq__()` method is now defined in a way where instances of a proxy model and its base model are considered equal when primary keys match. Previously only instances of exact same class were considered equal on primary key match.
- The `django.db.models.Model.__eq__()` method has changed such that two `Model` instances without primary key values won't be considered equal (unless they are the same instance).
- The `django.db.models.Model.__hash__()` method will now raise `TypeError` when called on an instance without a primary key value. This is done to avoid mutable `__hash__` values in containers.
- `AutoField` columns in SQLite databases will now be created using the `AUTOINCREMENT` option, which guarantees monotonic increments. This will cause primary key numbering behavior to change on SQLite, becoming consistent with most other SQL databases. This will only apply to newly created tables. If you have a database created with an older version of Django, you will need to migrate it to take advantage of this feature. For example, you could do the following:
 - 1) Use `dumpdata` to save your data.
 - 2) Rename the existing database file (keep it as a backup).
 - 3) Run `migrate` to create the updated schema.
 - 4) Use `loaddata` to import the fixtures you exported in (1).
- `django.contrib.auth.models.AbstractUser` no longer defines a `get_absolute_url()` method. The old definition returned `"/users/%s/" % urlquote(self.username)` which was arbitrary since applications may or may not define such a url in `urlpatterns`. Define a `get_absolute_url()` method on your own custom user object or use `ABSOLUTE_URL_OVERRIDES` if you want a URL for your user.
- The static asset-serving functionality of the `django.test.LiveServerTestCase` class has been simplified: Now it's only able to serve content already present in `STATIC_ROOT` when tests are run. The ability to transparently serve all the static assets (similarly to what one gets with `DEBUG =`

`True` at development-time) has been moved to a new class that lives in the `staticfiles` application (the one actually in charge of such feature): `django.contrib.staticfiles.testing.StaticLiveServerTestCase`. In other words, `LiveServerTestCase` itself is less powerful but at the same time has less magic.

Rationale behind this is removal of dependency of non-contrib code on contrib applications.

- The old cache URI syntax (e.g. "locmem://") is no longer supported. It still worked, even though it was not documented or officially supported. If you're still using it, please update to the current `CACHES` syntax.
- The default ordering of `Form` fields in case of inheritance has changed to follow normal Python MRO. Fields are now discovered by iterating through the MRO in reverse with the topmost class coming last. This only affects you if you relied on the default field ordering while having fields defined on both the current class and on a parent `Form`.
- The `required` argument of `SelectDateWidget` has been removed. This widget now respects the form field's `is_required` attribute like other widgets.
- `Widget.is_hidden` is now a read-only property, getting its value by introspecting the presence of `input_type == 'hidden'`.
- `select_related()` now chains in the same way as other similar calls like `prefetch_related`. That is, `select_related('foo', 'bar')` is equivalent to `select_related('foo').select_related('bar')`. Previously the latter would have been equivalent to `select_related('bar')`.
- GeoDjango dropped support for GEOS < 3.1.
- The `init_connection_state` method of database backends now executes in autocommit mode (unless you set `AUTOCOMMIT` to `False`). If you maintain a custom database backend, you should check that method.
- The `django.db.backends.BaseDatabaseFeatures.allows_primary_key_0` attribute has been renamed to `allows_auto_pk_0` to better describe it. It's `True` for all database backends included with Django except MySQL which does allow primary keys with value 0. It only forbids autoincrement primary keys with value 0.
- Shadowing model fields defined in a parent model has been forbidden as this creates ambiguity in the expected model behavior. In addition, clashing fields in the model inheritance hierarchy result in a system check error. For example, if you use multi-inheritance, you need to define custom primary key fields on parent models, otherwise the default id fields will clash. See [Multiple inheritance](#) for details.
- `django.utils.translation.parse_accept_lang_header()` now returns lowercase locales, instead of the case as it was provided. As locales should be treated case-insensitive this allows us to speed up locale detection.
- `django.utils.translation.get_language_from_path()` and `django.utils.translation.trans_real.get_supported_language_variant()` now no longer have a `supported` argument.

- The `shortcut` view in `django.contrib.contenttypes.views` now supports protocol-relative URLs (e.g. `//example.com`).
- `GenericRelation` now supports an optional `related_query_name` argument. Setting `related_query_name` adds a relation from the related object back to the content type for filtering, ordering and other query operations.
- When running tests on PostgreSQL, the `USER` will need read access to the built-in `postgres` database. This is in lieu of the previous behavior of connecting to the actual non-test database.
- As part of the `System check framework`, `fields`, `models`, and `model managers` all implement a `check()` method that is registered with the check framework. If you have an existing method called `check()` on one of these objects, you will need to rename it.
- As noted above in the “Cache” section of “Minor Features”, defining the `TIMEOUT` argument of the `CACHES` setting as `None` will set the cache keys as “non-expiring”. Previously, with the memcache backend, a `TIMEOUT` of 0 would set non-expiring keys, but this was inconsistent with the set-and-expire (i.e. no caching) behavior of `set("key", "value", timeout=0)`. If you want non-expiring keys, please update your settings to use `None` instead of 0 as the latter now designates set-and-expire in the settings as well.
- The `sql*` management commands now respect the `allow_migrate()` method of `DATABASE_ROUTERS`. If you have models synced to non-default databases, use the `--database` flag to get SQL for those models (previously they would always be included in the output).
- Decoding the query string from URLs now falls back to the ISO-8859-1 encoding when the input is not valid UTF-8.
- With the addition of the `django.contrib.auth.middleware.SessionAuthenticationMiddleware` to the default project template (pre-1.7.2 only), a database must be created before accessing a page using `runserver`.
- The addition of the `schemes` argument to `URLValidator` will appear as a backwards-incompatible change if you were previously using a custom regular expression to validate schemes. Any scheme not listed in `schemes` will fail validation, even if the regular expression matches the given URL.

Features deprecated in 1.7

`django.core.cache.get_cache`

`django.core.cache.get_cache` has been supplanted by `django.core.cache.caches`.

`django.utils.dictconfig/django.utils.importlib`

`django.utils.dictconfig` and `django.utils.importlib` were copies of respectively `logging.config` and `importlib` provided for Python versions prior to 2.7. They have been deprecated.

`django.utils.module_loading.import_by_path`

The current `django.utils.module_loading.import_by_path` function catches `AttributeError`, `ImportError`, and `ValueError` exceptions, and re-raises *`ImproperlyConfigured`*. Such exception masking makes it needlessly hard to diagnose circular import problems, because it makes it look like the problem comes from inside Django. It has been deprecated in favor of *`import_string()`*.

`django.utils.tzinfo`

`django.utils.tzinfo` provided two `tzinfo` subclasses, `LocalTimezone` and `FixedOffset`. They've been deprecated in favor of more correct alternatives provided by *`django.utils.timezone`*, *`django.utils.timezone.get_default_timezone()`* and *`django.utils.timezone.get_fixed_timezone()`*.

`django.utils.unittest`

`django.utils.unittest` provided uniform access to the `unittest2` library on all Python versions. Since `unittest2` became the standard library's `unittest` module in Python 2.7, and Django 1.7 drops support for older Python versions, this module isn't useful anymore. It has been deprecated. Use `unittest` instead.

`django.utils.datastructures.SortedDict`

As `OrderedDict` was added to the standard library in Python 2.7, `SortedDict` is no longer needed and has been deprecated.

The two additional, deprecated methods provided by `SortedDict` (`insert()` and `value_for_index()`) have been removed. If you relied on these methods to alter structures like form fields, you should now treat these `OrderedDicts` as immutable objects and override them to change their content.

For example, you might want to override `MyFormClass.base_fields` (although this attribute isn't considered a public API) to change the ordering of fields for all `MyFormClass` instances; or similarly, you could override `self.fields` from inside `MyFormClass.__init__()`, to change the fields for a particular form instance. For example (from Django itself):

```
PasswordChangeForm.base_fields = OrderedDict(
    (k, PasswordChangeForm.base_fields[k])
    for k in ["old_password", "new_password1", "new_password2"]
)
```

Custom SQL location for models package

Previously, if models were organized in a package (`myapp/models/`) rather than simply `myapp/models.py`, Django would look for initial SQL data in `myapp/models/sql/`. This bug has been fixed so that Django will search `myapp/sql/` as documented. After this issue was fixed, migrations were added which deprecates initial SQL data. Thus, while this change still exists, the deprecation is irrelevant as the entire feature will be removed in Django 1.9.

Reorganization of `django.contrib.sites`

`django.contrib.sites` provides reduced functionality when it isn't in `INSTALLED_APPS`. The app-loading refactor adds some constraints in that situation. As a consequence, two objects were moved, and the old locations are deprecated:

- *RequestSite* now lives in `django.contrib.sites.requests`.
- *get_current_site()* now lives in `django.contrib.sites.shortcuts`.

`declared_fieldsets` attribute on `ModelAdmin`

`ModelAdmin.declared_fieldsets` has been deprecated. Despite being a private API, it will go through a regular deprecation path. This attribute was mostly used by methods that bypassed `ModelAdmin.get_fieldsets()` but this was considered a bug and has been addressed.

Reorganization of `django.contrib.contenttypes`

Since `django.contrib.contenttypes.generic` defined both admin and model related objects, an import of this module could trigger unexpected side effects. As a consequence, its contents were split into *contenttypes* submodules and the `django.contrib.contenttypes.generic` module is deprecated:

- *GenericForeignKey* and *GenericRelation* now live in *fields*.
- *BaseGenericInlineFormSet* and *generic_inlineformset_factory()* now live in *forms*.
- *GenericInlineModelAdmin*, *GenericStackedInline* and *GenericTabularInline* now live in *admin*.

syncdb

The `syncdb` command has been deprecated in favor of the new `migrate` command. `migrate` takes the same arguments as `syncdb` used to plus a few more, so it's safe to just change the name you're calling and nothing else.

util modules renamed to utils

The following instances of `util.py` in the Django codebase have been renamed to `utils.py` in an effort to unify all `util` and `utils` references:

- `django.contrib.admin.util`
- `django.contrib.gis.db.backends.util`
- `django.db.backends.util`
- `django.forms.util`

get_formsets method on ModelAdmin

`ModelAdmin.get_formsets` has been deprecated in favor of the new `get_formsets_with_inlines()`, in order to better handle the case of selectively showing inlines on a `ModelAdmin`.

IPAddressField

The `django.db.models.IPAddressField` and `django.forms.IPAddressField` fields have been deprecated in favor of `django.db.models.GenericIPAddressField` and `django.forms.GenericIPAddressField`.

BaseMemcachedCache._get_memcache_timeout method

The `BaseMemcachedCache._get_memcache_timeout()` method has been renamed to `get_backend_timeout()`. Despite being a private API, it will go through the normal deprecation.

Natural key serialization options

The `--natural` and `-n` options for `dumpdata` have been deprecated. Use `dumpdata --natural-foreign` instead.

Similarly, the `use_natural_keys` argument for `serializers.serialize()` has been deprecated. Use `use_natural_foreign_keys` instead.

Merging of POST and GET arguments into `WSGIRequest.REQUEST`

It was already strongly suggested that you use GET and POST instead of REQUEST, because the former are more explicit. The property REQUEST is deprecated and will be removed in Django 1.9.

`django.utils.datastructures.MergeDict` class

MergeDict exists primarily to support merging POST and GET arguments into a REQUEST property on WSGIRequest. To merge dictionaries, use `dict.update()` instead. The class MergeDict is deprecated and will be removed in Django 1.9.

Language codes `zh-cn`, `zh-tw` and `fy-nl`

The currently used language codes for Simplified Chinese `zh-cn`, Traditional Chinese `zh-tw` and (Western) Frysian `fy-nl` are deprecated and should be replaced by the language codes `zh-hans`, `zh-hant` and `fy` respectively. If you use these language codes, you should rename the locale directories and update your settings to reflect these changes. The deprecated language codes will be removed in Django 1.9.

`django.utils.functional.memoize` function

The function `memoize` is deprecated and should be replaced by the `functools.lru_cache` decorator (available from Python 3.2 onward).

Django ships a backport of this decorator for older Python versions and it's available at `django.utils.lru_cache.lru_cache`. The deprecated function will be removed in Django 1.9.

Geo Sitemaps

Google has retired support for the Geo Sitemaps format. Hence Django support for Geo Sitemaps is deprecated and will be removed in Django 1.8.

Passing callable arguments to queryset methods

Callable arguments for querysets were an undocumented feature that was unreliable. It's been deprecated and will be removed in Django 1.9.

Callable arguments were evaluated when a queryset was constructed rather than when it was evaluated, thus this feature didn't offer any benefit compared to evaluating arguments before passing them to queryset and created confusion that the arguments may have been evaluated at query time.

ADMIN_FOR setting

The ADMIN_FOR feature, part of the admin docs, has been removed. You can remove the setting from your configuration at your convenience.

SplitDateTimeWidget with DateTimeField

SplitDateTimeWidget support in *DateTimeField* is deprecated, use SplitDateTimeWidget with *SplitDateTimeField* instead.

validate

The validate management command is deprecated in favor of the *check* command.

django.core.management.BaseCommand

requires_model_validation is deprecated in favor of a new requires_system_checks flag. If the latter flag is missing, then the value of the former flag is used. Defining both requires_system_checks and requires_model_validation results in an error.

The check() method has replaced the old validate() method.

ModelAdmin validators

The ModelAdmin.validator_class and default_validator_class attributes are deprecated in favor of the new checks_class attribute.

The ModelAdmin.validate() method is deprecated in favor of ModelAdmin.check().

The django.contrib.admin.validation module is deprecated.

django.db.backends.DatabaseValidation.validate_field

This method is deprecated in favor of a new check_field method. The functionality required by check_field() is the same as that provided by validate_field(), but the output format is different. Third-party database backends needing this functionality should provide an implementation of check_field().

Loading ssi and url template tags from future library

Django 1.3 introduced `{% load ssi from future %}` and `{% load url from future %}` syntax for forward compatibility of the `ssi` and `url` template tags. This syntax is now deprecated and will be removed in Django 1.9. You can simply remove the `{% load ... from future %}` tags.

`django.utils.text.javascript_quote`

`javascript_quote()` was an undocumented function present in `django.utils.text`. It was used internally in the `javascript_catalog()` view whose implementation was changed to make use of `json.dumps()` instead. If you were relying on this function to provide safe output from untrusted strings, you should use `django.utils.html.escapejs` or the `escapejs` template filter. If all you need is to generate valid JavaScript strings, you can simply use `json.dumps()`.

`fix_ampersands` utils method and template filter

The `django.utils.html.fix_ampersands` method and the `fix_ampersands` template filter are deprecated, as the escaping of ampersands is already taken care of by Django's standard HTML escaping features. Combining this with `fix_ampersands` would either result in double escaping, or, if the output is assumed to be safe, a risk of introducing XSS vulnerabilities. Along with `fix_ampersands`, `django.utils.html.clean_html` is deprecated, an undocumented function that calls `fix_ampersands`. As this is an accelerated deprecation, `fix_ampersands` and `clean_html` will be removed in Django 1.8.

Reorganization of database test settings

All database settings with a `TEST_` prefix have been deprecated in favor of entries in a `TEST` dictionary in the database settings. The old settings will be supported until Django 1.9. For backwards compatibility with older versions of Django, you can define both versions of the settings as long as they match.

FastCGI support

FastCGI support via the `runfcgi` management command will be removed in Django 1.9. Please deploy your project using WSGI.

Moved objects in `contrib.sites`

Following the app-loading refactor, two objects in `django.contrib.sites.models` needed to be moved because they must be available without importing `django.contrib.sites.models` when `django.contrib.sites` isn't installed. Import `RequestSite` from `django.contrib.sites.requests` and `get_current_site()` from `django.contrib.sites.shortcuts`. The old import locations will work until Django 1.9.

`django.forms.forms.get_declared_fields()`

Django no longer uses this functional internally. Even though it's a private API, it'll go through the normal deprecation cycle.

Private Query Lookup APIs

Private APIs `django.db.models.sql.where.WhereNode.make_atom()` and `django.db.models.sql.where.Constraint` are deprecated in favor of the new [custom lookups API](#).

Features removed in 1.7

These features have reached the end of their deprecation cycle and are removed in Django 1.7. See [Features deprecated in 1.5](#) for details, including how to remove usage of these features.

- `django.utils.simplejson` is removed.
- `django.utils.itercompat.product` is removed.
- `INSTALLED_APPS` and `TEMPLATE_DIRS` are no longer corrected from a plain string into a tuple.
- `HttpResponse`, `SimpleTemplateResponse`, `TemplateResponse`, `render_to_response()`, `index()`, and `sitemap()` no longer take a `mimetype` argument
- `HttpResponse` immediately consumes its content if it's an iterator.
- The `AUTH_PROFILE_MODULE` setting, and the `get_profile()` method on the `User` model are removed.
- The `cleanup` management command is removed.
- The `daily_cleanup.py` script is removed.
- `select_related()` no longer has a `depth` keyword argument.
- The `get_warnings_state()/restore_warnings_state()` functions from `django.test.utils` and the `save_warnings_state()/restore_warnings_state()` `django.test.TestCase` are removed.
- The `check_for_test_cookie` method in `AuthenticationForm` is removed.

- The version of `django.contrib.auth.views.password_reset_confirm()` that supports base36 encoded user IDs (`django.contrib.auth.views.password_reset_confirm_uidb36`) is removed.
- The `django.utils.encoding.StrAndUnicode` mix-in is removed.

9.1.15 1.6 release

Django 1.6.11 release notes

March 18, 2015

Django 1.6.11 fixes two security issues in 1.6.10.

Denial-of-service possibility with `strip_tags()`

Last year `strip_tags()` was changed to work iteratively. The problem is that the size of the input it's processing can increase on each iteration which results in an infinite loop in `strip_tags()`. This issue only affects versions of Python that haven't received a [bugfix in HTMLParser](#); namely Python < 2.7.7 and 3.3.5. Some operating system vendors have also backported the fix for the Python bug into their packages of earlier versions.

To remedy this issue, `strip_tags()` will now return the original input if it detects the length of the string it's processing increases. Remember that absolutely NO guarantee is provided about the results of `strip_tags()` being HTML safe. So NEVER mark safe the result of a `strip_tags()` call without escaping it first, for example with `escape()`.

Mitigated possible XSS attack via user-supplied redirect URLs

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()` and [i18n](#)) to redirect the user to an “on success” URL. The security checks for these redirects (namely `django.utils.http.is_safe_url()`) accepted URLs with leading control characters and so considered URLs like `\x08javascript:... safe`. This issue doesn't affect Django currently, since we only put this URL into the `Location` response header and browsers seem to ignore JavaScript there. Browsers we tested also treat URLs prefixed with control characters such as `%08//example.com` as relative paths so redirection to an unsafe target isn't a problem either.

However, if a developer relies on `is_safe_url()` to provide safe redirect targets and puts such a URL into a link, they could suffer from an XSS attack as some browsers such as Google Chrome ignore control characters at the start of a URL in an anchor `href`.

Django 1.6.10 release notes

January 13, 2015

Django 1.6.10 fixes several security issues in 1.6.9.

WSGI header spoofing via underscore/dash conflation

When HTTP headers are placed into the WSGI environ, they are normalized by converting to uppercase, converting all dashes to underscores, and prepending HTTP_. For instance, a header `X-Auth-User` would become `HTTP_X_AUTH_USER` in the WSGI environ (and thus also in Django's `request.META` dictionary).

Unfortunately, this means that the WSGI environ cannot distinguish between headers containing dashes and headers containing underscores: `X-Auth-User` and `X-Auth_User` both become `HTTP_X_AUTH_USER`. This means that if a header is used in a security-sensitive way (for instance, passing authentication information along from a front-end proxy), even if the proxy carefully strips any incoming value for `X-Auth-User`, an attacker may be able to provide an `X-Auth_User` header (with underscore) and bypass this protection.

In order to prevent such attacks, both Nginx and Apache 2.4+ strip all headers containing underscores from incoming requests by default. Django's built-in development server now does the same. Django's development server is not recommended for production use, but matching the behavior of common production servers reduces the surface area for behavior changes during deployment.

Mitigated possible XSS attack via user-supplied redirect URLs

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()` and [i18n](#)) to redirect the user to an “on success” URL. The security checks for these redirects (namely `django.utils.http.is_safe_url()`) didn't strip leading whitespace on the tested URL and as such considered URLs like `\njavascript:... safe`. If a developer relied on `is_safe_url()` to provide safe redirect targets and put such a URL into a link, they could suffer from a XSS attack. This bug doesn't affect Django currently, since we only put this URL into the `Location` response header and browsers seem to ignore JavaScript there.

Denial-of-service attack against `django.views.static.serve`

In older versions of Django, the `django.views.static.serve()` view read the files it served one line at a time. Therefore, a big file with no newlines would result in memory usage equal to the size of that file. An attacker could exploit this and launch a denial-of-service attack by simultaneously requesting many large files. This view now reads the file in chunks to prevent large memory usage.

Note, however, that this view has always carried a warning that it is not hardened for production use and should be used only as a development aid. Now may be a good time to audit your project and serve your files in production using a real front-end web server if you are not doing so.

Database denial-of-service with `ModelMultipleChoiceField`

Given a form that uses `ModelMultipleChoiceField` and `show_hidden_initial=True` (not a documented API), it was possible for a user to cause an unreasonable number of SQL queries by submitting duplicate values for the field's data. The validation logic in `ModelMultipleChoiceField` now deduplicates submitted values to address this issue.

Django 1.6.9 release notes

January 2, 2015

Django 1.6.9 fixes a regression in the 1.6.6 security release.

Additionally, Django's vendored version of `six`, `django.utils.six`, has been upgraded to the latest release (1.9.0).

Bugfixes

- Fixed a regression with dynamically generated inlines and allowed field references in the admin ([#23754](#)).

Django 1.6.8 release notes

October 22, 2014

Django 1.6.8 fixes a couple regressions in the 1.6.6 security release.

Bugfixes

- Allowed related many-to-many fields to be referenced in the admin ([#23604](#)).
- Allowed inline and hidden references to admin fields ([#23431](#)).

Django 1.6.7 release notes

September 2, 2014

Django 1.6.7 fixes several bugs in 1.6.6, including a regression related to a security fix in that release.

Bugfixes

- Allowed inherited and m2m fields to be referenced in the admin (#23329).
- Fixed a crash when using `QuerySet.defer()` with `select_related()` (#23370).

Django 1.6.6 release notes

August 20, 2014

Django 1.6.6 fixes several security issues and bugs in 1.6.5.

`reverse()` could generate URLs pointing to other hosts

In certain situations, URL reversing could generate scheme-relative URLs (URLs starting with two slashes), which could unexpectedly redirect a user to a different host. An attacker could exploit this, for example, by redirecting users to a phishing site designed to ask for user's passwords.

To remedy this, URL reversing now ensures that no URL starts with two slashes (`//`), replacing the second slash with its URL encoded counterpart (`%2F`). This approach ensures that semantics stay the same, while making the URL relative to the domain and not to the scheme.

File upload denial-of-service

Before this release, Django's file upload handling in its default configuration may degrade to producing a huge number of `os.stat()` system calls when a duplicate filename is uploaded. Since `stat()` may invoke IO, this may produce a huge data-dependent slowdown that slowly worsens over time. The net result is that given enough time, a user with the ability to upload files can cause poor performance in the upload handler, eventually causing it to become very slow simply by uploading 0-byte files. At this point, even a slow network connection and few HTTP requests would be all that is necessary to make a site unavailable.

We've remedied the issue by changing the algorithm for generating file names if a file with the uploaded name already exists. `Storage.get_available_name()` now appends an underscore plus a random 7 character alphanumeric string (e.g. `"_x3a1gho"`), rather than iterating through an underscore followed by a number (e.g. `"_1"`, `"_2"`, etc.).

RemoteUserMiddleware session hijacking

When using the *RemoteUserMiddleware* and the *RemoteUserBackend*, a change to the `REMOTE_USER` header between requests without an intervening logout could result in the prior user's session being co-opted by the subsequent user. The middleware now logs the user out on a failed login attempt.

Data leakage via query string manipulation in `contrib.admin`

In older versions of Django it was possible to reveal any field's data by modifying the “popup” and “to_field” parameters of the query string on an admin change form page. For example, requesting a URL like `/admin/auth/user/?_popup=1&t=password` and viewing the page's HTML allowed viewing the password hash of each user. While the admin requires users to have permissions to view the change form pages in the first place, this could leak data if you rely on users having access to view only certain fields on a model.

To address the issue, an exception will now be raised if a `to_field` value that isn't a related field to a model that has been registered with the admin is specified.

Bugfixes

- Corrected email and URL validation to reject a trailing dash (#22579).
- Prevented indexes on PostgreSQL virtual fields (#22514).
- Prevented edge case where values of FK fields could be initialized with a wrong value when an inline model formset is created for a relationship defined to point to a field other than the PK (#13794).
- Restored `pre_delete` signals for *GenericRelation* cascade deletion (#22998).
- Fixed transaction handling when specifying non-default database in `createcachetable` and `flush` (#23089).
- Fixed the “ORA-01843: not a valid month” errors when using Unicode with older versions of Oracle server (#20292).
- Restored bug fix for sending Unicode email with Python 2.6.5 and below (#19107).
- Prevented `UnicodeDecodeError` in `runserver` with non-UTF-8 and non-English locale (#23265).
- Fixed JavaScript errors while editing multi-geometry objects in the OpenLayers widget (#23137, #23293).
- Prevented a crash on Python 3 with query strings containing unencoded non-ASCII characters (#22996).

Django 1.6.5 release notes

May 14, 2014

Django 1.6.5 fixes two security issues and several bugs in 1.6.4.

Issue: Caches may incorrectly be allowed to store and serve private data

In certain situations, Django may allow caches to store private data related to a particular session and then serve that data to requests with a different session, or no session at all. This can lead to information disclosure and can be a vector for cache poisoning.

When using Django sessions, Django will set a `Vary: Cookie` header to ensure caches do not serve cached data to requests from other sessions. However, older versions of Internet Explorer (most likely only Internet Explorer 6, and Internet Explorer 7 if run on Windows XP or Windows Server 2003) are unable to handle the `Vary` header in combination with many content types. Therefore, Django would remove the header if the request was made by Internet Explorer.

To remedy this, the special behavior for these older Internet Explorer versions has been removed, and the `Vary` header is no longer stripped from the response. In addition, modifications to the `Cache-Control` header for all Internet Explorer requests with a `Content-Disposition` header have also been removed as they were found to have similar issues.

Issue: Malformed redirect URLs from user input not correctly validated

The validation for redirects did not correctly validate some malformed URLs, which are accepted by some browsers. This allows a user to be redirected to an unsafe URL unexpectedly.

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()`, `django.contrib.comments`, and `isbn`) to redirect the user to an “on success” URL. The security checks for these redirects (namely `django.utils.http.is_safe_url()`) did not correctly validate some malformed URLs, such as `http:\\\\\\\\djangoproject.com`, which are accepted by some browsers with more liberal URL parsing.

To remedy this, the validation in `is_safe_url()` has been tightened to be able to handle and correctly validate these malformed URLs.

Bugfixes

- Made the `year_lookup_bounds_for_datetime_field` Oracle backend method Python 3 compatible (#22551).
- Fixed `pgettext_lazy` crash when receiving bytestring content on Python 2 (#22565).
- Fixed the SQL generated when filtering by a negated `Q` object that contains a `F` object. (#22429).

- Avoided overwriting data fetched by `select_related()` in certain cases which could cause minor performance regressions (#22508).

Django 1.6.4 release notes

April 28, 2014

Django 1.6.4 fixes several bugs in 1.6.3.

Bugfixes

- Added backwards compatibility support for the `django.contrib.messages` cookie format of Django 1.4 and earlier to facilitate upgrading to 1.6 from 1.4 (#22426).
- Restored the ability to `reverse()` views created using `functools.partial()` (#22486).
- Fixed the `object_id` of the `LogEntry` that's created after a user password change in the admin (#22515).

Django 1.6.3 release notes

April 21, 2014

Django 1.6.3 fixes several bugs in 1.6.2, including three security issues, and makes one backwards-incompatible change:

Unexpected code execution using `reverse()`

Django's URL handling is based on a mapping of regex patterns (representing the URLs) to callable views, and Django's own processing consists of matching a requested URL against those patterns to determine the appropriate view to invoke.

Django also provides a convenience function `reverse()` –which performs this process in the opposite direction. The `reverse()` function takes information about a view and returns a URL which would invoke that view. Use of `reverse()` is encouraged for application developers, as the output of `reverse()` is always based on the current URL patterns, meaning developers do not need to change other code when making changes to URLs.

One argument signature for `reverse()` is to pass a dotted Python path to the desired view. In this situation, Django will import the module indicated by that dotted path as part of generating the resulting URL. If such a module has import-time side effects, those side effects will occur.

Thus it is possible for an attacker to cause unexpected code execution, given the following conditions:

1. One or more views are present which construct a URL based on user input (commonly, a “next” parameter in a querystring indicating where to redirect upon successful completion of an action).

2. One or more modules are known to an attacker to exist on the server's Python import path, which perform code execution with side effects on importing.

To remedy this, `reverse()` will now only accept and import dotted paths based on the view-containing modules listed in the project's [URL pattern configuration](#), so as to ensure that only modules the developer intended to be imported in this fashion can or will be imported.

Caching of anonymous pages could reveal CSRF token

Django includes both a [caching framework](#) and a system for [preventing cross-site request forgery \(CSRF\) attacks](#). The CSRF-protection system is based on a random nonce sent to the client in a cookie which must be sent by the client on future requests and, in forms, a hidden value which must be submitted back with the form.

The caching framework includes an option to cache responses to anonymous (i.e., unauthenticated) clients.

When the first anonymous request to a given page is by a client which did not have a CSRF cookie, the cache framework will also cache the CSRF cookie and serve the same nonce to other anonymous clients who do not have a CSRF cookie. This can allow an attacker to obtain a valid CSRF cookie value and perform attacks which bypass the check for the cookie.

To remedy this, the caching framework will no longer cache such responses. The heuristic for this will be:

1. If the incoming request did not submit any cookies, and
2. If the response did send one or more cookies, and
3. If the `Vary: Cookie` header is set on the response, then the response will not be cached.

MySQL typecasting

The MySQL database is known to “typecast” on certain queries; for example, when querying a table which contains string values, but using a query which filters based on an integer value, MySQL will first silently coerce the strings to integers and return a result based on that.

If a query is performed without first converting values to the appropriate type, this can produce unexpected results, similar to what would occur if the query itself had been manipulated.

Django's model field classes are aware of their own types and most such classes perform explicit conversion of query arguments to the correct database-level type before querying. However, three model field classes did not correctly convert their arguments:

- *FilePathField*
- *GenericIPAddressField*
- *IPAddressField*

These three fields have been updated to convert their arguments to the correct types before querying.

Additionally, developers of custom model fields are now warned via documentation to ensure their custom field classes will perform appropriate type conversions, and users of the `raw()` and `extra()` query methods –which allow the developer to supply raw SQL or SQL fragments –will be advised to ensure they perform appropriate manual type conversions prior to executing queries.

`select_for_update()` requires a transaction

Historically, queries that use `select_for_update()` could be executed in autocommit mode, outside of a transaction. Before Django 1.6, Django’s automatic transactions mode allowed this to be used to lock records until the next write operation. Django 1.6 introduced database-level autocommit; since then, execution in such a context voids the effect of `select_for_update()`. It is, therefore, assumed now to be an error and raises an exception.

This change was made because such errors can be caused by including an app which expects global transactions (e.g. `ATOMIC_REQUESTS` set to `True`), or Django’s old autocommit behavior, in a project which runs without them; and further, such errors may manifest as data-corruption bugs.

This change may cause test failures if you use `select_for_update()` in a test class which is a subclass of `TransactionTestCase` rather than `TestCase`.

Other bugfixes and changes

- Content retrieved from the GeoIP library is now properly decoded from its default iso-8859-1 encoding (#21996).
- Fixed `AttributeError` when using `bulk_create()` with `ForeignKey` (#21566).
- Fixed crash of `QuerySets` that use `F()` + `timedelta()` when their query was compiled more once (#21643).
- Prevented custom `widget` class attribute of `IntegerField` subclasses from being overwritten by the code in their `__init__` method (#22245).
- Improved `strip_tags()` accuracy (but it still cannot guarantee an HTML-safe result, as stated in the documentation).
- Fixed a regression in the `django.contrib.gis` SQL compiler for non-concrete fields (#22250).
- Fixed `ModelAdmin.preserve_filters` when running a site with a URL prefix (#21795).
- Fixed a crash in the `find_command` management utility when the `PATH` environment variable wasn’t set (#22256).
- Fixed `changepassword` on Windows (#22364).
- Avoided shadowing deadlock exceptions on MySQL (#22291).

- Wrapped database exceptions in `_set_autocommit` (#22321).
- Fixed atomicity when closing a database connection or when the database server disconnects (#21239 and #21202)
- Fixed regression in `prefetch_related` that caused the related objects query to include an unnecessary join (#21760).

Additionally, Django's vendored version of six, `django.utils.six` has been upgraded to the latest release (1.6.1).

Django 1.6.2 release notes

February 6, 2014

This is Django 1.6.2, a bugfix release for Django 1.6. Django 1.6.2 fixes several bugs in 1.6.1:

- Prevented the base geometry object of a prepared geometry to be garbage collected, which could lead to crash Django (#21662).
- Fixed a crash when executing the `changepassword` command when the user object representation contained non-ASCII characters (#21627).
- The `collectstatic` command will raise an error rather than default to using the current working directory if `STATIC_ROOT` is not set. Combined with the `--clear` option, the previous behavior could wipe anything below the current working directory (#21581).
- Fixed mail encoding on Python 3.3.3+ (#21093).
- Fixed an issue where when `settings.DATABASES['default']['AUTOCOMMIT'] = False`, the connection wasn't in autocommit mode but Django pretended it was.
- Fixed a regression in multiple-table inheritance `exclude()` queries (#21787).
- Added missing items to `django.utils.timezone.__all__` (#21880).
- Fixed a field misalignment issue with `select_related()` and model inheritance (#21413).
- Fixed join promotion for negated AND conditions (#21748).
- Oracle database introspection now works with boolean and float fields (#19884).
- Fixed an issue where lazy objects weren't actually marked as safe when passed through `mark_safe()` and could end up being double-escaped (#21882).

Additionally, Django's vendored version of six, `django.utils.six` has been upgraded to the latest release (1.5.2).

Django 1.6.1 release notes

December 12, 2013

This is Django 1.6.1, a bugfix release for Django 1.6. In addition to the bug fixes listed below, translations submitted since the 1.6 release are also included.

Bug fixes

- Fixed `BCryptSHA256PasswordHasher` with `py-bcrypt` and Python 3 (#21398).
- Fixed a regression that prevented a `ForeignKey` with a hidden reverse manager (`related_name` ending with `'+'`) from being used as a lookup for `prefetch_related` (#21410).
- Fixed `Queryset.datetimes` raising `AttributeError` in some situations (#21432).
- Fixed `ModelBackend` raising `UnboundLocalError` if `get_user_model()` raised an error (#21439).
- Fixed a regression that prevented editable `GenericRelation` subclasses from working in `ModelForms` (#21428).
- Added missing `to_python` method for `ModelMultipleChoiceField` which is required in Django 1.6 to properly detect changes from initial values (#21568).
- Fixed `django.contrib.humanize` translations where the Unicode sequence for the non-breaking space was returned verbatim (#21415).
- Fixed `loaddata` error when fixture file name contained any dots not related to file extensions (#21457) or when fixture path was relative but located in a subdirectory (#21551).
- Fixed display of inline instances in formsets when parent has 0 for primary key (#21472).
- Fixed a regression where custom querysets for foreign keys were overwritten if `ModelAdmin` had ordering set (#21405).
- Removed mention of a feature in the `--locale/-l` option of the `makemessages` and `compilemessages` commands that never worked as promised: Support of multiple locale names separated by commas. It's still possible to specify multiple locales in one run by using the option multiple times (#21488, #17181).
- Fixed a regression that unnecessarily triggered settings configuration when importing `get_wsgi_application` (#21486).
- Fixed test client `logout()` method when using the cookie-based session backend (#21448).
- Fixed a crash when a `GeometryField` uses a non-geometric widget (#21496).
- Fixed password hash upgrade when changing the iteration count (#21535).
- Fixed a bug in the debug view when the `URLconf` only contains one element (#21530).
- Re-added missing search result count and reset link in changelist admin view (#21510).

- The current language is no longer saved to the session by `LocaleMiddleware` on every response, but rather only after a logout (#21473).
- Fixed a crash when executing `runserver` on non-English systems and when the formatted date in its output contained non-ASCII characters (#21358).
- Fixed a crash in the debug view after an exception occurred on Python ≥ 3.3 (#21443).
- Fixed a crash in `ImageField` on some platforms (Homebrew and RHEL6 reported) (#21355).
- Fixed a regression when using generic relations in `ModelAdmin.list_filter` (#21431).

Django 1.6 release notes

Note: Dedicated to Malcolm Tredinnick

On March 17, 2013, the Django project and the free software community lost a very dear friend and developer. Malcolm was a long-time contributor to Django, a model community member, a brilliant mind, and a friend. His contributions to Django —and to many other open source projects —are nearly impossible to enumerate. Many on the core Django team had their first patches reviewed by him; his mentorship enriched us. His consideration, patience, and dedication will always be an inspiration to us.

This release of Django is for Malcolm.

—The Django Developers

November 6, 2013

Welcome to Django 1.6!

These release notes cover the [new features](#), as well as some [backwards incompatible changes](#) you’ ll want to be aware of when upgrading from Django 1.5 or older versions. We’ ve also dropped some features, which are detailed in [our deprecation plan](#), and we’ ve begun [the deprecation process for some features](#).

Python compatibility

Django 1.6, like Django 1.5, requires Python 2.6.5 or above. Python 3 is also officially supported. We highly recommend the latest minor release for each supported Python series (2.6.X, 2.7.X, 3.2.X, and 3.3.X).

Django 1.6 will be the final release series to support Python 2.6; beginning with Django 1.7, the minimum supported Python version will be 2.7.

Python 3.4 is not supported, but support will be added in Django 1.7.

What's new in Django 1.6

Simplified default project and app templates

The default templates used by `startproject` and `startapp` have been simplified and modernized. The `admin` is now enabled by default in new projects; the `sites` framework no longer is. [clickjacking prevention](#) is now on and the database defaults to SQLite.

If the default templates don't suit your tastes, you can use [custom project and app templates](#).

Improved transaction management

Django's transaction management was overhauled. Database-level autocommit is now turned on by default. This makes transaction handling more explicit and should improve performance. The existing APIs were deprecated, and new APIs were introduced, as described in the [transaction management docs](#).

Persistent database connections

Django now supports reusing the same database connection for several requests. This avoids the overhead of reestablishing a connection at the beginning of each request. For backwards compatibility, this feature is disabled by default. See [Persistent connections](#) for details.

Discovery of tests in any test module

Django 1.6 ships with a new test runner that allows more flexibility in the location of tests. The previous runner (`django.test.simple.DjangoTestSuiteRunner`) found tests only in the `models.py` and `tests.py` modules of a Python package in [INSTALLED_APPS](#).

The new runner (`django.test.runner.DiscoverRunner`) uses the test discovery features built into `unittest2` (the version of `unittest` in the Python 2.7+ standard library, and bundled with Django). With test discovery, tests can be located in any module whose name matches the pattern `test*.py`.

In addition, the test labels provided to `./manage.py test` to nominate specific tests to run must now be full Python dotted paths (or directory paths), rather than `applabel.TestCase.test_method_name` pseudo-paths. This allows running tests located anywhere in your codebase, rather than only in [INSTALLED_APPS](#). For more details, see [Testing in Django](#).

This change is backwards-incompatible; see the [backwards-incompatibility notes](#).

Time zone aware aggregation

The support for [time zones](#) introduced in Django 1.4 didn't work well with `QuerySet.dates()`: aggregation was always performed in UTC. This limitation was lifted in Django 1.6. Use `QuerySet.datetimes()` to perform time zone aware aggregation on a `DateTimeField`.

Support for savepoints in SQLite

Django 1.6 adds support for savepoints in SQLite, with some [limitations](#).

BinaryField model field

A new `django.db.models.BinaryField` model field allows storage of raw binary data in the database.

GeoDjango form widgets

GeoDjango now provides [form fields](#) and [widgets](#) for its geo-specialized fields. They are OpenLayers-based by default, but they can be customized to use any other JS framework.

check management command added for verifying compatibility

A `check` management command was added, enabling you to verify if your current configuration (currently oriented at settings) is compatible with the current version of Django.

Model.save() algorithm changed

The `Model.save()` method now tries to directly UPDATE the database if the instance has a primary key value. Previously SELECT was performed to determine if UPDATE or INSERT were needed. The new algorithm needs only one query for updating an existing row while the old algorithm needed two. See `Model.save()` for more details.

In some rare cases the database doesn't report that a matching row was found when doing an UPDATE. An example is the PostgreSQL ON UPDATE trigger which returns NULL. In such cases it is possible to set `django.db.models.Options.select_on_save` flag to force saving to use the old algorithm.

Minor features

- Authentication backends can raise `PermissionDenied` to immediately fail the authentication chain.
- The `HttpOnly` flag can be set on the CSRF cookie with `CSRF_COOKIE_HTTPONLY`.
- The `assertQuerysetEqual()` now checks for undefined order and raises `ValueError` if undefined order is spotted. The order is seen as undefined if the given `QuerySet` isn't ordered and there is more than one ordered value to compare against.
- Added `earliest()` for symmetry with `latest()`.
- In addition to `year`, `month` and `day`, the ORM now supports `hour`, `minute` and `second` lookups.
- Django now wraps all PEP 249 exceptions.
- The default widgets for `EmailField`, `URLField`, `IntegerField`, `FloatField` and `DecimalField` use the new type attributes available in HTML5 (`type='email'`, `type='url'`, `type='number'`). Note that due to erratic support of the `number` input type with localized numbers in current browsers, Django only uses it when numeric fields are not localized.
- The `number` argument for lazy plural translations can be provided at translation time rather than at definition time.
- For custom management commands: Verification of the presence of valid settings in commands that ask for it by using the `BaseCommand.can_import_settings` internal option is now performed independently from handling of the locale that should be active during the execution of the command. The latter can now be influenced by the new `BaseCommand.leave_locale_alone` internal option. See [Management commands and locales](#) for more details.
- The `success_url` of `DeletionMixin` is now interpolated with its object's `__dict__`.
- `HttpResponseRedirect` and `HttpResponsePermanentRedirect` now provide an `url` attribute (equivalent to the URL the response will redirect to).
- The `MemcachedCache` cache backend now uses the latest `pickle` protocol available.
- Added `SuccessMessageMixin` which provides a `success_message` attribute for `FormView` based classes.
- Added the `django.db.models.ForeignKey.db_constraint` and `django.db.models.ManyToManyField.db_constraint` options.
- The jQuery library embedded in the admin has been upgraded to version 1.9.1.
- Syndication feeds (`django.contrib.syndication`) can now pass extra context through to feed templates using a new `Feed.get_context_data()` callback.
- The admin list columns have a `column-<field_name>` class in the HTML so the columns header can be styled with CSS, e.g. to set a column width.
- The `isolation level` can be customized under PostgreSQL.

- The `blocktrans` template tag now respects `TEMPLATE_STRING_IF_INVALID` for variables not present in the context, just like other template constructs.
- `SimpleLazyObjects` will now present more helpful representations in shell debugging situations.
- Generic `GeometryField` is now editable with the `OpenLayers` widget in the admin.
- The documentation contains a [deployment checklist](#).
- The `diffsettings` command gained a `--all` option.
- `django.forms.fields.Field.__init__` now calls `super()`, allowing field mixins to implement `__init__()` methods that will reliably be called.
- The `validate_max` parameter was added to `BaseFormSet` and `formset_factory()`, and `ModelForm` and inline versions of the same. The behavior of validation for formsets with `max_num` was clarified. The previously undocumented behavior that hardened formsets against memory exhaustion attacks was documented, and the undocumented limit of the higher of 1000 or `max_num` forms was changed so it is always 1000 more than `max_num`.
- Added `BCryptSHA256PasswordHasher` to resolve the password truncation issue with `bcrypt`.
- `Pillow` is now the preferred image manipulation library to use with Django. `PIL` is pending deprecation (support to be removed in Django 1.8). To upgrade, you should first uninstall `PIL`, then install `Pillow`.
- `ModelForm` accepts several new Meta options.
 - Fields included in the `localized_fields` list will be localized (by setting `localize` on the form field).
 - The `labels`, `help_texts` and `error_messages` options may be used to customize the default fields, see [Overriding the default fields](#) for details.
- The `choices` argument to model fields now accepts an iterable of iterables instead of requiring an iterable of lists or tuples.
- The reason phrase can be customized in HTTP responses using `reason_phrase`.
- When giving the URL of the next page for `django.contrib.auth.views.logout()`, `django.contrib.auth.views.password_reset()`, `django.contrib.auth.views.password_reset_confirm()`, and `django.contrib.auth.views.password_change()`, you can now pass URL names and they will be resolved.
- The new `dumpdata --pks` option specifies the primary keys of objects to dump. This option can only be used with one model.
- Added `QuerySet` methods `first()` and `last()` which are convenience methods returning the first or last object matching the filters. Returns `None` if there are no objects matching.
- `View` and `RedirectView` now support HTTP PATCH method.
- `GenericForeignKey` now takes an optional `for_concrete_model` argument, which when set to `False` allows the field to reference proxy models. The default is `True` to retain the old behavior.

- The *LocaleMiddleware* now stores the active language in session if it is not present there. This prevents loss of language settings after session flush, e.g. logout.
- *SuspiciousOperation* has been differentiated into a number of subclasses, and each will log to a matching named logger under the `django.security` logging hierarchy. Along with this change, a `handler400` mechanism and default view are used whenever a *SuspiciousOperation* reaches the WSGI handler to return an `HttpResponseBadRequest`.
- The *DoesNotExist* exception now includes a message indicating the name of the attribute used for the lookup.
- The *get_or_create()* method no longer requires at least one keyword argument.
- The *SimpleTestCase* class includes a new assertion helper for testing formset errors: `django.test.SimpleTestCase.assertFormsetError()`.
- The list of related fields added to a *QuerySet* by *select_related()* can be cleared using *select_related(None)*.
- The *get_extra()* and *get_max_num()* methods on *InlineModelAdmin* may be overridden to customize the extra and maximum number of inline forms.
- Formsets now have a *total_error_count()* method.
- *ModelForm* fields can now override error messages defined in model fields by using the *error_messages* argument of a *Field*'s constructor. To take advantage of this new feature with your custom fields, see the [updated recommendation](#) for raising a *ValidationError*.
- *ModelAdmin* now preserves filters on the list view after creating, editing or deleting an object. It's possible to restore the previous behavior of clearing filters by setting the *preserve_filters* attribute to `False`.
- Added *FormMixin.get_prefix()* (which returns *FormMixin.prefix* by default) to allow customizing the *prefix* of the form.
- Raw queries (`Manager.raw()` or `cursor.execute()`) can now use the “pyformat” parameter style, where placeholders in the query are given as `'%(name)s'` and the parameters are passed as a dictionary rather than a list (except on SQLite). This has long been possible (but not officially supported) on MySQL and PostgreSQL, and is now also available on Oracle.
- The default iteration count for the PBKDF2 password hasher has been increased by 20%. This backwards compatible change will not affect existing passwords or users who have subclassed `django.contrib.auth.hashers.PBKDF2PasswordHasher` to change the default value. Passwords [will be upgraded](#) to use the new iteration count as necessary.

Backwards incompatible changes in 1.6

Warning: In addition to the changes outlined in this section, be sure to review the [deprecation plan](#) for any features that have been removed. If you haven't updated your code within the deprecation timeline for a given feature, its removal may appear as a backwards incompatible change.

New transaction management model

Behavior changes

Database-level autocommit is enabled by default in Django 1.6. While this doesn't change the general spirit of Django's transaction management, there are a few backwards-incompatibilities.

Savepoints and `assertNumQueries`

The changes in transaction management may result in additional statements to create, release or rollback savepoints. This is more likely to happen with SQLite, since it didn't support savepoints until this release.

If tests using `assertNumQueries()` fail because of a higher number of queries than expected, check that the extra queries are related to savepoints, and adjust the expected number of queries accordingly.

Autocommit option for PostgreSQL

In previous versions, database-level autocommit was only an option for PostgreSQL, and it was disabled by default. This option is now ignored and can be removed.

New test runner

In order to maintain greater consistency with Python's `unittest` module, the new test runner (`django.test.runner.DiscoverRunner`) does not automatically support some types of tests that were supported by the previous runner:

- Tests in `models.py` and `tests/__init__.py` files will no longer be found and run. Move them to a file whose name begins with `test`.
- Doctests will no longer be automatically discovered. To integrate doctests in your test suite, follow the [recommendations in the Python documentation](#).

Django bundles a modified version of the `doctest` module from the Python standard library (in `django.test._doctest`) and includes some additional doctest utilities. These utilities are deprecated and will be

removed in Django 1.8; doctest suites should be updated to work with the standard library's doctest module (or converted to `unittest`-compatible tests).

If you wish to delay updates to your test suite, you can set your `TEST_RUNNER` setting to `django.test.simple.DjangoTestSuiteRunner` to fully restore the old test behavior. `DjangoTestSuiteRunner` is deprecated but will not be removed from Django until version 1.8.

Removal of `django.contrib.gis.tests.GeoDjangoTestSuiteRunner` GeoDjango custom test runner

This is for developers working on the GeoDjango application itself and related to the item above about changes in the test runners:

The `django.contrib.gis.tests.GeoDjangoTestSuiteRunner` test runner has been removed and the standalone GeoDjango tests execution setup it implemented isn't supported anymore. To run the GeoDjango tests simply use the new `DiscoverRunner` and specify the `django.contrib.gis` app.

Custom user models in tests

The introduction of the new test runner has also slightly changed the way that test models are imported. As a result, any test that overrides `AUTH_USER_MODEL` to test behavior with one of Django's test user models (`django.contrib.auth.tests.custom_user.CustomUser` and `django.contrib.auth.tests.custom_user.ExtensionUser`) must now explicitly import the User model in your test module:

```
from django.contrib.auth.tests.custom_user import CustomUser

@override_settings(AUTH_USER_MODEL="auth.CustomUser")
class CustomUserFeatureTests(TestCase):
    def test_something(self):
        # Test code here
        ...
```

This import forces the custom user model to be registered. Without this import, the test will be unable to swap in the custom user model, and you will get an error reporting:

ImproperlyConfigured: AUTH_USER_MODEL refers to model 'auth.CustomUser' that has not been installed

Time zone-aware day, month, and week_day lookups

Django 1.6 introduces time zone support for *day*, *month*, and *week_day* lookups when *USE_TZ* is `True`. These lookups were previously performed in UTC regardless of the current time zone.

This requires [time zone definitions in the database](#). If you're using SQLite, you must install `pytz`. If you're using MySQL, you must install `pytz` and load the time zone tables with `mysql_tzinfo_to_sql`.

Addition of `QuerySet.datetimes()`

When the [time zone support](#) added in Django 1.4 was active, *QuerySet.dates()* lookups returned unexpected results, because the aggregation was performed in UTC. To fix this, Django 1.6 introduces a new API, *QuerySet.datetimes()*. This requires a few changes in your code.

`QuerySet.dates()` returns date objects

QuerySet.dates() now returns a list of `date`. It used to return a list of `datetime`.

QuerySet.datetimes() returns a list of `datetime`.

`QuerySet.dates()` no longer usable on `DateTimeField`

QuerySet.dates() raises an error if it's used on *DateTimeField* when time zone support is active. Use *QuerySet.datetimes()* instead.

`date_hierarchy` requires time zone definitions

The *date_hierarchy* feature of the admin now relies on *QuerySet.datetimes()* when it's used on a *DateTimeField*.

This requires time zone definitions in the database when *USE_TZ* is `True`. [Learn more](#).

date_list in generic views requires time zone definitions

For the same reason, accessing `date_list` in the context of a date-based generic view requires time zone definitions in the database when the view is based on a `DateTimeField` and `USE_TZ` is `True`. [Learn more](#).

New lookups may clash with model fields

Django 1.6 introduces `hour`, `minute`, and `second` lookups on `DateTimeField`. If you had model fields called `hour`, `minute`, or `second`, the new lookups will clash with you field names. Append an explicit `exact` lookup if this is an issue.

BooleanField no longer defaults to False

When a `BooleanField` doesn't have an explicit `default`, the implicit default value is `None`. In previous version of Django, it was `False`, but that didn't represent accurately the lack of a value.

Code that relies on the default value being `False` may raise an exception when saving new model instances to the database, because `None` isn't an acceptable value for a `BooleanField`. You should either specify `default=False` in the field definition, or ensure the field is set to `True` or `False` before saving the object.

Translations and comments in templates

Extraction of translations after comments

Extraction of translatable literals from templates with the `makemessages` command now correctly detects `i18n` constructs when they are located after a `{# / #}`-type comment on the same line. E.g.:

```
{# A comment #}{% trans "This literal was incorrectly ignored. Not anymore" %}
```

Location of translator comments

Comments for translators in templates specified using `{# / #}` need to be at the end of a line. If they are not, the comments are ignored and `makemessages` will generate a warning. For example:

```
{# Translators: This is ignored #}{% trans "Translate me" %}
{{ title }}{# Translators: Extracted and associated with 'Welcome' below #}
<h1>{% trans "Welcome" %}</h1>
```

Quoting in `reverse()`

When reversing URLs, Django didn't apply `django.utils.http.urlquote` to arguments before interpolating them in URL patterns. This bug is fixed in Django 1.6. If you worked around this bug by applying URL quoting before passing arguments to `reverse()`, this may result in double-quoting. If this happens, simply remove the URL quoting from your code. You will also have to replace special characters in URLs used in `assertRedirects()` with their encoded versions.

Storage of IP addresses in the comments app

The comments app now uses a `GenericIPAddressField` for storing commenters' IP addresses, to support comments submitted from IPv6 addresses. Until now, it stored them in an `IPAddressField`, which is only meant to support IPv4. When saving a comment made from an IPv6 address, the address would be silently truncated on MySQL databases, and raise an exception on Oracle. You will need to change the column type in your database to benefit from this change.

For MySQL, execute this query on your project's database:

```
ALTER TABLE django_comments MODIFY ip_address VARCHAR(39);
```

For Oracle, execute this query:

```
ALTER TABLE DJANGO_COMMENTS MODIFY (ip_address VARCHAR2(39));
```

If you do not apply this change, the behavior is unchanged: on MySQL, IPv6 addresses are silently truncated; on Oracle, an exception is generated. No database change is needed for SQLite or PostgreSQL databases.

Percent literals in `cursor.execute` queries

When you are running raw SQL queries through the `cursor.execute` method, the rule about doubling percent literals (%) inside the query has been unified. Past behavior depended on the database backend. Now, across all backends, you only need to double literal percent characters if you are also providing replacement parameters. For example:

```
# No parameters, no percent doubling
cursor.execute("SELECT foo FROM bar WHERE baz = '30%'")

# Parameters passed, non-placeholders have to be doubled
cursor.execute("SELECT foo FROM bar WHERE baz = '30%' and id = %s", [self.id])
```

SQLite users need to check and update such queries.

Help text of model form fields for `ManyToManyField` fields

HTML rendering of model form fields corresponding to *ManyToManyField* model fields used to get the hard-coded sentence:

Hold down “Control” , or “Command” on a Mac, to select more than one.

(or its translation to the active locale) imposed as the help legend shown along them if neither *model* nor *form* `help_text` attributes were specified by the user (or this string was appended to any `help_text` that was provided).

Since this happened at the model layer, there was no way to prevent the text from appearing in cases where it wasn’ t applicable such as form fields that implement user interactions that don’ t involve a keyboard and/or a mouse.

Starting with Django 1.6, as an ad-hoc temporary backward-compatibility provision, the logic to add the “Hold down. . .” sentence has been moved to the model form field layer and modified to add the text only when the associated widget is *SelectMultiple* or selected subclasses.

The change can affect you in a backward incompatible way if you employ custom model form fields and/or widgets for `ManyToManyField` model fields whose UIs do rely on the automatic provision of the mentioned hard-coded sentence. These form field implementations need to adapt to the new scenario by providing their own handling of the `help_text` attribute.

Applications that use Django *model form* facilities together with Django built-in *form fields* and *widgets* aren’ t affected but need to be aware of what’ s described in *Munging of help text of model form fields for ManyToManyField fields* below.

QuerySet iteration

The `QuerySet` iteration was changed to immediately convert all fetched rows to `Model` objects. In Django 1.5 and earlier the fetched rows were converted to `Model` objects in chunks of 100.

Existing code will work, but the amount of rows converted to objects might change in certain use cases. Such usages include partially looping over a queryset or any usage which ends up doing `__bool__` or `__contains__`.

Notably most database backends did fetch all the rows in one go already in 1.5.

It is still possible to convert the fetched rows to `Model` objects lazily by using the *iterator()* method.

BoundField.label_tag now includes the form's label_suffix

This is consistent with how methods like *Form.as_p* and *Form.as_ul* render labels.

If you manually render `label_tag` in your templates:

```
{{ form.my_field.label_tag }}: {{ form.my_field }}
```

you'll want to remove the colon (or whatever other separator you may be using) to avoid duplicating it when upgrading to Django 1.6. The following template in Django 1.6 will render identically to the above template in Django 1.5, except that the colon will appear inside the `<label>` element.

```
{{ form.my_field.label_tag }} {{ form.my_field }}
```

will render something like:

```
<label for="id_my_field">My Field:</label> <input id="id_my_field" type="text" name="my_field" />
```

If you want to keep the current behavior of rendering `label_tag` without the `label_suffix`, instantiate the form `label_suffix=''`. You can also customize the `label_suffix` on a per-field basis using the new `label_suffix` parameter on *label_tag()*.

Admin views _changelist_filters GET parameter

To achieve preserving and restoring list view filters, admin views now pass around the `_changelist_filters` GET parameter. It's important that you account for that change if you have custom admin templates or if your tests rely on the previous URLs. If you want to revert to the original behavior you can set the *preserve_filters* attribute to `False`.

django.contrib.auth.password_reset uses base 64 encoding of User PK

Past versions of Django used base 36 encoding of the `User` primary key in the password reset views and URLs (`django.contrib.auth.views.password_reset_confirm()`). Base 36 encoding is sufficient if the user primary key is an integer, however, with the introduction of custom user models in Django 1.5, that assumption may no longer be true.

`django.contrib.auth.views.password_reset_confirm()` has been modified to take a `uidb64` parameter instead of `uidb36`. If you are reversing this view, for example in a custom `password_reset_email.html` template, be sure to update your code.

A temporary shim for `django.contrib.auth.views.password_reset_confirm()` that will allow password reset links generated prior to Django 1.6 to continue to work has been added to provide backwards compatibility; this will be removed in Django 1.7. Thus, as long as your site has been running Django 1.6 for more

than `PASSWORD_RESET_TIMEOUT_DAYS`, this change will have no effect. If not (for example, if you upgrade directly from Django 1.5 to Django 1.7), then any password reset links generated before you upgrade to Django 1.7 or later won't work after the upgrade.

In addition, if you have any custom password reset URLs, you will need to update them by replacing `uidb36` with `uidb64` and the dash that follows that pattern with a slash. Also add `_` to the list of characters that may match the `uidb64` pattern.

For example:

```
url(
    r"^reset/(?P<uidb36>[0-9A-Za-z]+)-(P<token>.+)/$",
    "django.contrib.auth.views.password_reset_confirm",
    name="password_reset_confirm",
),
```

becomes:

```
url(
    r"^reset/(?P<uidb64>[0-9A-Za-z_\-]+)/(P<token>.+)/$",
    "django.contrib.auth.views.password_reset_confirm",
    name="password_reset_confirm",
),
```

You may also want to add the shim to support the old style reset links. Using the example above, you would modify the existing url by replacing `django.contrib.auth.views.password_reset_confirm` with `django.contrib.auth.views.password_reset_confirm_uidb36` and also remove the `name` argument so it doesn't conflict with the new url:

```
url(
    r"^reset/(?P<uidb36>[0-9A-Za-z]+)-(P<token>.+)/$",
    "django.contrib.auth.views.password_reset_confirm_uidb36",
),
```

You can remove this URL pattern after your app has been deployed with Django 1.6 for `PASSWORD_RESET_TIMEOUT_DAYS`.

Default session serialization switched to JSON

Historically, `django.contrib.sessions` used `pickle` to serialize session data before storing it in the backend. If you're using the `signed cookie session backend` and `SECRET_KEY` is known by an attacker (there isn't an inherent vulnerability in Django that would cause it to leak), the attacker could insert a string into their session which, when unpickled, executes arbitrary code on the server. The technique for doing so is simple and easily available on the internet. Although the cookie session storage signs the cookie-stored data to prevent tampering, a `SECRET_KEY` leak immediately escalates to a remote code execution vulnerability.

This attack can be mitigated by serializing session data using JSON rather than `pickle`. To facilitate this, Django 1.5.3 introduced a new setting, `SESSION_SERIALIZER`, to customize the session serialization format. For backwards compatibility, this setting defaulted to using `pickle` in Django 1.5.3, but we've changed the default to JSON in 1.6. If you upgrade and switch from pickle to JSON, sessions created before the upgrade will be lost. While JSON serialization does not support all Python objects like `pickle` does, we highly recommend using JSON-serialized sessions. Be aware of the following when checking your code to determine if JSON serialization will work for your application:

- JSON requires string keys, so you will likely run into problems if you are using non-string keys in `request.session`.
- Setting session expiration by passing `datetime` values to `set_expiry()` will not work as `datetime` values are not serializable in JSON. You can use integer values instead.

See the [Session serialization](#) documentation for more details.

Object Relational Mapper changes

Django 1.6 contains many changes to the ORM. These changes fall mostly in three categories:

1. Bug fixes (e.g. proper join clauses for generic relations, query combining, join promotion, and join trimming fixes)
2. Preparation for new features. For example the ORM is now internally ready for multicolumn foreign keys.
3. General cleanup.

These changes can result in some compatibility problems. For example, some queries will now generate different table aliases. This can affect `QuerySet.extra()`. In addition some queries will now produce different results. An example is `exclude(condition)` where the condition is a complex one (referencing multijoins inside `Q` objects). In many cases the affected queries didn't produce correct results in Django 1.5 but do now. Unfortunately there are also cases that produce different results, but neither Django 1.5 nor 1.6 produce correct results.

Finally, there have been many changes to the ORM internal APIs.

Miscellaneous

- The `django.db.models.query.EmptyQuerySet` can't be instantiated any more - it is only usable as a marker class for checking if `none()` has been called: `isinstance(qs.none(), EmptyQuerySet)`
- If your CSS/JavaScript code used to access HTML input widgets by type, you should review it as `type='text'` widgets might be now output as `type='email'`, `type='url'` or `type='number'` depending on their corresponding field type.

- Form field's *error_messages* that contain a placeholder should now always use a named placeholder ("Value '%(value)s' is too big" instead of "Value '%s' is too big"). See the corresponding field documentation for details about the names of the placeholders. The changes in 1.6 particularly affect *DecimalField* and *ModelMultipleChoiceField*.
- Some *error_messages* for *IntegerField*, *EmailField*, *IPAddressField*, *GenericIPAddressField*, and *SlugField* have been suppressed because they duplicated error messages already provided by validators tied to the fields.
- Due to a change in the form validation workflow, *TypedChoiceField* *coerce* method should always return a value present in the *choices* field attribute. That limitation should be lifted again in Django 1.7.
- There have been changes in the way timeouts are handled in cache backends. Explicitly passing in *timeout=None* no longer results in using the default timeout. It will now set a non-expiring timeout. Passing 0 into the memcache backend no longer uses the default timeout, and now will set-and-expire-immediately the value.
- The `django.contrib.flatpages` app used to set custom HTTP headers for debugging purposes. This functionality was not documented and made caching ineffective so it has been removed, along with its generic implementation, previously available in `django.core.xheaders`.
- The `XViewMiddleware` has been moved from `django.middleware.doc` to `django.contrib.admindocs.middleware` because it is an implementation detail of `admindocs`, proven not to be reusable in general.
- *GenericIPAddressField* will now only allow blank values if null values are also allowed. Creating a *GenericIPAddressField* where blank is allowed but null is not will trigger a model validation error because blank values are always stored as null. Previously, storing a blank value in a field which did not allow null would cause a database exception at runtime.
- If a `NoReverseMatch` exception is raised from a method when rendering a template, it is not silenced. For example, `{{ obj.view_href }}` will cause template rendering to fail if `view_href()` raises `NoReverseMatch`. There is no change to the `{% url %}` tag, it causes template rendering to fail like always when `NoReverseMatch` is raised.
- `django.test.Client.logout()` now calls `django.contrib.auth.logout()` which will send the *user_logged_out()* signal.
- Authentication views are now reversed by name, not their locations in `django.contrib.auth.views`. If you are using the views without a *name*, you should update your *urlpatterns* to use `django.conf.urls.url()` with the *name* parameter. For example:

```
(r"^reset/done/$", "django.contrib.auth.views.password_reset_complete")
```

becomes:

```
url(
    r"^reset/done/$",
    "django.contrib.auth.views.password_reset_complete",
    name="password_reset_complete",
)
```

- `RedirectView` now has a `pattern_name` attribute which allows it to choose the target by reversing the URL.
- In Django 1.4 and 1.5, a blank string was unintentionally not considered to be a valid password. This meant `set_password()` would save a blank password as an unusable password like `set_unusable_password()` does, and thus `check_password()` always returned `False` for blank passwords. This has been corrected in this release: blank passwords are now valid.
- The admin `changelist_view` previously accepted a `pop` GET parameter to signify it was to be displayed in a popup. This parameter has been renamed to `_popup` to be consistent with the rest of the admin views. You should update your custom templates if they use the previous parameter name.
- `validate_email()` now accepts email addresses with `localhost` as the domain.
- The new `makemessages --keep-pot` option prevents deleting the temporary `.pot` file generated before creating the `.po` file.
- The undocumented `django.core.servers.basehttp.WSGIServerException` has been removed. Use `socket.error` provided by the standard library instead. This change was also released in Django 1.5.5.
- The signature of `django.views.generic.base.RedirectView.get_redirect_url()` has changed and now accepts positional arguments as well (`*args`, `**kwargs`). Any unnamed captured group will now be passed to `get_redirect_url()` which may result in a `TypeError` if you don't update the signature of your custom method.

Features deprecated in 1.6

Transaction management APIs

Transaction management was completely overhauled in Django 1.6, and the current APIs are deprecated:

- `django.middleware.transaction.TransactionMiddleware`
- `django.db.transaction.autocommit`
- `django.db.transaction.commit_on_success`
- `django.db.transaction.commit_manually`
- the `TRANSACTIONS_MANAGED` setting

`django.contrib.comments`

Django's comment framework has been deprecated and is no longer supported. It will be available in Django 1.6 and 1.7, and removed in Django 1.8. Most users will be better served with a custom solution, or a hosted product like [Disqus](#).

The code formerly known as `django.contrib.comments` is [still available in an external repository](#).

Support for PostgreSQL versions older than 8.4

The end of upstream support periods was reached in December 2011 for PostgreSQL 8.2 and in February 2013 for 8.3. As a consequence, Django 1.6 sets 8.4 as the minimum PostgreSQL version it officially supports.

You're strongly encouraged to use the most recent version of PostgreSQL available, because of performance improvements and to take advantage of the native streaming replication available in PostgreSQL 9.x.

Changes to `cycle` and `firstof`

The template system generally escapes all variables to avoid XSS attacks. However, due to an accident of history, the `cycle` and `firstof` tags render their arguments as-is.

Django 1.6 starts a process to correct this inconsistency. The `future` template library provides alternate implementations of `cycle` and `firstof` that autoescape their inputs. If you're using these tags, you're encouraged to include the following line at the top of your templates to enable the new behavior:

```
{% load cycle from future %}
```

or:

```
{% load firstof from future %}
```

The tags implementing the old behavior have been deprecated, and in Django 1.8, the old behavior will be replaced with the new behavior. To ensure compatibility with future versions of Django, existing templates should be modified to use the `future` versions.

If necessary, you can temporarily disable auto-escaping with `mark_safe()` or `{% autoescape off %}`.

CACHE_MIDDLEWARE_ANONYMOUS_ONLY setting

`CacheMiddleware` and `UpdateCacheMiddleware` used to provide a way to cache requests only if they weren't made by a logged-in user. This mechanism was largely ineffective because the middleware correctly takes into account the `Vary: Cookie` HTTP header, and this header is being set on a variety of occasions, such as:

- accessing the session, or
- using CSRF protection, which is turned on by default, or
- using a client-side library which sets cookies, like [Google Analytics](#).

This makes the cache effectively work on a per-session basis regardless of the `CACHE_MIDDLEWARE_ANONYMOUS_ONLY` setting.

SEND_BROKEN_LINK_EMAILS setting

`CommonMiddleware` used to provide basic reporting of broken links by email when `SEND_BROKEN_LINK_EMAILS` is set to `True`.

Because of intractable ordering problems between *`CommonMiddleware`* and *`LocaleMiddleware`*, this feature was split out into a new middleware: *`BrokenLinkEmailsMiddleware`*.

If you're relying on this feature, you should add `'django.middleware.common.BrokenLinkEmailsMiddleware'` to your `MIDDLEWARE_CLASSES` setting and remove `SEND_BROKEN_LINK_EMAILS` from your settings.

`_has_changed` method on widgets

If you defined your own form widgets and defined the `_has_changed` method on a widget, you should now define this method on the form field itself.

`module_name` `model _meta` attribute

`Model._meta.module_name` was renamed to `model_name`. Despite being a private API, it will go through a regular deprecation path.

`get_(add|change|delete)_permission` model `_meta` methods

`Model._meta.get_(add|change|delete)_permission` methods were deprecated. Even if they were not part of the public API they'll also go through a regular deprecation path. You can replace them with `django.contrib.auth.get_permission_codename('action', Model._meta)` where 'action' is 'add', 'change', or 'delete'.

`get_query_set` and similar methods renamed to `get_queryset`

Methods that return a `QuerySet` such as `Manager.get_query_set` or `ModelAdmin.queryset` have been renamed to `get_queryset`.

If you are writing a library that implements, for example, a `Manager.get_query_set` method, and you need to support old Django versions, you should rename the method and conditionally add an alias with the old name:

```
class CustomManager(models.Manager):
    def get_queryset(self):
        pass # ...

    if django.VERSION < (1, 6):
        get_query_set = get_queryset

# For Django >= 1.6, models.Manager provides a get_query_set fallback
# that emits a warning when used.
```

If you are writing a library that needs to call the `get_queryset` method and must support old Django versions, you should write:

```
get_queryset = (
    some_manager.get_query_set
    if hasattr(some_manager, "get_query_set")
    else some_manager.get_queryset
)
return get_queryset() # etc
```

In the general case of a custom manager that both implements its own `get_queryset` method and calls that method, and needs to work with older Django versions, and libraries that have not been updated yet, it is useful to define a `get_queryset_compat` method as below and use it internally to your manager:

```
class YourCustomManager(models.Manager):
    def get_queryset(self):
        return YourCustomQuerySet() # for example
```

(continues on next page)

(continued from previous page)

```
if django.VERSION < (1, 6):
    get_query_set = get_queryset

def active(self): # for example
    return self.get_queryset_compat().filter(active=True)

def get_queryset_compat(self):
    get_queryset = (
        self.get_query_set if hasattr(self, "get_query_set") else self.get_queryset
    )
    return get_queryset()
```

This helps to minimize the changes that are needed, but also works correctly in the case of subclasses (such as `RelatedManagers` from Django 1.5) which might override either `get_query_set` or `get_queryset`.

shortcut view and URLconf

The `shortcut` view was moved from `django.views.defaults` to `django.contrib.contenttypes.views` shortly after the 1.0 release, but the old location was never deprecated. This oversight was corrected in Django 1.6 and you should now use the new location.

The URLconf `django.conf.urls.shortcut` was also deprecated. If you're including it in an URLconf, simply replace:

```
(r"^prefix/", include("django.conf.urls.shortcut")),
```

with:

```
(
    r"^prefix/(?P<content_type_id>\d+)/(?P<object_id>.*)/$",
    "django.contrib.contenttypes.views.shortcut",
),
```

ModelForm without fields or exclude

Previously, if you wanted a `ModelForm` to use all fields on the model, you could simply omit the `Meta.fields` attribute, and all fields would be used.

This can lead to security problems where fields are added to the model and, unintentionally, automatically become editable by end users. In some cases, particular with boolean fields, it is possible for this problem to be completely invisible. This is a form of [Mass assignment vulnerability](#).

For this reason, this behavior is deprecated, and using the `Meta.exclude` option is strongly discouraged. Instead, all fields that are intended for inclusion in the form should be listed explicitly in the `fields` attribute.

If this security concern really does not apply in your case, there is a shortcut to explicitly indicate that all fields should be used - use the special value `"__all__"` for the `fields` attribute:

```
class MyModelForm(ModelForm):
    class Meta:
        fields = "__all__"
        model = MyModel
```

If you have custom `ModelForms` that only need to be used in the admin, there is another option. The admin has its own methods for defining fields (`fieldsets` etc.), and so adding a list of fields to the `ModelForm` is redundant. Instead, simply omit the `Meta` inner class of the `ModelForm`, or omit the `Meta.model` attribute. Since the `ModelAdmin` subclass knows which model it is for, it can add the necessary attributes to derive a functioning `ModelForm`. This behavior also works for earlier Django versions.

UpdateView and CreateView without explicit fields

The generic views `CreateView` and `UpdateView`, and anything else derived from `ModelFormMixin`, are vulnerable to the security problem described in the section above, because they can automatically create a `ModelForm` that uses all fields for a model.

For this reason, if you use these views for editing models, you must also supply the `fields` attribute (new in Django 1.6), which is a list of model fields and works in the same way as the `ModelForm` `Meta.fields` attribute. Alternatively, you can set the `form_class` attribute to a `ModelForm` that explicitly defines the fields to be used. Defining an `UpdateView` or `CreateView` subclass to be used with a model but without an explicit list of fields is deprecated.

Munging of help text of model form fields for ManyToManyField fields

All special handling of the `help_text` attribute of `ManyToManyField` model fields performed by standard model or model form fields as described in [Help text of model form fields for ManyToManyField fields](#) above is deprecated and will be removed in Django 1.8.

Help text of these fields will need to be handled either by applications, custom form fields or widgets, just like happens with the rest of the model field types.

9.1.16 1.5 release

Django 1.5.12 release notes

January 2, 2015

Django 1.5.12 fixes a regression in the 1.5.9 security release.

Bugfixes

- Fixed a regression with dynamically generated inlines and allowed field references in the admin ([#23754](#)).

Django 1.5.11 release notes

October 22, 2014

Django 1.5.11 fixes a couple regressions in the 1.5.9 security release.

Bugfixes

- Allowed related many-to-many fields to be referenced in the admin ([#23604](#)).
- Allowed inline and hidden references to admin fields ([#23431](#)).

Django 1.5.10 release notes

September 2, 2014

Django 1.5.10 fixes a regression in the 1.5.9 security release.

Bugfixes

- Allowed inherited and m2m fields to be referenced in the admin ([#22486](#))

Django 1.5.9 release notes

August 20, 2014

Django 1.5.9 fixes several security issues in 1.5.8.

`reverse()` could generate URLs pointing to other hosts

In certain situations, URL reversing could generate scheme-relative URLs (URLs starting with two slashes), which could unexpectedly redirect a user to a different host. An attacker could exploit this, for example, by redirecting users to a phishing site designed to ask for user's passwords.

To remedy this, URL reversing now ensures that no URL starts with two slashes (`//`), replacing the second slash with its URL encoded counterpart (`%2F`). This approach ensures that semantics stay the same, while making the URL relative to the domain and not to the scheme.

File upload denial-of-service

Before this release, Django's file upload handling in its default configuration may degrade to producing a huge number of `os.stat()` system calls when a duplicate filename is uploaded. Since `stat()` may invoke IO, this may produce a huge data-dependent slowdown that slowly worsens over time. The net result is that given enough time, a user with the ability to upload files can cause poor performance in the upload handler, eventually causing it to become very slow simply by uploading 0-byte files. At this point, even a slow network connection and few HTTP requests would be all that is necessary to make a site unavailable.

We've remedied the issue by changing the algorithm for generating file names if a file with the uploaded name already exists. `Storage.get_available_name()` now appends an underscore plus a random 7 character alphanumeric string (e.g. `"_x3a1gho"`), rather than iterating through an underscore followed by a number (e.g. `"_1"`, `"_2"`, etc.).

RemoteUserMiddleware session hijacking

When using the `RemoteUserMiddleware` and the `RemoteUserBackend`, a change to the `REMOTE_USER` header between requests without an intervening logout could result in the prior user's session being co-opted by the subsequent user. The middleware now logs the user out on a failed login attempt.

Data leakage via query string manipulation in `contrib.admin`

In older versions of Django it was possible to reveal any field's data by modifying the "popup" and "to_field" parameters of the query string on an admin change form page. For example, requesting a URL like `/admin/auth/user/?pop=1&t=password` and viewing the page's HTML allowed viewing the password hash of each user. While the admin requires users to have permissions to view the change form pages in the first place, this could leak data if you rely on users having access to view only certain fields on a model.

To address the issue, an exception will now be raised if a `to_field` value that isn't a related field to a model that has been registered with the admin is specified.

Django 1.5.8 release notes

May 14, 2014

Django 1.5.8 fixes two security issues in 1.5.8.

Caches may incorrectly be allowed to store and serve private data

In certain situations, Django may allow caches to store private data related to a particular session and then serve that data to requests with a different session, or no session at all. This can lead to information disclosure and can be a vector for cache poisoning.

When using Django sessions, Django will set a `Vary: Cookie` header to ensure caches do not serve cached data to requests from other sessions. However, older versions of Internet Explorer (most likely only Internet Explorer 6, and Internet Explorer 7 if run on Windows XP or Windows Server 2003) are unable to handle the `Vary` header in combination with many content types. Therefore, Django would remove the header if the request was made by Internet Explorer.

To remedy this, the special behavior for these older Internet Explorer versions has been removed, and the `Vary` header is no longer stripped from the response. In addition, modifications to the `Cache-Control` header for all Internet Explorer requests with a `Content-Disposition` header have also been removed as they were found to have similar issues.

Malformed redirect URLs from user input not correctly validated

The validation for redirects did not correctly validate some malformed URLs, which are accepted by some browsers. This allows a user to be redirected to an unsafe URL unexpectedly.

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()`, `django.contrib.comments`, and `il8n`) to redirect the user to an “on success” URL. The security checks for these redirects (namely `django.utils.http.is_safe_url()`) did not correctly validate some malformed URLs, such as `http:\\\\\\\\djangoproject.com`, which are accepted by some browsers with more liberal URL parsing.

To remedy this, the validation in `is_safe_url()` has been tightened to be able to handle and correctly validate these malformed URLs.

Django 1.5.7 release notes

April 28, 2014

Django 1.5.7 fixes a regression in the 1.5.6 security release.

Bugfixes

- Restored the ability to `reverse()` views created using `functools.partial()` (#22486).

Django 1.5.6 release notes

April 21, 2014

Django 1.5.6 fixes several bugs in 1.5.5, including three security issues.

Unexpected code execution using `reverse()`

Django’s URL handling is based on a mapping of regex patterns (representing the URLs) to callable views, and Django’s own processing consists of matching a requested URL against those patterns to determine the appropriate view to invoke.

Django also provides a convenience function –`reverse()`–which performs this process in the opposite direction. The `reverse()` function takes information about a view and returns a URL which would invoke that view. Use of `reverse()` is encouraged for application developers, as the output of `reverse()` is always based on the current URL patterns, meaning developers do not need to change other code when making changes to URLs.

One argument signature for `reverse()` is to pass a dotted Python path to the desired view. In this situation, Django will import the module indicated by that dotted path as part of generating the resulting URL. If such a module has import-time side effects, those side effects will occur.

Thus it is possible for an attacker to cause unexpected code execution, given the following conditions:

1. One or more views are present which construct a URL based on user input (commonly, a “next” parameter in a querystring indicating where to redirect upon successful completion of an action).
2. One or more modules are known to an attacker to exist on the server’s Python import path, which perform code execution with side effects on importing.

To remedy this, `reverse()` will now only accept and import dotted paths based on the view-containing modules listed in the project’s [URL pattern configuration](#), so as to ensure that only modules the developer intended to be imported in this fashion can or will be imported.

Caching of anonymous pages could reveal CSRF token

Django includes both a [caching framework](#) and a system for [preventing cross-site request forgery \(CSRF\) attacks](#). The CSRF-protection system is based on a random nonce sent to the client in a cookie which must be sent by the client on future requests and, in forms, a hidden value which must be submitted back with the form.

The caching framework includes an option to cache responses to anonymous (i.e., unauthenticated) clients.

When the first anonymous request to a given page is by a client which did not have a CSRF cookie, the cache framework will also cache the CSRF cookie and serve the same nonce to other anonymous clients who do not have a CSRF cookie. This can allow an attacker to obtain a valid CSRF cookie value and perform attacks which bypass the check for the cookie.

To remedy this, the caching framework will no longer cache such responses. The heuristic for this will be:

1. If the incoming request did not submit any cookies, and
2. If the response did send one or more cookies, and
3. If the `Vary: Cookie` header is set on the response, then the response will not be cached.

MySQL typecasting

The MySQL database is known to “typecast” on certain queries; for example, when querying a table which contains string values, but using a query which filters based on an integer value, MySQL will first silently coerce the strings to integers and return a result based on that.

If a query is performed without first converting values to the appropriate type, this can produce unexpected results, similar to what would occur if the query itself had been manipulated.

Django’s model field classes are aware of their own types and most such classes perform explicit conversion of query arguments to the correct database-level type before querying. However, three model field classes did not correctly convert their arguments:

- *[FilePathField](#)*
- *[GenericIPAddressField](#)*
- `IPAddressField`

These three fields have been updated to convert their arguments to the correct types before querying.

Additionally, developers of custom model fields are now warned via documentation to ensure their custom field classes will perform appropriate type conversions, and users of the *[raw\(\)](#)* and *[extra\(\)](#)* query methods –which allow the developer to supply raw SQL or SQL fragments –will be advised to ensure they perform appropriate manual type conversions prior to executing queries.

Bugfixes

- Fixed *ModelBackend* raising `UnboundLocalError` if `get_user_model()` raised an error (#21439).

Additionally, Django's vendored version of `six`, `django.utils.six`, has been upgraded to the latest release (1.6.1).

Django 1.5.5 release notes

October 23, 2013

Django 1.5.5 fixes a couple security-related bugs and several other bugs in the 1.5 series.

Readdressed denial-of-service via password hashers

Django 1.5.4 imposes a 4096-byte limit on passwords in order to mitigate a denial-of-service attack through submission of bogus but extremely large passwords. In Django 1.5.5, we've reverted this change and instead improved the speed of our PBKDF2 algorithm by not rehashing the key on every iteration.

Properly rotate CSRF token on login

This behavior introduced as a security hardening measure in Django 1.5.2 did not work properly and is now fixed.

Bugfixes

- Fixed a data corruption bug with `datetime_safe.datetime.combine` (#21256).
- Fixed a Python 3 incompatibility in `django.utils.text.unescape_entities()` (#21185).
- Fixed a couple data corruption issues with `QuerySet` edge cases under Oracle and MySQL (#21203, #21126).
- Fixed crashes when using combinations of `annotate()`, `select_related()`, and `only()` (#16436).

Backwards incompatible changes

- The undocumented `django.core.servers.basehttp.WSGIServerException` has been removed. Use `socket.error` provided by the standard library instead.

Django 1.5.4 release notes

September 14, 2013

This is Django 1.5.4, the fourth release in the Django 1.5 series. It addresses two security issues and one bug.

Denial-of-service via password hashers

In previous versions of Django, no limit was imposed on the plaintext length of a password. This allowed a denial-of-service attack through submission of bogus but extremely large passwords, tying up server resources performing the (expensive, and increasingly expensive with the length of the password) calculation of the corresponding hash.

As of 1.5.4, Django's authentication framework imposes a 4096-byte limit on passwords, and will fail authentication with any submitted password of greater length.

Corrected usage of `sensitive_post_parameters()` in `django.contrib.auth`'s admin

The decoration of the `add_view` and `user_change_password` user admin views with `sensitive_post_parameters()` did not include `method_decorator()` (required since the views are methods) resulting in the decorator not being properly applied. This usage has been fixed and `sensitive_post_parameters()` will now throw an exception if it's improperly used.

Bugfixes

- Fixed a bug that prevented a `QuerySet` that uses `prefetch_related()` from being pickled and unpickled more than once (the second pickling attempt raised an exception) (#21102).

Django 1.5.3 release notes

September 10, 2013

This is Django 1.5.3, the third release in the Django 1.5 series. It addresses one security issue and also contains an opt-in feature to enhance the security of `django.contrib.sessions`.

Directory traversal vulnerability in ssi template tag

In previous versions of Django it was possible to bypass the `ALLOWED_INCLUDE_ROOTS` setting used for security with the `ssi` template tag by specifying a relative path that starts with one of the allowed roots. For example, if `ALLOWED_INCLUDE_ROOTS = ("/var/www",)` the following would be possible:

```
{% ssi "/var/www/../../../../etc/passwd" %}
```

In practice this is not a very common problem, as it would require the template author to put the `ssi` file in a user-controlled variable, but it's possible in principle.

Mitigating a remote-code execution vulnerability in `django.contrib.sessions`

`django.contrib.sessions` currently uses `pickle` to serialize session data before storing it in the backend. If you're using the `signed cookie session backend` and `SECRET_KEY` is known by an attacker (there isn't an inherent vulnerability in Django that would cause it to leak), the attacker could insert a string into their session which, when unpickled, executes arbitrary code on the server. The technique for doing so is simple and easily available on the internet. Although the cookie session storage signs the cookie-stored data to prevent tampering, a `SECRET_KEY` leak immediately escalates to a remote code execution vulnerability.

This attack can be mitigated by serializing session data using JSON rather than `pickle`. To facilitate this, Django 1.5.3 introduces a new setting, `SESSION_SERIALIZER`, to customize the session serialization format. For backwards compatibility, this setting defaults to using `pickle`. While JSON serialization does not support all Python objects like `pickle` does, we highly recommend switching to JSON-serialized values. Also, as JSON requires string keys, you will likely run into problems if you are using non-string keys in `request.session`. See the [Session serialization](#) documentation for more details.

Django 1.5.2 release notes

August 13, 2013

This is Django 1.5.2, a bugfix and security release for Django 1.5.

Mitigated possible XSS attack via user-supplied redirect URLs

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()`, `django.contrib.comments`, and `is18n`) to redirect the user to an “on success” URL. The security checks for these redirects (namely `django.utils.http.is_safe_url()`) didn't check if the scheme is `http(s)` and as such allowed `javascript:...` URLs to be entered. If a developer relied on `is_safe_url()` to provide safe redirect targets and put such a URL into a link, they could suffer from a XSS attack. This bug doesn't affect Django currently, since we only put this URL into the `Location` response header and browsers seem to ignore JavaScript there.

XSS vulnerability in `django.contrib.admin`

If a `URLField` is used in Django 1.5, it displays the current value of the field and a link to the target on the admin change page. The display routine of this widget was flawed and allowed for XSS.

Bugfixes

- Fixed a crash with `prefetch_related()` (#19607) as well as some `pickle` regressions with `prefetch_related` (#20157 and #20257).
- Fixed a regression in `django.contrib.gis` in the Google Map output on Python 3 (#20773).
- Made `DjangoTestSuiteRunner.setup_databases` properly handle aliases for the default database (#19940) and prevented `teardown_databases` from attempting to tear down aliases (#20681).
- Fixed the `django.core.cache.backends.memcached.MemcachedCache` backend's `get_many()` method on Python 3 (#20722).
- Fixed `django.contrib.humanize` translation syntax errors. Affected languages: Mexican Spanish, Mongolian, Romanian, Turkish (#20695).
- Added support for wheel packages (#19252).
- The CSRF token now rotates when a user logs in.
- Some Python 3 compatibility fixes including #20212 and #20025.
- Fixed some rare cases where `get()` exceptions recursed infinitely (#20278).
- `makemessages` no longer crashes with `UnicodeDecodeError` (#20354).
- Fixed `geojson` detection with `Spatialite`.
- `assertContains()` once again works with binary content (#20237).
- Fixed `ManyToManyField` if it has a `Unicode` `name` parameter (#20207).
- Ensured that the WSGI request's path is correctly based on the `SCRIPT_NAME` environment variable or the `FORCE_SCRIPT_NAME` setting, regardless of whether or not either has a trailing slash (#20169).
- Fixed an obscure bug with the `override_settings()` decorator. If you hit an `AttributeError: 'Settings' object has no attribute '_original_allowed_hosts'` exception, it's probably fixed (#20636).

Django 1.5.1 release notes

March 28, 2013

This is Django 1.5.1, a bugfix release for Django 1.5. It’s completely backwards compatible with Django 1.5, but includes a handful of fixes.

The biggest fix is for a memory leak introduced in Django 1.5. Under certain circumstances, repeated iteration over querysets could leak memory – sometimes quite a bit of it. If you’d like more information, the details are in [our ticket tracker](#) (and in [a related issue](#) in Python itself).

If you’ve noticed memory problems under Django 1.5, upgrading to 1.5.1 should fix those issues.

Django 1.5.1 also includes a couple smaller fixes:

- Module-level warnings emitted during tests are no longer silently hidden ([#18985](#)).
- Prevented filtering on password hashes in the user admin ([#20078](#)).

Django 1.5 release notes

February 26, 2013

Welcome to Django 1.5!

These release notes cover the [new features](#), as well as some [backwards incompatible changes](#) you’ll want to be aware of when upgrading from Django 1.4 or older versions. We’ve also dropped some features, which are detailed in [our deprecation plan](#), and we’ve begun the [deprecation process](#) for some features.

Overview

The biggest new feature in Django 1.5 is the [configurable User model](#). Before Django 1.5, applications that wanted to use Django’s auth framework (*[django.contrib.auth](#)*) were forced to use Django’s definition of a “user”. In Django 1.5, you can now swap out the `User` model for one that you write yourself. This could be a simple extension to the existing `User` model –for example, you could add a Twitter or Facebook ID field –or you could completely replace the `User` with one totally customized for your site.

Django 1.5 is also the first release with [Python 3 support](#)! We’re labeling this support “experimental” because we don’t yet consider it production-ready, but everything’s in place for you to start porting your apps to Python 3. Our next release, Django 1.6, will support Python 3 without reservations.

Other notable new features in Django 1.5 include:

- [Support for saving a subset of model’s fields](#) – *`Model.save()`* now accepts an `update_fields` argument, letting you specify which fields are written back to the database when you call `save()`. This can help in high-concurrency operations, and can improve performance.
- Better [support for streaming responses](#) via the new *`StreamingHttpResponse`* response class.

- [GeoDjango](#) now supports PostGIS 2.0.
- ... and more; [see below](#).

Wherever possible we try to introduce new features in a backwards-compatible manner per [our API stability policy](#). However, as with previous releases, Django 1.5 ships with some minor [backwards incompatible changes](#); people upgrading from previous versions of Django should read that list carefully.

One deprecated feature worth noting is the shift to “new-style” [url](#) tag. Prior to Django 1.3, syntax like `{% url myview %}` was interpreted incorrectly (Django considered “myview” to be a literal name of a view, not a template variable named `myview`). Django 1.3 and above introduced the `{% load url from future %}` syntax to bring in the corrected behavior where `myview` was seen as a variable.

The upshot of this is that if you are not using `{% load url from future %}` in your templates, you’ ll need to change tags like `{% url myview %}` to `{% url "myview" %}`. If you were using `{% load url from future %}` you can simply remove that line under Django 1.5

Python compatibility

Django 1.5 requires Python 2.6.5 or above, though we highly recommend Python 2.7.3 or above. Support for Python 2.5 and below has been dropped.

This change should affect only a small number of Django users, as most operating-system vendors today are shipping Python 2.6 or newer as their default version. If you’ re still using Python 2.5, however, you’ ll need to stick to Django 1.4 until you can upgrade your Python version. Per [our support policy](#), Django 1.4 will continue to receive security support until the release of Django 1.6.

Django 1.5 does not run on a Jython final release, because Jython’ s latest release doesn’ t currently support Python 2.6. However, Jython currently does offer an alpha release featuring 2.7 support, and Django 1.5 supports that alpha release.

Python 3 support

Django 1.5 introduces support for Python 3 - specifically, Python 3.2 and above. This comes in the form of a single codebase; you don’ t need to install a different version of Django on Python 3. This means that you can write applications targeted for just Python 2, just Python 3, or single applications that support both platforms.

However, we’ re labeling this support “experimental” for now: although it’ s received extensive testing via our automated test suite, it’ s received very little real-world testing. We’ ve done our best to eliminate bugs, but we can’ t be sure we covered all possible uses of Django.

Some features of Django aren’ t available because they depend on third-party software that hasn’ t been ported to Python 3 yet, including:

- the MySQL database backend (depends on MySQLdb)

- *ImageField* (depends on PIL)
- *LiveServerTestCase* (depends on Selenium WebDriver)

Further, Django's more than a web framework; it's an ecosystem of pluggable components. At this point, very few third-party applications have been ported to Python 3, so it's unlikely that a real-world application will have all its dependencies satisfied under Python 3.

Thus, we're recommending that Django 1.5 not be used in production under Python 3. Instead, use this opportunity to begin porting applications to Python 3. If you're an author of a pluggable component, we encourage you to start porting now.

We plan to offer first-class, production-ready support for Python 3 in our next release, Django 1.6.

What's new in Django 1.5

Configurable User model

In Django 1.5, you can now use your own model as the store for user-related data. If your project needs a username with more than 30 characters, or if you want to store user's names in a format other than first name/last name, or you want to put custom profile information onto your User object, you can now do so.

If you have a third-party reusable application that references the User model, you may need to make some changes to the way you reference User instances. You should also document any specific features of the User model that your application relies upon.

See the [documentation on custom user models](#) for more details.

Support for saving a subset of model's fields

The method *Model.save()* has a new keyword argument `update_fields`. By using this argument it is possible to save only a select list of model's fields. This can be useful for performance reasons or when trying to avoid overwriting concurrent changes.

Deferred instances (those loaded by `.only()` or `.defer()`) will automatically save just the loaded fields. If any field is set manually after load, that field will also get updated on save.

See the *Model.save()* documentation for more details.

Caching of related model instances

When traversing relations, the ORM will avoid re-fetching objects that were previously loaded. For example, with the tutorial's models:

```
>>> first_poll = Poll.objects.all()[0]
>>> first_choice = first_poll.choice_set.all()[0]
>>> first_choice.poll is first_poll
True
```

In Django 1.5, the third line no longer triggers a new SQL query to fetch `first_choice.poll`; it was set by the second line.

For one-to-one relationships, both sides can be cached. For many-to-one relationships, only the single side of the relationship can be cached. This is particularly helpful in combination with `prefetch_related`.

Explicit support for streaming responses

Before Django 1.5, it was possible to create a streaming response by passing an iterator to *HttpResponse*. But this was unreliable: any middleware that accessed the *content* attribute would consume the iterator prematurely.

You can now explicitly generate a streaming response with the new *StreamingHttpResponse* class. This class exposes a *streaming_content* attribute which is an iterator.

Since *StreamingHttpResponse* does not have a *content* attribute, middleware that needs access to the response content must test for streaming responses and behave accordingly.

{% verbatim %} template tag

To make it easier to deal with JavaScript templates which collide with Django's syntax, you can now use the *verbatim* block tag to avoid parsing the tag's content.

Retrieval of ContentType instances associated with proxy models

The methods *ContentTypeManager.get_for_model()* and *ContentTypeManager.get_for_models()* have a new keyword argument—respectively `for_concrete_model` and `for_concrete_models`. By passing `False` using this argument it is now possible to retrieve the *ContentType* associated with proxy models.

New view variable in class-based views context

In all [generic class-based views](#) (or any class-based view inheriting from `ContextMixin`), the context dictionary contains a `view` variable that points to the `View` instance.

GeoDjango

- `LineString` and `MultiLineString` GEOS objects now support the `interpolate()` and `project()` methods (so-called linear referencing).
- The `wkb` and `hex` properties of `GEOSGeometry` objects preserve the Z dimension.
- Support for PostGIS 2.0 has been added and support for GDAL < 1.5 has been dropped.

New tutorials

Additions to the docs include a revamped [Tutorial 3](#) and a new [tutorial on testing](#). A new section, “Advanced Tutorials”, offers [How to write reusable apps](#) as well as a step-by-step guide for new contributors in [Writing your first patch for Django](#).

Minor features

Django 1.5 also includes several smaller improvements worth noting:

- The template engine now interprets `True`, `False` and `None` as the corresponding Python objects.
- `django.utils.timezone` provides a helper for converting aware datetimes between time zones. See `localtime()`.
- The generic views support `OPTIONS` requests.
- Management commands do not raise `SystemExit` any more when called by code from `call_command()`. Any exception raised by the command (mostly `CommandError`) is propagated.

Moreover, when you output errors or messages in your custom commands, you should now use `self.stdout.write('message')` and `self.stderr.write('error')` (see the note on [management commands output](#)).

- The `dumpdata` management command outputs one row at a time, preventing out-of-memory errors when dumping large datasets.
- In the local flavor for Canada, `pq` was added to the acceptable codes for Quebec. It’s an old abbreviation.
- The `receiver` decorator is now able to connect to more than one signal by supplying a list of signals.
- In the admin, you can now filter users by groups which they are members of.

- `QuerySet.bulk_create()` now has a `batch_size` argument. By default the `batch_size` is unlimited except for SQLite where single batch is limited so that 999 parameters per query isn't exceeded.
- The `LOGIN_URL` and `LOGIN_REDIRECT_URL` settings now also accept view function names and [named URL patterns](#). This allows you to reduce configuration duplication. More information can be found in the `login_required()` documentation.
- Django now provides a `mod_wsgi` [auth handler](#).
- The `QuerySet.delete()` and `Model.delete()` can now take fast-path in some cases. The fast-path allows for less queries and less objects fetched into memory. See `QuerySet.delete()` for details.
- An instance of `ResolverMatch` is stored on the request as `resolver_match`.
- By default, all logging messages reaching the django logger when `DEBUG` is `True` are sent to the console (unless you redefine the logger in your `LOGGING` setting).
- When using `RequestContext`, it is now possible to look up permissions by using `{% if 'someapp.someperm' in perms %}` in templates.
- It's not required any more to have `404.html` and `500.html` templates in the root templates directory. Django will output some basic error messages for both situations when those templates are not found. It's still recommended as good practice to provide those templates in order to present pretty error pages to the user.
- `django.contrib.auth` provides a new signal that is emitted whenever a user fails to login successfully. See `user_login_failed`
- The new `loaddata --ignorenonexistent` option ignore data for fields that no longer exist.
- `assertXMLEqual()` and `assertXMLNotEqual()` new assertions allow you to test equality for XML content at a semantic level, without caring for syntax differences (spaces, attribute order, etc.).
- `RemoteUserMiddleware` now forces logout when the `REMOTE_USER` header disappears during the same browser session.
- The [cache-based session backend](#) can store session data in a non-default cache.
- Multi-column indexes can now be created on models. Read the [index_together](#) documentation for more information.
- During Django's logging configuration verbose Deprecation warnings are enabled and warnings are captured into the logging system. Logged warnings are routed through the `console` logging handler, which by default requires `DEBUG` to be `True` for output to be generated. The result is that Deprecation-Warnings should be printed to the console in development environments the way they have been in Python versions < 2.7.
- The API for `django.contrib.admin.ModelAdmin.message_user()` method has been modified to accept additional arguments adding capabilities similar to `django.contrib.messages.add_message()`. This is useful for generating error messages from admin actions.

- The admin’s list filters can now be customized per-request thanks to the new `django.contrib.admin.ModelAdmin.get_list_filter()` method.

Backwards incompatible changes in 1.5

Warning: In addition to the changes outlined in this section, be sure to review the [deprecation plan](#) for any features that have been removed. If you haven’t updated your code within the deprecation timeline for a given feature, its removal may appear as a backwards incompatible change.

ALLOWED_HOSTS required in production

The new `ALLOWED_HOSTS` setting validates the request’s `Host` header and protects against host-poisoning attacks. This setting is now required whenever `DEBUG` is `False`, or else `django.http.HttpRequest.get_host()` will raise `SuspiciousOperation`. For more details see the [full documentation](#) for the new setting.

Managers on abstract models

Abstract models are able to define a custom manager, and that manager [will be inherited by any concrete models extending the abstract model](#). However, if you try to use the abstract model to call a method on the manager, an exception will now be raised. Previously, the call would have been permitted, but would have failed as soon as any database operation was attempted (usually with a “table does not exist” error from the database).

If you have functionality on a manager that you have been invoking using the abstract class, you should migrate that logic to a Python `staticmethod` or `classmethod` on the abstract class.

Context in year archive class-based views

For consistency with the other date-based generic views, `YearArchiveView` now passes `year` in the context as a `datetime.date` rather than a string. If you are using `{{ year }}` in your templates, you must replace it with `{{ year|date:"Y" }}`.

`next_year` and `previous_year` were also added in the context. They are calculated according to `allow_empty` and `allow_future`.

Context in year and month archive class-based views

YearArchiveView and *MonthArchiveView* were documented to provide a `date_list` sorted in ascending order in the context, like their function-based predecessors, but it actually was in descending order. In 1.5, the documented order was restored. You may want to add (or remove) the `reversed` keyword when you're iterating on `date_list` in a template:

```
{% for date in date_list reversed %}
```

ArchiveIndexView still provides a `date_list` in descending order.

Context in TemplateView

For consistency with the design of the other generic views, *TemplateView* no longer passes a `params` dictionary into the context, instead passing the variables from the `URLconf` directly into the context.

Non-form data in HTTP requests

request.POST will no longer include data posted via HTTP requests with non form-specific content-types in the header. In prior versions, data posted with content-types other than *multipart/form-data* or *application/x-www-form-urlencoded* would still end up represented in the *request.POST* attribute. Developers wishing to access the raw POST data for these cases, should use the *request.body* attribute instead.

request_finished signal

Django used to send the *request_finished* signal as soon as the view function returned a response. This interacted badly with *streaming responses* that delay content generation.

This signal is now sent after the content is fully consumed by the WSGI gateway. This might be backwards incompatible if you rely on the signal being fired before sending the response content to the client. If you do, you should consider using *middleware* instead.

Note: Some WSGI servers and middleware do not always call `close` on the response object after handling a request, most notably uWSGI prior to 1.2.6 and Sentry's error reporting middleware up to 2.0.7. In those cases the *request_finished* signal isn't sent at all. This can result in idle connections to database and memcache servers.

OPTIONS, PUT and DELETE requests in the test client

Unlike GET and POST, these HTTP methods aren't implemented by web browsers. Rather, they're used in APIs, which transfer data in various formats such as JSON or XML. Since such requests may contain arbitrary data, Django doesn't attempt to decode their body.

However, the test client used to build a query string for OPTIONS and DELETE requests like for GET, and a request body for PUT requests like for POST. This encoding was arbitrary and inconsistent with Django's behavior when it receives the requests, so it was removed in Django 1.5.

If you were using the `data` parameter in an OPTIONS or a DELETE request, you must convert it to a query string and append it to the `path` parameter.

If you were using the `data` parameter in a PUT request without a `content_type`, you must encode your data before passing it to the test client and set the `content_type` argument.

System version of `simplejson` no longer used

As explained below, Django 1.5 deprecates `django.utils.simplejson` in favor of Python 2.6's built-in `json` module. In theory, this change is harmless. Unfortunately, because of incompatibilities between versions of `simplejson`, it may trigger errors in some circumstances.

JSON-related features in Django 1.4 always used `django.utils.simplejson`. This module was actually:

- A system version of `simplejson`, if one was available (i.e. `import simplejson` works), if it was more recent than Django's built-in copy or it had the C speedups, or
- The `json` module from the standard library, if it was available (i.e. Python 2.6 or greater), or
- A built-in copy of version 2.0.7 of `simplejson`.

In Django 1.5, those features use Python's `json` module, which is based on version 2.0.9 of `simplejson`.

There are no known incompatibilities between Django's copy of version 2.0.7 and Python's copy of version 2.0.9. However, there are some incompatibilities between other versions of `simplejson`:

- While the `simplejson` API is documented as always returning Unicode strings, the optional C implementation can return a bytestring. This was fixed in Python 2.7.
- `simplejson.JSONEncoder` gained a `namedtuple_as_object` keyword argument in version 2.2.

More information on these incompatibilities is available in [ticket #18023](#).

The net result is that, if you have installed `simplejson` and your code uses Django's serialization internals directly—for instance `django.core.serializers.json.DjangoJSONEncoder`, the switch from `simplejson` to `json` could break your code. (In general, changes to internals aren't documented; we're making an exception here.)

At this point, the maintainers of Django believe that using `json` from the standard library offers the strongest guarantee of backwards-compatibility. They recommend to use it from now on.

String types of hasher method parameters

If you have written a [custom password hasher](#), your `encode()`, `verify()` or `safe_summary()` methods should accept Unicode parameters (`password`, `salt` or `encoded`). If any of the hashing methods need bytestrings, you can use the `force_bytes()` utility to encode the strings.

Validation of `previous_page_number` and `next_page_number`

When using [object pagination](#), the `previous_page_number()` and `next_page_number()` methods of the [Page](#) object did not check if the returned number was inside the existing page range. It does check it now and raises an [InvalidPage](#) exception when the number is either too low or too high.

Behavior of autocommit database option on PostgreSQL changed

PostgreSQL's autocommit option didn't work as advertised previously. It did work for single transaction block, but after the first block was left the autocommit behavior was never restored. This bug is now fixed in 1.5. While this is only a bug fix, it is worth checking your applications behavior if you are using PostgreSQL together with the autocommit option.

Session not saved on 500 responses

Django's session middleware will skip saving the session data if the response's status code is 500.

Email checks on failed admin login

Prior to Django 1.5, if you attempted to log into the admin interface and mistakenly used your email address instead of your username, the admin interface would provide a warning advising that your email address was not your username. In Django 1.5, the introduction of [custom user models](#) has required the removal of this warning. This doesn't change the login behavior of the admin site; it only affects the warning message that is displayed under one particular mode of login failure.

Changes in tests execution

Some changes have been introduced in the execution of tests that might be backward-incompatible for some testing setups:

Database flushing in `django.test.TransactionTestCase`

Previously, the test database was truncated before each test run in a *TransactionTestCase*.

In order to be able to run unit tests in any order and to make sure they are always isolated from each other, *TransactionTestCase* will now reset the database after each test run instead.

No more implicit DB sequences reset

TransactionTestCase tests used to reset primary key sequences automatically together with the database flushing actions described above.

This has been changed so no sequences are implicitly reset. This can cause *TransactionTestCase* tests that depend on hard-coded primary key values to break.

The new *reset_sequences* attribute can be used to force the old behavior for *TransactionTestCase* that might need it.

Ordering of tests

In order to make sure all `TestCase` code starts with a clean database, tests are now executed in the following order:

- First, all unit tests (including `unittest.TestCase`, *SimpleTestCase*, *TestCase* and *TransactionTestCase*) are run with no particular ordering guaranteed nor enforced among them.
- Then any other tests (e.g. doctests) that may alter the database without restoring it to its original state are run.

This should not cause any problems unless you have existing doctests which assume a *TransactionTestCase* executed earlier left some database state behind or unit tests that rely on some form of state being preserved after the execution of other tests. Such tests are already very fragile, and must now be changed to be able to run independently.

`cleaned_data` dictionary kept for invalid forms

The *cleaned_data* dictionary is now always present after form validation. When the form doesn't validate, it contains only the fields that passed validation. You should test the success of the validation with the *is_valid()* method and not with the presence or absence of the *cleaned_data* attribute on the form.

Behavior of `syncdb` with multiple databases

`syncdb` now queries the database routers to determine if content types (when `contenttypes` is enabled) and permissions (when `auth` is enabled) should be created in the target database. Previously, it created them in the default database, even when another database was specified with the `--database` option.

If you use `syncdb` on multiple databases, you should ensure that your routers allow synchronizing content types and permissions to only one of them. See the docs on the [behavior of contrib apps with multiple databases](#) for more information.

XML deserializer will not parse documents with a DTD

In order to prevent exposure to denial-of-service attacks related to external entity references and entity expansion, the XML model deserializer now refuses to parse XML documents containing a DTD (DOCTYPE definition). Since the XML serializer does not output a DTD, this will not impact typical usage, only cases where custom-created XML documents are passed to Django's model deserializer.

Formsets default `max_num`

A (default) value of `None` for the `max_num` argument to a formset factory no longer defaults to allowing any number of forms in the formset. Instead, in order to prevent memory-exhaustion attacks, it now defaults to a limit of 1000 forms. This limit can be raised by explicitly setting a higher value for `max_num`.

Miscellaneous

- `django.forms.ModelMultipleChoiceField` now returns an empty `QuerySet` as the empty value instead of an empty list.
- `int_to_base36()` properly raises a `TypeError` instead of `ValueError` for non-integer inputs.
- The `slugify` template filter is now available as a standard Python function at `django.utils.text.slugify()`. Similarly, `remove_tags` is available at `django.utils.html.remove_tags()`.
- Uploaded files are no longer created as executable by default. If you need them to be executable change `FILE_UPLOAD_PERMISSIONS` to your needs. The new default value is `0o666` (octal) and the current `umask` value is first masked out.
- The `F` *expressions* supported bitwise operators by `&` and `|`. These operators are now available using `.bitand()` and `.bitor()` instead. The removal of `&` and `|` was done to be consistent with `Q()` *expressions* and `QuerySet` combining where the operators are used as boolean AND and OR operators.
- In a `filter()` call, when `F` *expressions* contained lookups spanning multi-valued relations, they didn't always reuse the same relations as other lookups along the same chain. This was changed, and now `F()` *expressions* will always use the same relations as other lookups within the same `filter()` call.

- The `csrf_token` template tag is no longer enclosed in a `div`. If you need HTML validation against pre-HTML5 Strict DTDs, you should add a `div` around it in your pages.
- The template tags library `adminmedia`, which only contained the deprecated template tag `{% admin_media_prefix %}`, was removed. Attempting to load it with `{% load adminmedia %}` will fail. If your templates still contain that line you must remove it.
- Because of an implementation oversight, it was possible to use `django.contrib.redirects` without enabling `django.contrib.sites`. This isn't allowed any longer. If you're using `django.contrib.redirects`, make sure `INSTALLED_APPS` contains `django.contrib.sites`.
- `BoundField.label_tag` now escapes its `contents` argument. To avoid the HTML escaping, use `django.utils.safestring.mark_safe()` on the argument before passing it.
- Accessing reverse one-to-one relations fetched via `select_related()` now raises `DoesNotExist` instead of returning `None`.

Features deprecated in 1.5

`django.contrib.localflavor`

The `localflavor` contrib app has been split into separate packages. `django.contrib.localflavor` itself will be removed in Django 1.6, after an accelerated deprecation.

The new packages are available on GitHub. The core team cannot efficiently maintain these packages in the long term—it spans just a dozen countries at this time; similar to translations, maintenance will be handed over to interested members of the community.

`django.contrib.markup`

The `markup` contrib module has been deprecated and will follow an accelerated deprecation schedule. Direct use of Python markup libraries or 3rd party tag libraries is preferred to Django maintaining this functionality in the framework.

`AUTH_PROFILE_MODULE`

With the introduction of [custom user models](#), there is no longer any need for a built-in mechanism to store user profile data.

You can still define user profiles models that have a one-to-one relation with the `User` model - in fact, for many applications needing to associate data with a `User` account, this will be an appropriate design pattern to follow. However, the `AUTH_PROFILE_MODULE` setting, and the `django.contrib.auth.models.User.get_profile()` method for accessing the user profile model, should not be used any longer.

Streaming behavior of `HttpResponse`

Django 1.5 deprecates the ability to stream a response by passing an iterator to `HttpResponse`. If you rely on this behavior, switch to `StreamingHttpResponse`. See [Explicit support for streaming responses](#) above.

In Django 1.7 and above, the iterator will be consumed immediately by `HttpResponse`.

`django.utils.simplejson`

Since Django 1.5 drops support for Python 2.5, we can now rely on the `json` module being available in Python's standard library, so we've removed our own copy of `simplejson`. You should now import `json` instead of `django.utils.simplejson`.

Unfortunately, this change might have unwanted side-effects, because of incompatibilities between versions of `simplejson` –see the [backwards-incompatible changes](#) section. If you rely on features added to `simplejson` after it became Python's `json`, you should import `simplejson` explicitly.

`django.utils.encoding.StrAndUnicode`

The `django.utils.encoding.StrAndUnicode` mix-in has been deprecated. Define a `__str__` method and apply the `django.utils.encoding.python_2_unicode_compatible` decorator instead.

`django.utils.itercompat.product`

The `django.utils.itercompat.product` function has been deprecated. Use the built-in `itertools.product()` instead.

cleanup management command

The `cleanup` management command has been deprecated and replaced by `clearsessions`.

`daily_cleanup.py` script

The undocumented `daily_cleanup.py` script has been deprecated. Use the `clearsessions` management command instead.

depth keyword argument in `select_related`

The `depth` keyword argument in `select_related()` has been deprecated. You should use field names instead.

9.1.17 1.4 release

Django 1.4.22 release notes

August 18, 2015

Django 1.4.22 fixes a security issue in 1.4.21.

It also fixes support with pip 7+ by disabling wheel support. Older versions of 1.4 would silently build a broken wheel when installed with those versions of pip.

Denial-of-service possibility in `logout()` view by filling session store

Previously, a session could be created when anonymously accessing the `django.contrib.auth.views.logout()` view (provided it wasn't decorated with `login_required()` as done in the admin). This could allow an attacker to easily create many new session records by sending repeated requests, potentially filling up the session store or causing other users' session records to be evicted.

The `SessionMiddleware` has been modified to no longer create empty session records, including when `SESSION_SAVE_EVERY_REQUEST` is active.

Additionally, the `contrib.sessions.backends.base.SessionBase.flush()` and `cache_db.SessionStore.flush()` methods have been modified to avoid creating a new empty session. Maintainers of third-party session backends should check if the same vulnerability is present in their backend and correct it if so.

Django 1.4.21 release notes

July 8, 2015

Django 1.4.21 fixes several security issues in 1.4.20.

Denial-of-service possibility by filling session store

In previous versions of Django, the session backends created a new empty record in the session storage any-time `request.session` was accessed and there was a session key provided in the request cookies that didn't already have a session record. This could allow an attacker to easily create many new session records simply by sending repeated requests with unknown session keys, potentially filling up the session store or causing other users' session records to be evicted.

The built-in session backends now create a session record only if the session is actually modified; empty session records are not created. Thus this potential DoS is now only possible if the site chooses to expose a session-modifying view to anonymous users.

As each built-in session backend was fixed separately (rather than a fix in the core sessions framework), maintainers of third-party session backends should check whether the same vulnerability is present in their backend and correct it if so.

Header injection possibility since validators accept newlines in input

Some of Django's built-in validators (*EmailValidator*, most seriously) didn't prohibit newline characters (due to the usage of `$` instead of `\Z` in the regular expressions). If you use values with newlines in HTTP response or email headers, you can suffer from header injection attacks. Django itself isn't vulnerable because *HttpResponse* and the mail sending utilities in *django.core.mail* prohibit newlines in HTTP and SMTP headers, respectively. While the validators have been fixed in Django, if you're creating HTTP responses or email messages in other ways, it's a good idea to ensure that those methods prohibit newlines as well. You might also want to validate that any existing data in your application doesn't contain unexpected newlines.

validate_ipv4_address(), *validate_slug()*, and *URLValidator* and their usage in the corresponding form fields *GenericIPAddressField*, *IPAddressField*, *SlugField*, and *URLField* are also affected.

The undocumented, internally unused *validate_integer()* function is now stricter as it validates using a regular expression instead of simply casting the value using *int()* and checking if an exception was raised.

Django 1.4.20 release notes

March 18, 2015

Django 1.4.20 fixes one security issue in 1.4.19.

Mitigated possible XSS attack via user-supplied redirect URLs

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()` and [i18n](#)) to redirect the user to an “on success” URL. The security checks for these redirects (namely `django.utils.http.is_safe_url()`) accepted URLs with leading control characters and so considered URLs like `\x08javascript:... safe`. This issue doesn’t affect Django currently, since we only put this URL into the `Location` response header and browsers seem to ignore JavaScript there. Browsers we tested also treat URLs prefixed with control characters such as `%08//example.com` as relative paths so redirection to an unsafe target isn’t a problem either.

However, if a developer relies on `is_safe_url()` to provide safe redirect targets and puts such a URL into a link, they could suffer from an XSS attack as some browsers such as Google Chrome ignore control characters at the start of a URL in an anchor `href`.

Django 1.4.19 release notes

January 27, 2015

Django 1.4.19 fixes a regression in the 1.4.18 security release.

Bugfixes

- `GZipMiddleware` now supports streaming responses. As part of the 1.4.18 security release, the `django.views.static.serve()` function was altered to stream the files it serves. Unfortunately, the `GZipMiddleware` consumed the stream prematurely and prevented files from being served properly ([#24158](#)).

Django 1.4.18 release notes

January 13, 2015

Django 1.4.18 fixes several security issues in 1.4.17 as well as a regression on Python 2.5 in the 1.4.17 release.

WSGI header spoofing via underscore/dash conflation

When HTTP headers are placed into the WSGI environ, they are normalized by converting to uppercase, converting all dashes to underscores, and prepending `HTTP_`. For instance, a header `X-Auth-User` would become `HTTP_X_AUTH_USER` in the WSGI environ (and thus also in Django’s `request.META` dictionary).

Unfortunately, this means that the WSGI environ cannot distinguish between headers containing dashes and headers containing underscores: `X-Auth-User` and `X-Auth_User` both become `HTTP_X_AUTH_USER`. This means that if a header is used in a security-sensitive way (for instance, passing authentication information

along from a front-end proxy), even if the proxy carefully strips any incoming value for `X-Auth-User`, an attacker may be able to provide an `X-Auth_User` header (with underscore) and bypass this protection.

In order to prevent such attacks, both Nginx and Apache 2.4+ strip all headers containing underscores from incoming requests by default. Django's built-in development server now does the same. Django's development server is not recommended for production use, but matching the behavior of common production servers reduces the surface area for behavior changes during deployment.

Mitigated possible XSS attack via user-supplied redirect URLs

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()` and [i18n](#)) to redirect the user to an “on success” URL. The security checks for these redirects (namely `django.utils.http.is_safe_url()`) didn't strip leading whitespace on the tested URL and as such considered URLs like `\njavascript:... safe`. If a developer relied on `is_safe_url()` to provide safe redirect targets and put such a URL into a link, they could suffer from a XSS attack. This bug doesn't affect Django currently, since we only put this URL into the `Location` response header and browsers seem to ignore JavaScript there.

Denial-of-service attack against `django.views.static.serve`

In older versions of Django, the `django.views.static.serve()` view read the files it served one line at a time. Therefore, a big file with no newlines would result in memory usage equal to the size of that file. An attacker could exploit this and launch a denial-of-service attack by simultaneously requesting many large files. This view now reads the file in chunks to prevent large memory usage.

Note, however, that this view has always carried a warning that it is not hardened for production use and should be used only as a development aid. Now may be a good time to audit your project and serve your files in production using a real front-end web server if you are not doing so.

Bugfixes

- To maintain compatibility with Python 2.5, Django's vendored version of `six`, `django.utils.six`, has been downgraded to 1.8.0 which is the last version to support Python 2.5.

Django 1.4.17 release notes

January 2, 2015

Django 1.4.17 fixes a regression in the 1.4.14 security release.

Additionally, Django's vendored version of `six`, `django.utils.six`, has been upgraded to the latest release (1.9.0).

Bugfixes

- Fixed a regression with dynamically generated inlines and allowed field references in the admin ([#23754](#)).

Django 1.4.16 release notes

October 22, 2014

Django 1.4.16 fixes a couple regressions in the 1.4.14 security release and a bug preventing the use of some GEOS versions with GeoDjango.

Bugfixes

- Allowed related many-to-many fields to be referenced in the admin ([#23604](#)).
- Allowed inline and hidden references to admin fields ([#23431](#)).
- Fixed parsing of the GEOS version string ([#20036](#)).

Django 1.4.15 release notes

September 2, 2014

Django 1.4.15 fixes a regression in the 1.4.14 security release.

Bugfixes

- Allowed inherited and m2m fields to be referenced in the admin ([#22486](#))

Django 1.4.14 release notes

August 20, 2014

Django 1.4.14 fixes several security issues in 1.4.13.

`reverse()` could generate URLs pointing to other hosts

In certain situations, URL reversing could generate scheme-relative URLs (URLs starting with two slashes), which could unexpectedly redirect a user to a different host. An attacker could exploit this, for example, by redirecting users to a phishing site designed to ask for user's passwords.

To remedy this, URL reversing now ensures that no URL starts with two slashes (`//`), replacing the second slash with its URL encoded counterpart (`%2F`). This approach ensures that semantics stay the same, while making the URL relative to the domain and not to the scheme.

File upload denial-of-service

Before this release, Django's file upload handling in its default configuration may degrade to producing a huge number of `os.stat()` system calls when a duplicate filename is uploaded. Since `stat()` may invoke IO, this may produce a huge data-dependent slowdown that slowly worsens over time. The net result is that given enough time, a user with the ability to upload files can cause poor performance in the upload handler, eventually causing it to become very slow simply by uploading 0-byte files. At this point, even a slow network connection and few HTTP requests would be all that is necessary to make a site unavailable.

We've remedied the issue by changing the algorithm for generating file names if a file with the uploaded name already exists. `Storage.get_available_name()` now appends an underscore plus a random 7 character alphanumeric string (e.g. `"_x3a1gho"`), rather than iterating through an underscore followed by a number (e.g. `"_1"`, `"_2"`, etc.).

RemoteUserMiddleware session hijacking

When using the `RemoteUserMiddleware` and the `RemoteUserBackend`, a change to the `REMOTE_USER` header between requests without an intervening logout could result in the prior user's session being co-opted by the subsequent user. The middleware now logs the user out on a failed login attempt.

Data leakage via query string manipulation in `contrib.admin`

In older versions of Django it was possible to reveal any field's data by modifying the "popup" and "to_field" parameters of the query string on an admin change form page. For example, requesting a URL like `/admin/auth/user/?pop=1&t=password` and viewing the page's HTML allowed viewing the password hash of each user. While the admin requires users to have permissions to view the change form pages in the first place, this could leak data if you rely on users having access to view only certain fields on a model.

To address the issue, an exception will now be raised if a `to_field` value that isn't a related field to a model that has been registered with the admin is specified.

Django 1.4.13 release notes

May 14, 2014

Django 1.4.13 fixes two security issues in 1.4.12.

Caches may incorrectly be allowed to store and serve private data

In certain situations, Django may allow caches to store private data related to a particular session and then serve that data to requests with a different session, or no session at all. This can lead to information disclosure and can be a vector for cache poisoning.

When using Django sessions, Django will set a `Vary: Cookie` header to ensure caches do not serve cached data to requests from other sessions. However, older versions of Internet Explorer (most likely only Internet Explorer 6, and Internet Explorer 7 if run on Windows XP or Windows Server 2003) are unable to handle the `Vary` header in combination with many content types. Therefore, Django would remove the header if the request was made by Internet Explorer.

To remedy this, the special behavior for these older Internet Explorer versions has been removed, and the `Vary` header is no longer stripped from the response. In addition, modifications to the `Cache-Control` header for all Internet Explorer requests with a `Content-Disposition` header have also been removed as they were found to have similar issues.

Malformed redirect URLs from user input not correctly validated

The validation for redirects did not correctly validate some malformed URLs, which are accepted by some browsers. This allows a user to be redirected to an unsafe URL unexpectedly.

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()`, `django.contrib.comments`, and `il8n`) to redirect the user to an “on success” URL. The security checks for these redirects (namely `django.utils.http.is_safe_url()`) did not correctly validate some malformed URLs, such as `http:\\\\\\\\djangoproject.com`, which are accepted by some browsers with more liberal URL parsing.

To remedy this, the validation in `is_safe_url()` has been tightened to be able to handle and correctly validate these malformed URLs.

Django 1.4.12 release notes

April 28, 2014

Django 1.4.12 fixes a regression in the 1.4.11 security release.

Bugfixes

- Restored the ability to `reverse()` views created using `functools.partial()` (#22486).

Django 1.4.11 release notes

April 21, 2014

Django 1.4.11 fixes three security issues in 1.4.10. Additionally, Django’s vendored version of six, `django.utils.six`, has been upgraded to the latest release (1.6.1).

Unexpected code execution using `reverse()`

Django’s URL handling is based on a mapping of regex patterns (representing the URLs) to callable views, and Django’s own processing consists of matching a requested URL against those patterns to determine the appropriate view to invoke.

Django also provides a convenience function –`reverse()`–which performs this process in the opposite direction. The `reverse()` function takes information about a view and returns a URL which would invoke that view. Use of `reverse()` is encouraged for application developers, as the output of `reverse()` is always based on the current URL patterns, meaning developers do not need to change other code when making changes to URLs.

One argument signature for `reverse()` is to pass a dotted Python path to the desired view. In this situation, Django will import the module indicated by that dotted path as part of generating the resulting URL. If such a module has import-time side effects, those side effects will occur.

Thus it is possible for an attacker to cause unexpected code execution, given the following conditions:

1. One or more views are present which construct a URL based on user input (commonly, a “next” parameter in a querystring indicating where to redirect upon successful completion of an action).
2. One or more modules are known to an attacker to exist on the server’s Python import path, which perform code execution with side effects on importing.

To remedy this, `reverse()` will now only accept and import dotted paths based on the view-containing modules listed in the project’s [URL pattern configuration](#), so as to ensure that only modules the developer intended to be imported in this fashion can or will be imported.

Caching of anonymous pages could reveal CSRF token

Django includes both a [caching framework](#) and a system for [preventing cross-site request forgery \(CSRF\) attacks](#). The CSRF-protection system is based on a random nonce sent to the client in a cookie which must be sent by the client on future requests and, in forms, a hidden value which must be submitted back with the form.

The caching framework includes an option to cache responses to anonymous (i.e., unauthenticated) clients.

When the first anonymous request to a given page is by a client which did not have a CSRF cookie, the cache framework will also cache the CSRF cookie and serve the same nonce to other anonymous clients who do not have a CSRF cookie. This can allow an attacker to obtain a valid CSRF cookie value and perform attacks which bypass the check for the cookie.

To remedy this, the caching framework will no longer cache such responses. The heuristic for this will be:

1. If the incoming request did not submit any cookies, and
2. If the response did send one or more cookies, and
3. If the `Vary: Cookie` header is set on the response, then the response will not be cached.

MySQL typecasting

The MySQL database is known to “typecast” on certain queries; for example, when querying a table which contains string values, but using a query which filters based on an integer value, MySQL will first silently coerce the strings to integers and return a result based on that.

If a query is performed without first converting values to the appropriate type, this can produce unexpected results, similar to what would occur if the query itself had been manipulated.

Django’s model field classes are aware of their own types and most such classes perform explicit conversion of query arguments to the correct database-level type before querying. However, three model field classes did not correctly convert their arguments:

- *`FilePathField`*
- *`GenericIPAddressField`*
- `IPAddressField`

These three fields have been updated to convert their arguments to the correct types before querying.

Additionally, developers of custom model fields are now warned via documentation to ensure their custom field classes will perform appropriate type conversions, and users of the *`raw()`* and *`extra()`* query methods –which allow the developer to supply raw SQL or SQL fragments –will be advised to ensure they perform appropriate manual type conversions prior to executing queries.

Django 1.4.10 release notes

November 6, 2013

Django 1.4.10 fixes a Python-compatibility bug in the 1.4 series.

Python compatibility

Django 1.4.9 inadvertently introduced issues with Python 2.5 compatibility. Django 1.4.10 restores Python 2.5 compatibility. This was issue #21362 in Django's Trac.

Django 1.4.9 release notes

October 23, 2013

Django 1.4.9 fixes a security-related bug in the 1.4 series and one other data corruption bug.

Readdressed denial-of-service via password hashers

Django 1.4.8 imposes a 4096-byte limit on passwords in order to mitigate a denial-of-service attack through submission of bogus but extremely large passwords. In Django 1.4.9, we've reverted this change and instead improved the speed of our PBKDF2 algorithm by not rehashing the key on every iteration.

Bugfixes

- Fixed a data corruption bug with `datetime_safe.datetime.combine` (#21256).

Django 1.4.8 release notes

September 14, 2013

Django 1.4.8 fixes two security issues present in previous Django releases in the 1.4 series.

Denial-of-service via password hashers

In previous versions of Django, no limit was imposed on the plaintext length of a password. This allowed a denial-of-service attack through submission of bogus but extremely large passwords, tying up server resources performing the (expensive, and increasingly expensive with the length of the password) calculation of the corresponding hash.

As of 1.4.8, Django's authentication framework imposes a 4096-byte limit on passwords and will fail authentication with any submitted password of greater length.

Corrected usage of `sensitive_post_parameters()` in `django.contrib.auth`'s admin

The decoration of the `add_view` and `user_change_password` user admin views with `sensitive_post_parameters()` did not include `method_decorator()` (required since the views are methods) resulting in the decorator not being properly applied. This usage has been fixed and `sensitive_post_parameters()` will now throw an exception if it's improperly used.

Django 1.4.7 release notes

September 10, 2013

Django 1.4.7 fixes one security issue present in previous Django releases in the 1.4 series.

Directory traversal vulnerability in `ssi` template tag

In previous versions of Django it was possible to bypass the `ALLOWED_INCLUDE_ROOTS` setting used for security with the `ssi` template tag by specifying a relative path that starts with one of the allowed roots. For example, if `ALLOWED_INCLUDE_ROOTS = ("/var/www",)` the following would be possible:

```
{% ssi "/var/www/../../../../etc/passwd" %}
```

In practice this is not a very common problem, as it would require the template author to put the `ssi` file in a user-controlled variable, but it's possible in principle.

Django 1.4.6 release notes

August 13, 2013

Django 1.4.6 fixes one security issue present in previous Django releases in the 1.4 series, as well as one other bug.

This is the sixth bugfix/security release in the Django 1.4 series.

Mitigated possible XSS attack via user-supplied redirect URLs

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()`, `django.contrib.comments`, and `i18n`) to redirect the user to an “on success” URL. The security checks for these redirects (namely `django.utils.http.is_safe_url()`) didn't check if the scheme is `http(s)` and as such allowed `javascript:...` URLs to be entered. If a developer relied on `is_safe_url()` to provide safe redirect targets and put such a URL into a link, they could suffer from a XSS attack. This bug doesn't affect Django currently, since we only put this URL into the `Location` response header and browsers seem to ignore JavaScript there.

Bugfixes

- Fixed an obscure bug with the `override_settings()` decorator. If you hit an `AttributeError: 'Settings' object has no attribute '_original_allowed_hosts'` exception, it's probably fixed (#20636).

Django 1.4.5 release notes

February 20, 2013

Django 1.4.5 corrects a packaging problem with yesterday's [1.4.4 release](#).

The release contained stray `.pyc` files that caused “bad magic number” errors when running with some versions of Python. This release corrects this, and also fixes a bad documentation link in the project template `settings.py` file generated by `manage.py startproject`.

Django 1.4.4 release notes

February 19, 2013

Django 1.4.4 fixes four security issues present in previous Django releases in the 1.4 series, as well as several other bugs and numerous documentation improvements.

This is the fourth bugfix/security release in the Django 1.4 series.

Host header poisoning

Some parts of Django –independent of end-user-written applications– make use of full URLs, including domain name, which are generated from the HTTP Host header. Django's documentation has for some time contained notes advising users on how to configure web servers to ensure that only valid Host headers can reach the Django application. However, it has been reported to us that even with the recommended web server configurations there are still techniques available for tricking many common web servers into supplying the application with an incorrect and possibly malicious Host header.

For this reason, Django 1.4.4 adds a new setting, `ALLOWED_HOSTS`, containing an explicit list of valid host/domain names for this site. A request with a Host header not matching an entry in this list will raise `SuspiciousOperation` if `request.get_host()` is called. For full details see the documentation for the [ALLOWED_HOSTS](#) setting.

The default value for this setting in Django 1.4.4 is `['*']` (matching any host), for backwards-compatibility, but we strongly encourage all sites to set a more restrictive value.

This host validation is disabled when `DEBUG` is `True` or when running tests.

XML deserialization

The XML parser in the Python standard library is vulnerable to a number of attacks via external entities and entity expansion. Django uses this parser for deserializing XML-formatted database fixtures. This deserializer is not intended for use with untrusted data, but in order to err on the side of safety in Django 1.4.4 the XML deserializer refuses to parse an XML document with a DTD (DOCTYPE definition), which closes off these attack avenues.

These issues in the Python standard library are CVE-2013-1664 and CVE-2013-1665. More information available [from the Python security team](#).

Django's XML serializer does not create documents with a DTD, so this should not cause any issues with the typical round-trip from `dumpdata` to `loaddata`, but if you feed your own XML documents to the `loaddata` management command, you will need to ensure they do not contain a DTD.

Formset memory exhaustion

Previous versions of Django did not validate or limit the form-count data provided by the client in a formset's management form, making it possible to exhaust a server's available memory by forcing it to create very large numbers of forms.

In Django 1.4.4, all formsets have a strictly-enforced maximum number of forms (1000 by default, though it can be set higher via the `max_num` formset factory argument).

Admin history view information leakage

In previous versions of Django, an admin user without change permission on a model could still view the Unicode representation of instances via their admin history log. Django 1.4.4 now limits the admin history log view for an object to users with change permission for that model.

Other bugfixes and changes

- Prevented transaction state from leaking from one request to the next (#19707).
- Changed an SQL command syntax to be MySQL 4 compatible (#19702).
- Added backwards-compatibility with old unsalted MD5 passwords (#18144).
- Numerous documentation improvements and fixes.

Django 1.4.3 release notes

December 10, 2012

Django 1.4.3 addresses two security issues present in previous Django releases in the 1.4 series.

Please be aware that this security release is slightly different from previous ones. Both issues addressed here have been dealt with in prior security updates to Django. In one case, we have received ongoing reports of problems, and in the other we've chosen to take further steps to tighten up Django's code in response to independent discovery of potential problems from multiple sources.

Host header poisoning

Several earlier Django security releases focused on the issue of poisoning the HTTP Host header, causing Django to generate URLs pointing to arbitrary, potentially-malicious domains.

In response to further input received and reports of continuing issues following the previous release, we're taking additional steps to tighten Host header validation. Rather than attempt to accommodate all features HTTP supports here, Django's Host header validation attempts to support a smaller, but far more common, subset:

- Hostnames must consist of characters [A-Za-z0-9] plus hyphen ('-') or dot ('.').
- IP addresses –both IPv4 and IPv6 –are permitted.
- Port, if specified, is numeric.

Any deviation from this will now be rejected, raising the exception `django.core.exceptions.SuspiciousOperation`.

Redirect poisoning

Also following up on a previous issue: in July of this year, we made changes to Django's HTTP redirect classes, performing additional validation of the scheme of the URL to redirect to (since, both within Django's own supplied applications and many third-party applications, accepting a user-supplied redirect target is a common pattern).

Since then, two independent audits of the code turned up further potential problems. So, similar to the Host-header issue, we are taking steps to provide tighter validation in response to reported problems (primarily with third-party applications, but to a certain extent also within Django itself). This comes in two parts:

1. A new utility function, `django.utils.http.is_safe_url`, is added; this function takes a URL and a hostname, and checks that the URL is either relative, or if absolute matches the supplied hostname. This function is intended for use whenever user-supplied redirect targets are accepted, to ensure that such redirects cannot lead to arbitrary third-party sites.

2. All of Django's own built-in views –primarily in the authentication system –which allow user-supplied redirect targets now use `is_safe_url` to validate the supplied URL.

Django 1.4.2 release notes

October 17, 2012

This is the second security release in the Django 1.4 series.

Host header poisoning

Some parts of Django –independent of end-user-written applications –make use of full URLs, including domain name, which are generated from the HTTP Host header. Some attacks against this are beyond Django's ability to control, and require the web server to be properly configured; Django's documentation has for some time contained notes advising users on such configuration.

Django's own built-in parsing of the Host header is, however, still vulnerable, as was reported to us recently. The Host header parsing in Django 1.3.3 and Django 1.4.1 –specifically, `django.http.HttpRequest.get_host()` –was incorrectly handling username/password information in the header. Thus, for example, the following Host header would be accepted by Django when running on `validsite.com`:

```
Host: validsite.com:random@evilsite.com
```

Using this, an attacker can cause parts of Django –particularly the password-reset mechanism –to generate and display arbitrary URLs to users.

To remedy this, the parsing in `HttpRequest.get_host()` is being modified; Host headers which contain potentially dangerous content (such as username/password pairs) now raise the exception `django.core.exceptions.SuspiciousOperation`.

Details of this issue were initially posted online as a [security advisory](#).

Backwards incompatible changes

- The newly introduced `GenericIPAddressField` constructor arguments have been adapted to match those of all other model fields. The first two keyword arguments are now `verbose_name` and `name`.

Other bugfixes and changes

- Subclass `HTMLParser` only for appropriate Python versions (#18239).
- Added `batch_size` argument to `qs.bulk_create()` (#17788).
- Fixed a small regression in the admin filters where wrongly formatted dates passed as url parameters caused an unhandled `ValidationError` (#18530).
- Fixed an endless loop bug when accessing permissions in templates (#18979)
- Fixed some Python 2.5 compatibility issues
- Fixed an issue with quoted filenames in Content-Disposition header (#19006)
- Made the context option in `trans` and `blocktrans` tags accept literals wrapped in single quotes (#18881).
- Numerous documentation improvements and fixes.

Django 1.4.1 release notes

July 30, 2012

This is the first security release in the Django 1.4 series, fixing several security issues in Django 1.4. Django 1.4.1 is a recommended upgrade for all users of Django 1.4.

For a full list of issues addressed in this release, see the [security advisory](#).

Django 1.4 release notes

March 23, 2012

Welcome to Django 1.4!

These release notes cover the [new features](#), as well as some [backwards incompatible changes](#) you'll want to be aware of when upgrading from Django 1.3 or older versions. We've also dropped some features, which are detailed in our [deprecation plan](#), and we've begun the [deprecation process](#) for some features.

Overview

The biggest new feature in Django 1.4 is [support for time zones](#) when handling date/times. When enabled, this Django will store date/times in UTC, use timezone-aware objects internally, and translate them to users' local timezones for display.

If you're upgrading an existing project to Django 1.4, switching to the timezone aware mode may take some care: the new mode disallows some rather sloppy behavior that used to be accepted. We encourage anyone who's upgrading to check out the [timezone migration guide](#) and the [timezone FAQ](#) for useful pointers.

Other notable new features in Django 1.4 include:

- A number of ORM improvements, including [SELECT FOR UPDATE support](#), the ability to [bulk insert](#) large datasets for improved performance, and `QuerySet.prefetch_related`, a method to batch-load related objects in areas where `select_related()` doesn't work.
- Some nice security additions, including [improved password hashing](#) (featuring PBKDF2 and `bcrypt` support), new [tools for cryptographic signing](#), several CSRF improvements, and [simple clickjacking protection](#).
- An [updated default project layout](#) and `manage.py` that removes the “magic” from prior versions. And for those who don't like the new layout, you can use [custom project and app templates](#) instead!
- [Support for in-browser testing frameworks](#) (like Selenium).
- ... and a whole lot more; [see below!](#)

Wherever possible we try to introduce new features in a backwards-compatible manner per [our API stability policy](#). However, as with previous releases, Django 1.4 ships with some minor [backwards incompatible changes](#); people upgrading from previous versions of Django should read that list carefully.

Python compatibility

Django 1.4 has dropped support for Python 2.4. Python 2.5 is now the minimum required Python version. Django is tested and supported on Python 2.5, 2.6 and 2.7.

This change should affect only a small number of Django users, as most operating-system vendors today are shipping Python 2.5 or newer as their default version. If you're still using Python 2.4, however, you'll need to stick to Django 1.3 until you can upgrade. Per [our support policy](#), Django 1.3 will continue to receive security support until the release of Django 1.5.

Django does not support Python 3.x at this time. At some point before the release of Django 1.4, we plan to publish a document outlining our full timeline for deprecating Python 2.x and moving to Python 3.x.

What's new in Django 1.4

Support for time zones

In previous versions, Django used “naive” date/times (that is, date/times without an associated time zone), leaving it up to each developer to interpret what a given date/time “really means”. This can cause all sorts of subtle timezone-related bugs.

In Django 1.4, you can now switch Django into a more correct, time-zone aware mode. In this mode, Django stores date and time information in UTC in the database, uses time-zone-aware datetime objects internally and translates them to the end user's time zone in templates and forms. Reasons for using this feature include:

- Customizing date and time display for users around the world.
- Storing datetimes in UTC for database portability and interoperability. (This argument doesn't apply to PostgreSQL, because it already stores timestamps with time zone information in Django 1.3.)
- Avoiding data corruption problems around DST transitions.

Time zone support is enabled by default in new projects created with `startproject`. If you want to use this feature in an existing project, read the [migration guide](#). If you encounter problems, there's a helpful [FAQ](#).

Support for in-browser testing frameworks

Django 1.4 supports integration with in-browser testing frameworks like [Selenium](#). The new `django.test.LiveServerTestCase` base class lets you test the interactions between your site's front and back ends more comprehensively. See the [documentation](#) for more details and concrete examples.

Updated default project layout and `manage.py`

Django 1.4 ships with an updated default project layout and `manage.py` file for the `startproject` management command. These fix some issues with the previous `manage.py` handling of Python import paths that caused double imports, trouble moving from development to deployment, and other difficult-to-debug path issues.

The previous `manage.py` called functions that are now deprecated, and thus projects upgrading to Django 1.4 should update their `manage.py`. (The old-style `manage.py` will continue to work as before until Django 1.6. In 1.5 it will raise `DeprecationWarning`).

The new recommended `manage.py` file should look like this:

```
#!/usr/bin/env python
import os, sys

if __name__ == "__main__":
    os.environ.setdefault("DJANGO_SETTINGS_MODULE", "{ project_name }.settings")

    from django.core.management import execute_from_command_line

    execute_from_command_line(sys.argv)
```

`{ project_name }` should be replaced with the Python package name of the actual project.

If settings, URLconfs and apps within the project are imported or referenced using the project name prefix (e.g. `myproject.settings`, `ROOT_URLCONF = "myproject.urls"`, etc.), the new `manage.py` will need to be moved one directory up, so it is outside the project package rather than adjacent to `settings.py` and `urls.py`.

For instance, with the following layout:

```
manage.py
mysite/
    __init__.py
    settings.py
    urls.py
    myapp/
        __init__.py
        models.py
```

You could import `mysite.settings`, `mysite.urls`, and `mysite.myapp`, but not `settings`, `urls`, or `myapp` as top-level modules.

Anything imported as a top-level module can be placed adjacent to the new `manage.py`. For instance, to decouple `myapp` from the project module and import it as just `myapp`, place it outside the `mysite/` directory:

```
manage.py
myapp/
    __init__.py
    models.py
mysite/
    __init__.py
    settings.py
    urls.py
```

If the same code is imported inconsistently (some places with the project prefix, some places without it), the imports will need to be cleaned up when switching to the new `manage.py`.

Custom project and app templates

The `startapp` and `startproject` management commands now have a `--template` option for specifying a path or URL to a custom app or project template.

For example, Django will use the `/path/to/my_project_template` directory when you run the following command:

```
django-admin.py startproject --template=/path/to/my_project_template myproject
```

You can also now provide a destination directory as the second argument to both `startapp` and `startproject`:

```
django-admin.py startapp myapp /path/to/new/app
django-admin.py startproject myproject /path/to/new/project
```

For more information, see the `startapp` and `startproject` documentation.

Improved WSGI support

The `startproject` management command now adds a `wsgi.py` module to the initial project layout, containing a simple WSGI application that can be used for [deploying with WSGI app servers](#).

The `built-in development server` now supports using an externally-defined WSGI callable, which makes it possible to run `runserver` with the same WSGI configuration that is used for deployment. The new `WSGI_APPLICATION` setting lets you configure which WSGI callable `runserver` uses.

(The `runfcgi` management command also internally wraps the WSGI callable configured via `WSGI_APPLICATION`.)

SELECT FOR UPDATE support

Django 1.4 includes a `QuerySet.select_for_update()` method, which generates a `SELECT ... FOR UPDATE` SQL query. This will lock rows until the end of the transaction, meaning other transactions cannot modify or delete rows matched by a `FOR UPDATE` query.

For more details, see the documentation for `select_for_update()`.

`Model.objects.bulk_create` in the ORM

This method lets you create multiple objects more efficiently. It can result in significant performance increases if you have many objects.

Django makes use of this internally, meaning some operations (such as database setup for test suites) have seen a performance benefit as a result.

See the `bulk_create()` docs for more information.

`QuerySet.prefetch_related`

Similar to `select_related()` but with a different strategy and broader scope, `prefetch_related()` has been added to `QuerySet`. This method returns a new `QuerySet` that will prefetch each of the specified related lookups in a single batch as soon as the query begins to be evaluated. Unlike `select_related`, it does the joins in Python, not in the database, and supports many-to-many relationships, `GenericForeignKey` and more. This allows you to fix a very common performance problem in which your code ends up doing $O(n)$ database queries (or worse) if objects on your primary `QuerySet` each have many related objects that you also need to fetch.

Improved password hashing

Django’s auth system (`django.contrib.auth`) stores passwords using a one-way algorithm. Django 1.3 uses the [SHA1](#) algorithm, but increasing processor speeds and theoretical attacks have revealed that SHA1 isn’t as secure as we’d like. Thus, Django 1.4 introduces a new password storage system: by default Django now uses the [PBKDF2](#) algorithm (as recommended by [NIST](#)). You can also easily choose a different algorithm (including the popular [bcrypt](#) algorithm). For more details, see [How Django stores passwords](#).

HTML5 doctype

We’ve switched the admin and other bundled templates to use the HTML5 doctype. While Django will be careful to maintain compatibility with older browsers, this change means that you can use any HTML5 features you need in admin pages without having to lose HTML validity or override the provided templates to change the doctype.

List filters in admin interface

Prior to Django 1.4, the `admin` app let you specify change list filters by specifying a field lookup, but it didn’t allow you to create custom filters. This has been rectified with a simple API (previously used internally and known as “FilterSpec”). For more details, see the documentation for `list_filter`.

Multiple sort in admin interface

The admin change list now supports sorting on multiple columns. It respects all elements of the `ordering` attribute, and sorting on multiple columns by clicking on headers is designed to mimic the behavior of desktop GUIs. We also added a `get_ordering()` method for specifying the ordering dynamically (i.e., depending on the request).

New `ModelAdmin` methods

We added a `save_related()` method to `ModelAdmin` to ease customization of how related objects are saved in the admin.

Two other new `ModelAdmin` methods, `get_list_display()` and `get_list_display_links()` enable dynamic customization of fields and links displayed on the admin change list.

Admin inlines respect user permissions

Admin inlines now only allow those actions for which the user has permission. For `ManyToMany` relationships with an auto-created intermediate model (which does not have its own permissions), the change permission for the related model determines if the user has the permission to add, change or delete relationships.

Tools for cryptographic signing

Django 1.4 adds both a low-level API for signing values and a high-level API for setting and reading signed cookies, one of the most common uses of signing in web applications.

See the [cryptographic signing](#) docs for more information.

Cookie-based session backend

Django 1.4 introduces a cookie-based session backend that uses the tools for [cryptographic signing](#) to store the session data in the client's browser.

Warning: Session data is signed and validated by the server, but it's not encrypted. This means a user can view any data stored in the session but cannot change it. Please read the documentation for further clarification before using this backend.

See the [cookie-based session backend](#) docs for more information.

New form wizard

The previous `FormWizard` from `django.contrib.formtools` has been replaced with a new implementation based on the class-based views introduced in Django 1.3. It features a pluggable storage API and doesn't require the wizard to pass around hidden fields for every previous step.

Django 1.4 ships with a session-based storage backend and a cookie-based storage backend. The latter uses the tools for [cryptographic signing](#) also introduced in Django 1.4 to store the wizard's state in the user's cookies.

`reverse_lazy`

A lazily evaluated version of `reverse()` was added to allow using URL reversals before the project's `URLconf` gets loaded.

Translating URL patterns

Django can now look for a language prefix in the `URLpattern` when using the new `isn_patterns()` helper function. It's also now possible to define translatable URL patterns using `django.utils.translation.ugettext_lazy()`. See [Internationalization: in URL patterns](#) for more information about the language prefix and how to internationalize URL patterns.

Contextual translation support for `{% trans %}` and `{% blocktrans %}`

The [contextual translation](#) support introduced in Django 1.3 via the `pgettext` function has been extended to the `trans` and `blocktrans` template tags using the new `context` keyword.

Customizable `SingleObjectMixin` `URLConf` kwargs

Two new attributes, `pk_url_kwarg` and `slug_url_kwarg`, have been added to `SingleObjectMixin` to enable the customization of `URLconf` keyword arguments used for single object generic views.

Assignment template tags

A new `assignment_tag` helper function was added to `template.Library` to ease the creation of template tags that store data in a specified context variable.

`*args` and `**kwargs` support for template tag helper functions

The `simple_tag`, `inclusion_tag` and newly introduced `assignment_tag` template helper functions may now accept any number of positional or keyword arguments. For example:

```
@register.simple_tag
def my_tag(a, b, *args, **kwargs):
    warning = kwargs["warning"]
    profile = kwargs["profile"]
    ...
    return ...
```

Then, in the template, any number of arguments may be passed to the template tag. For example:

```
{% my_tag 123 "abcd" book.title warning=message|lower profile=user.profile %}
```

No wrapping of exceptions in `TEMPLATE_DEBUG` mode

In previous versions of Django, whenever the `TEMPLATE_DEBUG` setting was `True`, any exception raised during template rendering (even exceptions unrelated to template syntax) were wrapped in `TemplateSyntaxError` and re-raised. This was done in order to provide detailed template source location information in the debug 500 page.

In Django 1.4, exceptions are no longer wrapped. Instead, the original exception is annotated with the source information. This means that catching exceptions from template rendering is now consistent regardless of the value of `TEMPLATE_DEBUG`, and there's no need to catch and unwrap `TemplateSyntaxError` in order to catch other errors.

`truncatechars` template filter

This new filter truncates a string to be no longer than the specified number of characters. Truncated strings end with a translatable ellipsis sequence (`" ... "`). See the documentation for [truncatechars](#) for more details.

static template tag

The `staticfiles` contrib app has a new `static` template tag to refer to files saved with the `STATICFILES_STORAGE` storage backend. It uses the storage backend's `url` method and therefore supports advanced features such as serving files from a cloud service.

CachedStaticFilesStorage storage backend

The `staticfiles` contrib app now has a `django.contrib.staticfiles.storage.CachedStaticFilesStorage` backend that caches the files it saves (when running the `collectstatic` management command) by appending the MD5 hash of the file's content to the filename. For example, the file `css/styles.css` would also be saved as `css/styles.55e7cbb9ba48.css`

Simple clickjacking protection

We've added a middleware to provide easy protection against [clickjacking](#) using the `X-Frame-Options` header. It's not enabled by default for backwards compatibility reasons, but you'll almost certainly want to [enable it](#) to help plug that security hole for browsers that support the header.

CSRF improvements

We've made various improvements to our CSRF features, including the `ensure_csrf_cookie()` decorator, which can help with AJAX-heavy sites; protection for PUT and DELETE requests; and the `CSRF_COOKIE_SECURE` and `CSRF_COOKIE_PATH` settings, which can improve the security and usefulness of CSRF protection. See the [CSRF docs](#) for more information.

Error report filtering

We added two function decorators, `sensitive_variables()` and `sensitive_post_parameters()`, to allow designating the local variables and POST parameters that may contain sensitive information and should be filtered out of error reports.

All POST parameters are now systematically filtered out of error reports for certain views (`login`, `password_reset_confirm`, `password_change` and `add_view` in `django.contrib.auth.views`, as well as `user_change_password` in the admin app) to prevent the leaking of sensitive information such as user passwords.

You can override or customize the default filtering by writing a [custom filter](#). For more information see the docs on [Filtering error reports](#).

Extended IPv6 support

Django 1.4 can now better handle IPv6 addresses with the new `GenericIPAddressField` model field, `GenericIPAddressField` form field and the validators `validate_ipv46_address` and `validate_ipv6_address`.

HTML comparisons in tests

The base classes in `django.test` now have some helpers to compare HTML without tripping over irrelevant differences in whitespace, argument quoting/ordering and closing of self-closing tags. You can either compare HTML directly with the new `assertHTMLEqual()` and `assertHTMLNotEqual()` assertions, or use the `html=True` flag with `assertContains()` and `assertNotContains()` to test whether the client's response contains a given HTML fragment. See the [assertions documentation](#) for more.

Two new date format strings

Two new *date* formats were added for use in template filters, template tags and [Format localization](#):

- *e* –the name of the timezone of the given datetime object
- *o* –the ISO 8601 year number

Please make sure to update your [custom format files](#) if they contain either *e* or *o* in a format string. For example a Spanish localization format previously only escaped the *d* format character:

```
DATE_FORMAT = r"j \de F \de Y"
```

But now it needs to also escape *e* and *o*:

```
DATE_FORMAT = r"j \d\e F \d\e Y"
```

For more information, see the [date](#) documentation.

Minor features

Django 1.4 also includes several smaller improvements worth noting:

- A more usable stacktrace in the technical 500 page. Frames in the stack trace that reference Django's framework code are dimmed out, while frames in application code are slightly emphasized. This change makes it easier to scan a stacktrace for issues in application code.
- [Tablespace support](#) in PostgreSQL.
- Customizable names for *simple_tag()*.
- In the documentation, a helpful [security overview](#) page.
- The `django.contrib.auth.models.check_password` function has been moved to the `django.contrib.auth.hashers` module. Importing it from the old location will still work, but you should update your imports.
- The *collectstatic* management command now has a `--clear` option to delete all files at the destination before copying or linking the static files.
- It's now possible to load fixtures containing forward references when using MySQL with the InnoDB database engine.
- A new 403 response handler has been added as `'django.views.defaults.permission_denied'`. You can set your own handler by setting the value of `django.conf.urls.handler403`. See the documentation about [the 403 \(HTTP Forbidden\) view](#) for more information.
- The *makemessages* command uses a new and more accurate lexer, *JsLex*, for extracting translatable strings from JavaScript files.

- The `trans` template tag now takes an optional `as` argument to be able to retrieve a translation string without displaying it but setting a template context variable instead.
- The `if` template tag now supports `{% elif %}` clauses.
- If your Django app is behind a proxy, you might find the new `SECURE_PROXY_SSL_HEADER` setting useful. It solves the problem of your proxy “eating” the fact that a request came in via HTTPS. But only use this setting if you know what you’re doing.
- A new, plain-text, version of the HTTP 500 status code internal error page served when `DEBUG` is `True` is now sent to the client when Django detects that the request has originated in JavaScript code. (`is_ajax()` is used for this.)

Like its HTML counterpart, it contains a collection of different pieces of information about the state of the application.

This should make it easier to read when debugging interaction with client-side JavaScript.

- Added the `makemessages --no-location` option.
- Changed the `locmem` cache backend to use `pickle.HIGHEST_PROTOCOL` for better compatibility with the other cache backends.
- Added support in the ORM for generating `SELECT` queries containing `DISTINCT ON`.

The `distinct()` `QuerySet` method now accepts an optional list of model field names. If specified, then the `DISTINCT` statement is limited to these fields. This is only supported in PostgreSQL.

For more details, see the documentation for `distinct()`.

- The admin login page will add a password reset link if you include a URL with the name `'admin_password_reset'` in your `urls.py`, so plugging in the built-in password reset mechanism and making it available is now much easier. For details, see [Adding a password reset feature](#).
- The MySQL database backend can now make use of the savepoint feature implemented by MySQL version 5.0.3 or newer with the InnoDB storage engine.
- It’s now possible to pass initial values to the model forms that are part of both model formsets and inline model formsets as returned from factory functions `modelformset_factory` and `inlineformset_factory` respectively just like with regular formsets. However, initial values only apply to extra forms, i.e. those which are not bound to an existing model instance.
- The sitemaps framework can now handle HTTPS links using the new `Sitemap.protocol` class attribute.
- A new `django.test.SimpleTestCase` subclass of `unittest.TestCase` that’s lighter than `django.test.TestCase` and company. It can be useful in tests that don’t need to hit a database. See [Hierarchy of Django unit testing classes](#).

Backwards incompatible changes in 1.4

`SECRET_KEY` setting is required

Running Django with an empty or known `SECRET_KEY` disables many of Django's security protections and can lead to remote-code-execution vulnerabilities. No Django site should ever be run without a `SECRET_KEY`.

In Django 1.4, starting Django with an empty `SECRET_KEY` will raise a `DeprecationWarning`. In Django 1.5, it will raise an exception and Django will refuse to start. This is slightly accelerated from the usual deprecation path due to the severity of the consequences of running Django with no `SECRET_KEY`.

`django.contrib.admin`

The included administration app `django.contrib.admin` has for a long time shipped with a default set of static files such as JavaScript, images and stylesheets. Django 1.3 added a new contrib app `django.contrib.staticfiles` to handle such files in a generic way and defined conventions for static files included in apps.

Starting in Django 1.4, the admin's static files also follow this convention, to make the files easier to deploy. In previous versions of Django, it was also common to define an `ADMIN_MEDIA_PREFIX` setting to point to the URL where the admin's static files live on a web server. This setting has now been deprecated and replaced by the more general setting `STATIC_URL`. Django will now expect to find the admin static files under the URL `<STATIC_URL>/admin/`.

If you've previously used a URL path for `ADMIN_MEDIA_PREFIX` (e.g. `/media/`) simply make sure `STATIC_URL` and `STATIC_ROOT` are configured and your web server serves those files correctly. The development server continues to serve the admin files just like before. Read the [static files howto](#) for more details.

If your `ADMIN_MEDIA_PREFIX` is set to a specific domain (e.g. `http://media.example.com/admin/`), make sure to also set your `STATIC_URL` setting to the correct URL –for example, `http://media.example.com/`.

Warning: If you're implicitly relying on the path of the admin static files within Django's source code, you'll need to update that path. The files were moved from `django/contrib/admin/media/` to `django/contrib/admin/static/admin/`.

Supported browsers for the admin

Django hasn't had a clear policy on which browsers are supported by the admin app. Our new policy formalizes existing practices: YUI's A-grade browsers should provide a fully-functional admin experience, with the notable exception of Internet Explorer 6, which is no longer supported.

Released over 10 years ago, IE6 imposes many limitations on modern web development. The practical implications of this policy are that contributors are free to improve the admin without consideration for these limitations.

This new policy has no impact on sites you develop using Django. It only applies to the Django admin. Feel free to develop apps compatible with any range of browsers.

Removed admin icons

As part of an effort to improve the performance and usability of the admin’s change-list sorting interface and *horizontal* and *vertical* “filter” widgets, some icon files were removed and grouped into two sprite files.

Specifically: `selector-add.gif`, `selector-addall.gif`, `selector-remove.gif`, `selector-removeall.gif`, `selector_stacked-add.gif` and `selector_stacked-remove.gif` were combined into `selector-icons.gif`; and `arrow-up.gif` and `arrow-down.gif` were combined into `sorting-icons.gif`.

If you used those icons to customize the admin, then you’ll need to replace them with your own icons or get the files from a previous release.

CSS class names in admin forms

To avoid conflicts with other common CSS class names (e.g. “button”), we added a prefix (“field-”) to all CSS class names automatically generated from the form field names in the main admin forms, stacked inline forms and tabular inline cells. You’ll need to take that prefix into account in your custom style sheets or JavaScript files if you previously used plain field names as selectors for custom styles or JavaScript transformations.

Compatibility with old signed data

Django 1.3 changed the cryptographic signing mechanisms used in a number of places in Django. While Django 1.3 kept fallbacks that would accept hashes produced by the previous methods, these fallbacks are removed in Django 1.4.

So, if you upgrade to Django 1.4 directly from 1.2 or earlier, you may lose/invalidate certain pieces of data that have been cryptographically signed using an old method. To avoid this, use Django 1.3 first for a period of time to allow the signed data to expire naturally. The affected parts are detailed below, with 1) the consequences of ignoring this advice and 2) the amount of time you need to run Django 1.3 for the data to expire or become irrelevant.

- `contrib.sessions` data integrity check
 - Consequences: The user will be logged out, and session data will be lost.
 - Time period: Defined by `SESSION_COOKIE_AGE`.
- `contrib.auth` password reset hash
 - Consequences: Password reset links from before the upgrade will not work.

- Time period: Defined by `PASSWORD_RESET_TIMEOUT_DAYS`.

Form-related hashes: these have a much shorter lifetime and are relevant only for the short window where a user might fill in a form generated by the pre-upgrade Django instance and try to submit it to the upgraded Django instance:

- `contrib.comments` form security hash
 - Consequences: The user will see the validation error “Security hash failed.”
 - Time period: The amount of time you expect users to take filling out comment forms.
- `FormWizard` security hash
 - Consequences: The user will see an error about the form having expired and will be sent back to the first page of the wizard, losing the data entered so far.
 - Time period: The amount of time you expect users to take filling out the affected forms.
- CSRF check
 - Note: This is actually a Django 1.1 fallback, not Django 1.2, and it applies only if you’re upgrading from 1.1.
 - Consequences: The user will see a 403 error with any CSRF-protected POST form.
 - Time period: The amount of time you expect user to take filling out such forms.
- `contrib.auth` user password hash-upgrade sequence
 - Consequences: Each user’s password will be updated to a stronger password hash when it’s written to the database in 1.4. This means that if you upgrade to 1.4 and then need to downgrade to 1.3, version 1.3 won’t be able to read the updated passwords.
 - Remedy: Set `PASSWORD_HASHERS` to use your original password hashing when you initially upgrade to 1.4. After you confirm your app works well with Django 1.4 and you won’t have to roll back to 1.3, enable the new password hashes.

`django.contrib.flatpages`

Starting in 1.4, the `FlatpageFallbackMiddleware` only adds a trailing slash and redirects if the resulting URL refers to an existing flatpage. For example, requesting `/notaflatpageoravalidurl` in a previous version would redirect to `/notaflatpageoravalidurl/`, which would subsequently raise a 404. Requesting `/notaflatpageoravalidurl` now will immediately raise a 404.

Also, redirects returned by flatpages are now permanent (with 301 status code), to match the behavior of `CommonMiddleware`.

Serialization of datetime and time

As a consequence of time-zone support, and according to the ECMA-262 specification, we made changes to the JSON serializer:

- It includes the time zone for aware datetime objects. It raises an exception for aware time objects.
- It includes milliseconds for datetime and time objects. There is still some precision loss, because Python stores microseconds (6 digits) and JSON only supports milliseconds (3 digits). However, it's better than discarding microseconds entirely.

We changed the XML serializer to use the ISO8601 format for datetimes. The letter T is used to separate the date part from the time part, instead of a space. Time zone information is included in the `[+-]HH:MM` format.

Though the serializers now use these new formats when creating fixtures, they can still load fixtures that use the old format.

supports_timezone changed to False for SQLite

The database feature `supports_timezone` used to be `True` for SQLite. Indeed, if you saved an aware datetime object, SQLite stored a string that included an UTC offset. However, this offset was ignored when loading the value back from the database, which could corrupt the data.

In the context of time-zone support, this flag was changed to `False`, and datetimes are now stored without time-zone information in SQLite. When `USE_TZ` is `False`, if you attempt to save an aware datetime object, Django raises an exception.

MySQLdb-specific exceptions

The MySQL backend historically has raised `MySQLdb.OperationalError` when a query triggered an exception. We've fixed this bug, and we now raise `django.db.DatabaseError` instead. If you were testing for `MySQLdb.OperationalError`, you'll need to update your `except` clauses.

Database connection's thread-locality

`DatabaseWrapper` objects (i.e. the connection objects referenced by `django.db.connection` and `django.db.connections["some_alias"]`) used to be thread-local. They are now global objects in order to be potentially shared between multiple threads. While the individual connection objects are now global, the `django.db.connections` dictionary referencing those objects is still thread-local. Therefore if you just use the ORM or `DatabaseWrapper.cursor()` then the behavior is still the same as before. Note, however, that `django.db.connection` does not directly reference the default `DatabaseWrapper` object anymore and is now a proxy to access that object's attributes. If you need to access the actual `DatabaseWrapper` object, use `django.db.connections[DEFAULT_DB_ALIAS]` instead.

As part of this change, all underlying SQLite connections are now enabled for potential thread-sharing (by passing the `check_same_thread=False` attribute to `pysqlite`). `DatabaseWrapper` however preserves the previous behavior by disabling thread-sharing by default, so this does not affect any existing code that purely relies on the ORM or on `DatabaseWrapper.cursor()`.

Finally, while it's now possible to pass connections between threads, Django doesn't make any effort to synchronize access to the underlying backend. Concurrency behavior is defined by the underlying backend implementation. Check their documentation for details.

`COMMENTS_BANNED_USERS_GROUP` setting

Django's comments has historically supported excluding the comments of a special user group, but we've never documented the feature properly and didn't enforce the exclusion in other parts of the app such as the template tags. To fix this problem, we removed the code from the feed class.

If you rely on the feature and want to restore the old behavior, use a custom comment model manager to exclude the user group, like this:

```
from django.conf import settings
from django.contrib.comments.managers import CommentManager

class BanningCommentManager(CommentManager):
    def get_query_set(self):
        qs = super().get_query_set()
        if getattr(settings, "COMMENTS_BANNED_USERS_GROUP", None):
            where = [
                "user_id NOT IN (SELECT user_id FROM auth_user_groups WHERE group_id = %s)"
            ]
            params = [settings.COMMENTS_BANNED_USERS_GROUP]
            qs = qs.extra(where=where, params=params)
        return qs
```

Save this model manager in your custom comment app (e.g., in `my_comments_app/managers.py`) and add it your custom comment app model:

```
from django.db import models
from django.contrib.comments.models import Comment

from my_comments_app.managers import BanningCommentManager

class CommentWithTitle(Comment):
    title = models.CharField(max_length=300)
```

(continues on next page)

(continued from previous page)

```
objects = BanningCommentManager()
```

IGNORABLE_404_STARTS and IGNORABLE_404_ENDS settings

Until Django 1.3, it was possible to exclude some URLs from Django's [404 error reporting](#) by adding prefixes to `IGNORABLE_404_STARTS` and suffixes to `IGNORABLE_404_ENDS`.

In Django 1.4, these two settings are superseded by [`IGNORABLE\_404\_URLS`](#), which is a list of compiled regular expressions. Django won't send an email for 404 errors on URLs that match any of them.

Furthermore, the previous settings had some rather arbitrary default values:

```
IGNORABLE_404_STARTS = ("/cgi-bin/", "/_vti_bin", "/_vti_inf")
IGNORABLE_404_ENDS = (
    "mail.pl",
    "mailform.pl",
    "mail.cgi",
    "mailform.cgi",
    "favicon.ico",
    ".php",
)
```

It's not Django's role to decide if your website has a legacy `/cgi-bin/` section or a `favicon.ico`. As a consequence, the default values of [`IGNORABLE\_404\_URLS`](#), `IGNORABLE_404_STARTS`, and `IGNORABLE_404_ENDS` are all now empty.

If you have customized `IGNORABLE_404_STARTS` or `IGNORABLE_404_ENDS`, or if you want to keep the old default value, you should add the following lines in your settings file:

```
import re

IGNORABLE_404_URLS = (
    # for each <prefix> in IGNORABLE_404_STARTS
    re.compile(r"^(<prefix>)",
    # for each <suffix> in IGNORABLE_404_ENDS
    re.compile(r"<suffix>$"),
)
```

Don't forget to escape characters that have a special meaning in a regular expression, such as periods.

CSRF protection extended to PUT and DELETE

Previously, Django's [CSRF protection](#) provided protection only against POST requests. Since use of PUT and DELETE methods in AJAX applications is becoming more common, we now protect all methods not defined as safe by [RFC 2616](#) –i.e., we exempt GET, HEAD, OPTIONS and TRACE, and we enforce protection on everything else.

If you're using PUT or DELETE methods in AJAX applications, please see the [instructions about using AJAX and CSRF](#).

Password reset view now accepts `subject_template_name`

The `password_reset` view in `django.contrib.auth` now accepts a `subject_template_name` parameter, which is passed to the password save form as a keyword argument. If you are using this view with a custom password reset form, then you will need to ensure your form's `save()` method accepts this keyword argument.

`django.core.template_loaders`

This was an alias to `django.template.loader` since 2005, and we've removed it without emitting a warning due to the length of the deprecation. If your code still referenced this, please use `django.template.loader` instead.

`django.db.models.fields.URLField.verify_exists`

This functionality has been removed due to intractable performance and security issues. Any existing usage of `verify_exists` should be removed.

`django.core.files.storage.Storage.open`

The `open` method of the base `Storage` class used to take an obscure parameter `mixin` that allowed you to dynamically change the base classes of the returned file object. This has been removed. In the rare case you relied on the `mixin` parameter, you can easily achieve the same by overriding the `open` method, like this:

```
from django.core.files import File
from django.core.files.storage import FileSystemStorage

class Spam(File):
    """
    Spam, spam, spam, spam and spam.
```

(continues on next page)

(continued from previous page)

```
"""

def ham(self):
    return "eggs"

class SpamStorage(FileSystemStorage):
    """
    A custom file storage backend.
    """

    def open(self, name, mode="rb"):
        return Spam(open(self.path(name), mode))
```

YAML deserializer now uses `yaml.safe_load`

`yaml.load` is able to construct any Python object, which may trigger arbitrary code execution if you process a YAML document that comes from an untrusted source. This feature isn't necessary for Django's YAML deserializer, whose primary use is to load fixtures consisting of simple objects. Even though fixtures are trusted data, the YAML deserializer now uses `yaml.safe_load` for additional security.

Session cookies now have the `httponly` flag by default

Session cookies now include the `httponly` attribute by default to help reduce the impact of potential XSS attacks. As a consequence of this change, session cookie data, including `sessionid`, is no longer accessible from JavaScript in many browsers. For strict backwards compatibility, use `SESSION_COOKIE_HTTPONLY = False` in your settings file.

The `urlize` filter no longer escapes every URL

When a URL contains a `%xx` sequence, where `xx` are two hexadecimal digits, `urlize` now assumes that the URL is already escaped and doesn't apply URL escaping again. This is wrong for URLs whose unquoted form contains a `%xx` sequence, but such URLs are very unlikely to happen in the wild, because they would confuse browsers too.

`assertTemplateUsed` and `assertTemplateNotUsed` as context manager

It's now possible to check whether a template was used within a block of code with `assertTemplateUsed()` and `assertTemplateNotUsed()`. And they can be used as a context manager:

```
with self.assertTemplateUsed("index.html"):
    render_to_string("index.html")
with self.assertTemplateNotUsed("base.html"):
    render_to_string("index.html")
```

See the [assertion documentation](#) for more.

Database connections after running the test suite

The default test runner no longer restores the database connections after tests' execution. This prevents the production database from being exposed to potential threads that would still be running and attempting to create new connections.

If your code relied on connections to the production database being created after tests' execution, then you can restore the previous behavior by subclassing `DjangoTestRunner` and overriding its `teardown_databases()` method.

Output of `manage.py help`

`manage.py help` now groups available commands by application. If you depended on the output of this command—if you parsed it, for example—then you'll need to update your code. To get a list of all available management commands in a script, use `manage.py help --commands` instead.

`extends` template tag

Previously, the `extends` tag used a buggy method of parsing arguments, which could lead to it erroneously considering an argument as a string literal when it wasn't. It now uses `parser.compile_filter`, like other tags.

The internals of the tag aren't part of the official stable API, but in the interests of full disclosure, the `ExtendsNode.__init__` definition has changed, which may break any custom tags that use this class.

Loading some incomplete fixtures no longer works

Prior to 1.4, a default value was inserted for fixture objects that were missing a specific date or datetime value when `auto_now` or `auto_now_add` was set for the field. This was something that should not have worked, and in 1.4 loading such incomplete fixtures will fail. Because fixtures are a raw import, they should explicitly specify all field values, regardless of field options on the model.

Development Server Multithreading

The development server is now is multithreaded by default. Use the `runserver --nothreading` option to disable the use of threading in the development server:

```
django-admin.py runserver --nothreading
```

Attributes disabled in markdown when safe mode set

Prior to Django 1.4, attributes were included in any markdown output regardless of safe mode setting of the filter. With version > 2.1 of the Python-Markdown library, an `enable_attributes` option was added. When the `safe` argument is passed to the markdown filter, both the `safe_mode=True` and `enable_attributes=False` options are set. If using a version of the Python-Markdown library less than 2.1, a warning is issued that the output is insecure.

FormMixin `get_initial` returns an instance-specific dictionary

In Django 1.3, the `get_initial` method of the `django.views.generic.edit.FormMixin` class was returning the class `initial` dictionary. This has been fixed to return a copy of this dictionary, so form instances can modify their initial data without messing with the class variable.

Features deprecated in 1.4

Old styles of calling `cache_page` decorator

Some legacy ways of calling `cache_page()` have been deprecated. Please see the documentation for the correct way to use this decorator.

Support for PostgreSQL versions older than 8.2

Django 1.3 dropped support for PostgreSQL versions older than 8.0, and we suggested using a more recent version because of performance improvements and, more importantly, the end of upstream support periods for 8.0 and 8.1 was near (November 2010).

Django 1.4 takes that policy further and sets 8.2 as the minimum PostgreSQL version it officially supports.

Request exceptions are now always logged

When we added [logging support](#) in Django in 1.3, the admin error email support was moved into the `django.utils.log.AdminEmailHandler`, attached to the `'django.request'` logger. In order to maintain the established behavior of error emails, the `'django.request'` logger was called only when `DEBUG` was `False`.

To increase the flexibility of error logging for requests, the `'django.request'` logger is now called regardless of the value of `DEBUG`, and the default settings file for new projects now includes a separate filter attached to `django.utils.log.AdminEmailHandler` to prevent admin error emails in `DEBUG` mode:

```
LOGGING = {
    # ...
    "filters": {
        "require_debug_false": {
            "()": "django.utils.log.RequireDebugFalse",
        },
    },
    "handlers": {
        "mail_admins": {
            "level": "ERROR",
            "filters": ["require_debug_false"],
            "class": "django.utils.log.AdminEmailHandler",
        },
    },
}
```

If your project was created prior to this change, your `LOGGING` setting will not include this new filter. In order to maintain backwards-compatibility, Django will detect that your `'mail_admins'` handler configuration includes no `'filters'` section and will automatically add this filter for you and issue a pending-deprecation warning. This will become a deprecation warning in Django 1.5, and in Django 1.6 the backwards-compatibility shim will be removed entirely.

The existence of any `'filters'` key under the `'mail_admins'` handler will disable this backward-compatibility shim and deprecation warning.

`django.conf.urls.defaults`

Until Django 1.3, the `include()`, `patterns()`, and `url()` functions, plus `handler404` and `handler500` were located in a `django.conf.urls.defaults` module.

In Django 1.4, they live in `django.conf.urls`.

`django.contrib.databrowse`

Databrowse has not seen active development for some time, and this does not show any sign of changing. There had been a suggestion for a [GSOC project](#) to integrate the functionality of databrowse into the admin, but no progress was made. While Databrowse has been deprecated, an enhancement of `django.contrib.admin` providing a similar feature set is still possible.

The code that powers Databrowse is licensed under the same terms as Django itself, so it's available to be adopted by an individual or group as a third-party project.

`django.core.management.setup_environ`

This function temporarily modified `sys.path` in order to make the parent “project” directory importable under the old flat `startproject` layout. This function is now deprecated, as its path workarounds are no longer needed with the new `manage.py` and default project layout.

This function was never documented or part of the public API, but it was widely recommended for use in setting up a “Django environment” for a user script. These uses should be replaced by setting the `DJANGO_SETTINGS_MODULE` environment variable or using `django.conf.settings.configure()`.

`django.core.management.execute_manager`

This function was previously used by `manage.py` to execute a management command. It is identical to `django.core.management.execute_from_command_line`, except that it first calls `setup_environ`, which is now deprecated. As such, `execute_manager` is also deprecated; `execute_from_command_line` can be used instead. Neither of these functions is documented as part of the public API, but a deprecation path is needed due to use in existing `manage.py` files.

`is_safe` and `needs_autoescape` attributes of template filters

Two flags, `is_safe` and `needs_autoescape`, define how each template filter interacts with Django's auto-escaping behavior. They used to be attributes of the filter function:

```
@register.filter
def noop(value):
    return value

noop.is_safe = True
```

However, this technique caused some problems in combination with decorators, especially *@stringfilter*. Now, the flags are keyword arguments of *@register.filter*:

```
@register.filter(is_safe=True)
def noop(value):
    return value
```

See [filters and auto-escaping](#) for more information.

Wildcard expansion of application names in `INSTALLED_APPS`

Until Django 1.3, *INSTALLED_APPS* accepted wildcards in application names, like `django.contrib.*`. The expansion was performed by a filesystem-based implementation of `from <package> import *`. Unfortunately, this can't be done reliably.

This behavior was never documented. Since it is unpythonic, it was removed in Django 1.4. If you relied on it, you must edit your settings file to list all your applications explicitly.

`HttpRequest.raw_post_data` renamed to `HttpRequest.body`

This attribute was confusingly named `HttpRequest.raw_post_data`, but it actually provided the body of the HTTP request. It's been renamed to `HttpRequest.body`, and `HttpRequest.raw_post_data` has been deprecated.

`django.contrib.sitemaps` bug fix with potential performance implications

In previous versions, `Paginator` objects used in sitemap classes were cached, which could result in stale site maps. We've removed the caching, so each request to a site map now creates a new `Paginator` object and calls the `items()` method of the `Sitemap` subclass. Depending on what your `items()` method is doing, this may have a negative performance impact. To mitigate the performance impact, consider using the [caching framework](#) within your `Sitemap` subclass.

Versions of Python-Markdown earlier than 2.1

Versions of Python-Markdown earlier than 2.1 do not support the option to disable attributes. As a security issue, earlier versions of this library will not be supported by the markup contrib app in 1.5 under an accelerated deprecation timeline.

9.1.18 1.3 release

Django 1.3.7 release notes

February 20, 2013

Django 1.3.7 corrects a packaging problem with yesterday's [1.3.6 release](#).

The release contained stray `.pyc` files that caused “bad magic number” errors when running with some versions of Python. This release corrects this, and also fixes a bad documentation link in the project template `settings.py` file generated by `manage.py startproject`.

Django 1.3.6 release notes

February 19, 2013

Django 1.3.6 fixes four security issues present in previous Django releases in the 1.3 series.

This is the sixth bugfix/security release in the Django 1.3 series.

Host header poisoning

Some parts of Django –independent of end-user-written applications –make use of full URLs, including domain name, which are generated from the HTTP Host header. Django’s documentation has for some time contained notes advising users on how to configure web servers to ensure that only valid Host headers can reach the Django application. However, it has been reported to us that even with the recommended web server configurations there are still techniques available for tricking many common web servers into supplying the application with an incorrect and possibly malicious Host header.

For this reason, Django 1.3.6 adds a new setting, `ALLOWED_HOSTS`, which should contain an explicit list of valid host/domain names for this site. A request with a Host header not matching an entry in this list will raise `SuspiciousOperation` if `request.get_host()` is called. For full details see the documentation for the `ALLOWED_HOSTS` setting.

The default value for this setting in Django 1.3.6 is `['*']` (matching any host), for backwards-compatibility, but we strongly encourage all sites to set a more restrictive value.

This host validation is disabled when `DEBUG` is `True` or when running tests.

XML deserialization

The XML parser in the Python standard library is vulnerable to a number of attacks via external entities and entity expansion. Django uses this parser for deserializing XML-formatted database fixtures. The fixture deserializer is not intended for use with untrusted data, but in order to err on the side of safety in Django 1.3.6 the XML deserializer refuses to parse an XML document with a DTD (DOCTYPE definition), which closes off these attack avenues.

These issues in the Python standard library are CVE-2013-1664 and CVE-2013-1665. More information available [from the Python security team](#).

Django’s XML serializer does not create documents with a DTD, so this should not cause any issues with the typical round-trip from `dumpdata` to `loaddata`, but if you feed your own XML documents to the `loaddata` management command, you will need to ensure they do not contain a DTD.

Formset memory exhaustion

Previous versions of Django did not validate or limit the form-count data provided by the client in a formset’s management form, making it possible to exhaust a server’s available memory by forcing it to create very large numbers of forms.

In Django 1.3.6, all formsets have a strictly-enforced maximum number of forms (1000 by default, though it can be set higher via the `max_num` formset factory argument).

Admin history view information leakage

In previous versions of Django, an admin user without change permission on a model could still view the Unicode representation of instances via their admin history log. Django 1.3.6 now limits the admin history log view for an object to users with change permission for that model.

Django 1.3.5 release notes

December 10, 2012

Django 1.3.5 addresses two security issues present in previous Django releases in the 1.3 series.

Please be aware that this security release is slightly different from previous ones. Both issues addressed here have been dealt with in prior security updates to Django. In one case, we have received ongoing reports of problems, and in the other we've chosen to take further steps to tighten up Django's code in response to independent discovery of potential problems from multiple sources.

Host header poisoning

Several earlier Django security releases focused on the issue of poisoning the HTTP Host header, causing Django to generate URLs pointing to arbitrary, potentially-malicious domains.

In response to further input received and reports of continuing issues following the previous release, we're taking additional steps to tighten Host header validation. Rather than attempt to accommodate all features HTTP supports here, Django's Host header validation attempts to support a smaller, but far more common, subset:

- Hostnames must consist of characters [A-Za-z0-9] plus hyphen ('-') or dot ('.').
- IP addresses –both IPv4 and IPv6 –are permitted.
- Port, if specified, is numeric.

Any deviation from this will now be rejected, raising the exception `django.core.exceptions.SuspiciousOperation`.

Redirect poisoning

Also following up on a previous issue: in July of this year, we made changes to Django's HTTP redirect classes, performing additional validation of the scheme of the URL to redirect to (since, both within Django's own supplied applications and many third-party applications, accepting a user-supplied redirect target is a common pattern).

Since then, two independent audits of the code turned up further potential problems. So, similar to the Host-header issue, we are taking steps to provide tighter validation in response to reported problems (primarily with third-party applications, but to a certain extent also within Django itself). This comes in two parts:

1. A new utility function, `django.utils.http.is_safe_url`, is added; this function takes a URL and a hostname, and checks that the URL is either relative, or if absolute matches the supplied hostname. This function is intended for use whenever user-supplied redirect targets are accepted, to ensure that such redirects cannot lead to arbitrary third-party sites.
2. All of Django's own built-in views –primarily in the authentication system –which allow user-supplied redirect targets now use `is_safe_url` to validate the supplied URL.

Django 1.3.4 release notes

October 17, 2012

This is the fourth release in the Django 1.3 series.

Host header poisoning

Some parts of Django –independent of end-user-written applications –make use of full URLs, including domain name, which are generated from the HTTP Host header. Some attacks against this are beyond Django's ability to control, and require the web server to be properly configured; Django's documentation has for some time contained notes advising users on such configuration.

Django's own built-in parsing of the Host header is, however, still vulnerable, as was reported to us recently. The Host header parsing in Django 1.3.3 and Django 1.4.1 –specifically, `django.http.HttpRequest.get_host()` –was incorrectly handling username/password information in the header. Thus, for example, the following Host header would be accepted by Django when running on `validsite.com`:

```
Host: validsite.com:random@evilsite.com
```

Using this, an attacker can cause parts of Django –particularly the password-reset mechanism –to generate and display arbitrary URLs to users.

To remedy this, the parsing in `HttpRequest.get_host()` is being modified; Host headers which contain potentially dangerous content (such as username/password pairs) now raise the exception `django.core.exceptions.SuspiciousOperation`.

Details of this issue were initially posted online as a [security advisory](#).

Django 1.3.3 release notes

August 1, 2012

Following Monday's security release of [Django 1.3.2](#), we began receiving reports that one of the fixes applied was breaking Python 2.4 compatibility for Django 1.3. Since Python 2.4 is a supported Python version for that release series, this release fixes compatibility with Python 2.4.

Django 1.3.2 release notes

July 30, 2012

This is the second security release in the Django 1.3 series, fixing several security issues in Django 1.3. Django 1.3.2 is a recommended upgrade for all users of Django 1.3.

For a full list of issues addressed in this release, see the [security advisory](#).

Django 1.3.1 release notes

September 9, 2011

Welcome to Django 1.3.1!

This is the first security release in the Django 1.3 series, fixing several security issues in Django 1.3. Django 1.3.1 is a recommended upgrade for all users of Django 1.3.

For a full list of issues addressed in this release, see the [security advisory](#).

Django 1.3 release notes

March 23, 2011

Welcome to Django 1.3!

Nearly a year in the making, Django 1.3 includes quite a few [new features](#) and plenty of bug fixes and improvements to existing features. These release notes cover the new features in 1.3, as well as some [backwards-incompatible changes](#) you'll want to be aware of when upgrading from Django 1.2 or older versions.

Overview

Django 1.3's focus has mostly been on resolving smaller, long-standing feature requests, but that hasn't prevented a few fairly significant new features from landing, including:

- A framework for writing [class-based views](#).
- Built-in support for [using Python's logging facilities](#).
- Contrib support for [easy handling of static files](#).

- Django’s testing framework now supports (and ships with a copy of) [the unittest2 library](#).

Wherever possible, new features are introduced in a backwards-compatible manner per [our API stability policy](#). As a result of this policy, Django 1.3 [begins the deprecation process](#) for some features.

Python compatibility

The release of Django 1.2 was notable for having the first shift in Django’s Python compatibility policy; prior to Django 1.2, Django supported any 2.x version of Python from 2.3 up. As of Django 1.2, the minimum requirement was raised to Python 2.4.

Django 1.3 continues to support Python 2.4, but will be the final Django release series to do so; beginning with Django 1.4, the minimum supported Python version will be 2.5. A document outlining our full timeline for deprecating Python 2.x and moving to Python 3.x will be published shortly after the release of Django 1.3.

What’s new in Django 1.3

Class-based views

Django 1.3 adds a framework that allows you to use a class as a view. This means you can compose a view out of a collection of methods that can be subclassed and overridden to provide common views of data without having to write too much code.

Analogous to all the old function-based generic views have been provided, along with a completely generic view base class that can be used as the basis for reusable applications that can be easily extended.

See [the documentation on class-based generic views](#) for more details. There is also a document to help you [convert your function-based generic views to class-based views](#).

Logging

Django 1.3 adds framework-level support for Python’s `logging` module. This means you can now easily configure and control logging as part of your Django project. A number of logging handlers and logging calls have been added to Django’s own code as well –most notably, the error emails sent on an HTTP 500 server error are now handled as a logging activity. See [the documentation on Django’s logging interface](#) for more details.

Extended static files handling

Django 1.3 ships with a new contrib app `django.contrib.staticfiles` to help developers handle the static media files (images, CSS, JavaScript, etc.) that are needed to render a complete web page.

In previous versions of Django, it was common to place static assets in `MEDIA_ROOT` along with user-uploaded files, and serve them both at `MEDIA_URL`. Part of the purpose of introducing the `staticfiles` app is to make it easier to keep static files separate from user-uploaded files. Static assets should now go in `static/` subdirectories of your apps or in other static assets directories listed in `STATICFILES_DIRS`, and will be served at `STATIC_URL`.

See the [reference documentation of the app](#) for more details or learn how to [manage static files](#).

unittest2 support

Python 2.7 introduced some major changes to the `unittest` library, adding some extremely useful features. To ensure that every Django project can benefit from these new features, Django ships with a copy of `unittest2`, a copy of the Python 2.7 `unittest` library, backported for Python 2.4 compatibility.

To access this library, Django provides the `django.utils.unittest` module alias. If you are using Python 2.7, or you have installed `unittest2` locally, Django will map the alias to the installed version of the `unittest` library. Otherwise, Django will use its own bundled version of `unittest2`.

To take advantage of this alias, simply use:

```
from django.utils import unittest
```

wherever you would have historically used:

```
import unittest
```

If you want to continue to use the base `unittest` library, you can –you just won't get any of the nice new `unittest2` features.

Transaction context managers

Users of Python 2.5 and above may now use transaction management functions as context managers. For example:

```
with transaction.autocommit():  
    ...
```

Configurable delete-cascade

ForeignKey and *OneToOneField* now accept an *on_delete* argument to customize behavior when the referenced object is deleted. Previously, deletes were always cascaded; available alternatives now include set null, set default, set to any value, protect, or do nothing.

For more information, see the *on_delete* documentation.

Contextual markers and comments for translatable strings

For translation strings with ambiguous meaning, you can now use the `pgettext` function to specify the context of the string.

And if you just want to add some information for translators, you can also add special translator comments in the source.

For more information, see [Contextual markers and Comments for translators](#).

Improvements to built-in template tags

A number of improvements have been made to Django's built-in template tags:

- The *include* tag now accepts a `with` option, allowing you to specify context variables to the included template
- The *include* tag now accepts an `only` option, allowing you to exclude the current context from the included context
- The *with* tag now allows you to define multiple context variables in a single *with* block.
- The *load* tag now accepts a `from` argument, allowing you to load a single tag or filter from a library.

TemplateResponse

It can sometimes be beneficial to allow decorators or middleware to modify a response after it has been constructed by the view. For example, you may want to change the template that is used, or put additional data into the context.

However, you can't (easily) modify the content of a basic *HttpResponse* after it has been constructed. To overcome this limitation, Django 1.3 adds a new *TemplateResponse* class. Unlike basic *HttpResponse* objects, *TemplateResponse* objects retain the details of the template and context that was provided by the view to compute the response. The final output of the response is not computed until it is needed, later in the response process.

For more details, see the [documentation](#) on the *TemplateResponse* class.

Caching changes

Django 1.3 sees the introduction of several improvements to the Django' s caching infrastructure.

Firstly, Django now supports multiple named caches. In the same way that Django 1.2 introduced support for multiple database connections, Django 1.3 allows you to use the new `CACHES` setting to define multiple named cache connections.

Secondly, `versioning`, `site-wide prefixing` and `transformation` have been added to the cache API.

Thirdly, `cache key creation` has been updated to take the request query string into account on GET requests.

Finally, support for `pylibmc` has been added to the memcached cache backend.

For more details, see the [documentation on caching in Django](#).

Permissions for inactive users

If you provide a custom auth backend with `supports_inactive_user` set to `True`, an inactive `User` instance will check the backend for permissions. This is useful for further centralizing the permission handling. See the [authentication docs](#) for more details.

GeoDjango

The GeoDjango test suite is now included when running the Django test suite with `runtests.py` when using [spatial database backends](#).

`MEDIA_URL` and `STATIC_URL` must end in a slash

Previously, the `MEDIA_URL` setting only required a trailing slash if it contained a suffix beyond the domain name.

A trailing slash is now required for `MEDIA_URL` and the new `STATIC_URL` setting as long as it is not blank. This ensures there is a consistent way to combine paths in templates.

Project settings which provide either of both settings without a trailing slash will now raise a `PendingDeprecationWarning`.

In Django 1.4 this same condition will raise `DeprecationWarning`, and in Django 1.5 will raise an `ImproperlyConfigured` exception.

Everything else

Django 1.1 and 1.2 added lots of big ticket items to Django, like multiple-database support, model validation, and a session-based messages framework. However, this focus on big features came at the cost of lots of smaller features.

To compensate for this, the focus of the Django 1.3 development process has been on adding lots of smaller, long standing feature requests. These include:

- Improved tools for accessing and manipulating the current *Site* object in [the sites framework](#).
- A *RequestFactory* for mocking requests in tests.
- A new test assertion `assertNumQueries()` –making it easier to test the database activity associated with a view.
- Support for lookups spanning relations in admin’ s *list_filter*.
- Support for *HttpOnly* cookies.
- *mail_admins()* and *mail_managers()* now support easily attaching HTML content to messages.
- *EmailMessage* now supports CC’ s.
- Error emails now include more of the detail and formatting of the debug server error page.
- *simple_tag()* now accepts a *takes_context* argument, making it easier to write simple template tags that require access to template context.
- A new *render()* shortcut –an alternative to `django.shortcuts.render_to_response()` providing a *RequestContext* by default.
- Support for combining *F expressions* with *timedelta* values when retrieving or updating database values.

Backwards-incompatible changes in 1.3

CSRF validation now applies to AJAX requests

Prior to Django 1.2.5, Django’ s CSRF-prevention system exempted AJAX requests from CSRF verification; due to [security issues](#) reported to us, however, all requests are now subjected to CSRF verification. Consult [the Django CSRF documentation](#) for details on how to handle CSRF verification in AJAX requests.

Restricted filters in admin interface

Prior to Django 1.2.5, the Django administrative interface allowed filtering on any model field or relation – not just those specified in `list_filter` – via query string manipulation. Due to security issues reported to us, however, query string lookup arguments in the admin must be for fields or relations specified in `list_filter` or `date_hierarchy`.

Deleting a model doesn't delete associated files

In earlier Django versions, when a model instance containing a *FileField* was deleted, *FileField* took it upon itself to also delete the file from the backend storage. This opened the door to several data-loss scenarios, including rolled-back transactions and fields on different models referencing the same file. In Django 1.3, when a model is deleted the *FileField*'s `delete()` method won't be called. If you need cleanup of orphaned files, you'll need to handle it yourself (for instance, with a custom management command that can be run manually or scheduled to run periodically via e.g. cron).

PasswordInput default rendering behavior

The *PasswordInput* form widget, intended for use with form fields which represent passwords, accepts a boolean keyword argument `render_value` indicating whether to send its data back to the browser when displaying a submitted form with errors. Prior to Django 1.3, this argument defaulted to `True`, meaning that the submitted password would be sent back to the browser as part of the form. Developers who wished to add a bit of additional security by excluding that value from the redisplayed form could instantiate a *PasswordInput* passing `render_value=False`.

Due to the sensitive nature of passwords, however, Django 1.3 takes this step automatically; the default value of `render_value` is now `False`, and developers who want the password value returned to the browser on a submission with errors (the previous behavior) must now explicitly indicate this. For example:

```
class LoginForm(forms.Form):
    username = forms.CharField(max_length=100)
    password = forms.CharField(widget=forms.PasswordInput(render_value=True))
```

Clearable default widget for FileField

Django 1.3 now includes a *ClearableFileInput* form widget in addition to *FileInput*. *ClearableFileInput* renders with a checkbox to clear the field's value (if the field has a value and is not required); *FileInput* provided no means for clearing an existing file from a *FileField*.

ClearableFileInput is now the default widget for a *FileField*, so existing forms including *FileField* without assigning a custom widget will need to account for the possible extra checkbox in the rendered form output.

To return to the previous rendering (without the ability to clear the `FileField`), use the `FileInput` widget in place of `ClearableFileInput`. For instance, in a `ModelForm` for a hypothetical `Document` model with a `FileField` named `document`:

```
from django import forms
from myapp.models import Document

class DocumentForm(forms.ModelForm):
    class Meta:
        model = Document
        widgets = {"document": forms.FileInput}
```

New index on database session table

Prior to Django 1.3, the database table used by the database backend for the `sessions` app had no index on the `expire_date` column. As a result, date-based queries on the session table –such as the query that is needed to purge old sessions –would be very slow if there were lots of sessions.

If you have an existing project that is using the database session backend, you don't have to do anything to accommodate this change. However, you may get a significant performance boost if you manually add the new index to the session table. The SQL that will add the index can be found by running the `sqlindexes` admin command:

```
python manage.py sqlindexes sessions
```

No more naughty words

Django has historically provided (and enforced) a list of profanities. The comments app has enforced this list of profanities, preventing people from submitting comments that contained one of those profanities.

Unfortunately, the technique used to implement this profanities list was woefully naive, and prone to the [Scunthorpe problem](#). Improving the built-in filter to fix this problem would require significant effort, and since natural language processing isn't the normal domain of a web framework, we have “fixed” the problem by making the list of prohibited words an empty list.

If you want to restore the old behavior, simply put a `PROFANITIES_LIST` setting in your settings file that includes the words that you want to prohibit (see the [commit that implemented this change](#) if you want to see the list of words that was historically prohibited). However, if avoiding profanities is important to you, you would be well advised to seek out a better, less naive approach to the problem.

Localflavor changes

Django 1.3 introduces the following backwards-incompatible changes to local flavors:

- Canada (ca) –The province “Newfoundland and Labrador” has had its province code updated to “NL” , rather than the older “NF” . In addition, the Yukon Territory has had its province code corrected to “YT” , instead of “YK” .
- Indonesia (id) –The province “Nanggroe Aceh Darussalam (NAD)” has been removed from the province list in favor of the new official designation “Aceh (ACE)” .
- United States of America (us) –The list of “states” used by `USStateField` has expanded to include Armed Forces postal codes. This is backwards-incompatible if you were relying on `USStateField` not including them.

FormSet updates

In Django 1.3 `FormSet` creation behavior is modified slightly. Historically the class didn’ t make a distinction between not being passed data and being passed empty dictionary. This was inconsistent with behavior in other parts of the framework. Starting with 1.3 if you pass in empty dictionary the `FormSet` will raise a `ValidationError`.

For example with a `FormSet`:

```
>>> class ArticleForm(Form):
...     title = CharField()
...     pub_date = DateField()
...
>>> ArticleFormSet = formset_factory(ArticleForm)
```

the following code will raise a `ValidationError`:

```
>>> ArticleFormSet({})
Traceback (most recent call last):
...
ValidationError: [u'ManagementForm data is missing or has been tampered with']
```

if you need to instantiate an empty `FormSet`, don’ t pass in the data or use `None`:

```
>>> formset = ArticleFormSet()
>>> formset = ArticleFormSet(data=None)
```

Callables in templates

Previously, a callable in a template would only be called automatically as part of the variable resolution process if it was retrieved via attribute lookup. This was an inconsistency that could result in confusing and unhelpful behavior:

```
>>> Template("{ user.get_full_name }").render(Context({"user": user}))
u'Joe Bloggs'
>>> Template("{ full_name }").render(Context({"full_name": user.get_full_name}))
u'&lt;bound method User.get_full_name of &lt;...>'
```

This has been resolved in Django 1.3 - the result in both cases will be `u'Joe Bloggs'`. Although the previous behavior was not useful for a template language designed for web designers, and was never deliberately supported, it is possible that some templates may be broken by this change.

Use of custom SQL to load initial data in tests

Django provides a custom SQL hooks as a way to inject hand-crafted SQL into the database synchronization process. One of the possible uses for this custom SQL is to insert data into your database. If your custom SQL contains `INSERT` statements, those insertions will be performed every time your database is synchronized. This includes the synchronization of any test databases that are created when you run a test suite.

However, in the process of testing the Django 1.3, it was discovered that this feature has never completely worked as advertised. When using database backends that don't support transactions, or when using a `TransactionTestCase`, data that has been inserted using custom SQL will not be visible during the testing process.

Unfortunately, there was no way to rectify this problem without introducing a backwards incompatibility. Rather than leave SQL-inserted initial data in an uncertain state, Django now enforces the policy that data inserted by custom SQL will not be visible during testing.

This change only affects the testing process. You can still use custom SQL to load data into your production database as part of the `syncdb` process. If you require data to exist during test conditions, you should either insert it using `test fixtures`, or using the `setUp()` method of your test case.

Changed priority of translation loading

Work has been done to simplify, rationalize and properly document the algorithm used by Django at runtime to build translations from the different translations found on disk, namely:

For translatable literals found in Python code and templates (`'django'` gettext domain):

- Priorities of translations included with applications listed in the `INSTALLED_APPS` setting were changed. To provide a behavior consistent with other parts of Django that also use such setting (templates, etc.)

now, when building the translation that will be made available, the apps listed first have higher precedence than the ones listed later.

- Now it is possible to override the translations shipped with applications by using the `LOCALE_PATHS` setting whose translations have now higher precedence than the translations of `INSTALLED_APPS` applications. The relative priority among the values listed in this setting has also been modified so the paths listed first have higher precedence than the ones listed later.
- The `locale` subdirectory of the directory containing the settings, that usually coincides with and is known as the project directory is being deprecated in this release as a source of translations. (the precedence of these translations is intermediate between applications and `LOCALE_PATHS` translations). See the [corresponding deprecated features section](#) of this document.

For translatable literals found in JavaScript code ('`djangojs`' gettext domain):

- Similarly to the '`django`' domain translations: Overriding of translations shipped with applications by using the `LOCALE_PATHS` setting is now possible for this domain too. These translations have higher precedence than the translations of Python packages passed to the `javascript_catalog()` view. Paths listed first have higher precedence than the ones listed later.
- Translations under the `locale` subdirectory of the project directory have never been taken in account for JavaScript translations and remain in the same situation considering the deprecation of such location.

Transaction management

When using managed transactions—that is, anything but the default autocommit mode—it is important when a transaction is marked as “dirty”. Dirty transactions are committed by the `commit_on_success` decorator or the `django.middleware.transaction.TransactionMiddleware`, and `commit_manually` forces them to be closed explicitly; clean transactions “get a pass”, which means they are usually rolled back at the end of a request when the connection is closed.

Until Django 1.3, transactions were only marked dirty when Django was aware of a modifying operation performed in them; that is, either some model was saved, some bulk update or delete was performed, or the user explicitly called `transaction.set_dirty()`. In Django 1.3, a transaction is marked dirty when any database operation is performed.

As a result of this change, you no longer need to set a transaction dirty explicitly when you execute raw SQL or use a data-modifying `SELECT`. However, you do need to explicitly close any read-only transactions that are being managed using `commit_manually()`. For example:

```
@transaction.commit_manually
def my_view(request, name):
    obj = get_object_or_404(MyObject, name__iexact=name)
    return render_to_response("template", {"object": obj})
```

Prior to Django 1.3, this would work without error. However, under Django 1.3, this will raise a *TransactionManagementError* because the read operation that retrieves the `MyObject` instance leaves the transaction in a dirty state.

No password reset for inactive users

Prior to Django 1.3, inactive users were able to request a password reset email and reset their password. In Django 1.3 inactive users will receive the same message as a nonexistent account.

Password reset view now accepts `from_email`

The `django.contrib.auth.views.password_reset()` view now accepts a `from_email` parameter, which is passed to the `password_reset_form`'s `save()` method as a keyword argument. If you are using this view with a custom password reset form, then you will need to ensure your form's `save()` method accepts this keyword argument.

Features deprecated in 1.3

Django 1.3 deprecates some features from earlier releases. These features are still supported, but will be gradually phased out over the next few release cycles.

Code taking advantage of any of the features below will raise a `PendingDeprecationWarning` in Django 1.3. This warning will be silent by default, but may be turned on using Python's `warnings` module, or by running Python with a `-Wd` or `-Wall` flag.

In Django 1.4, these warnings will become a `DeprecationWarning`, which is not silent. In Django 1.5 support for these features will be removed entirely.

See also:

For more details, see the documentation [Django's release process](#) and our [deprecation timeline](#).

`mod_python` support

The `mod_python` library has not had a release since 2007 or a commit since 2008. The Apache Foundation board voted to remove `mod_python` from the set of active projects in its version control repositories, and its lead developer has shifted all of his efforts toward the lighter, slimmer, more stable, and more flexible `mod_wsgi` backend.

If you are currently using the `mod_python` request handler, you should redeploy your Django projects using another request handler. `mod_wsgi` is the request handler recommended by the Django project, but FastCGI is also supported. Support for `mod_python` deployment will be removed in Django 1.5.

Function-based generic views

As a result of the introduction of class-based generic views, the function-based generic views provided by Django have been deprecated. The following modules and the views they contain have been deprecated:

- `django.views.generic.create_update`
- `django.views.generic.date_based`
- `django.views.generic.list_detail`
- `django.views.generic.simple`

Test client response template attribute

Django's `test client` returns *Response* objects annotated with extra testing information. In Django versions prior to 1.3, this included a `template` attribute containing information about templates rendered in generating the response: either `None`, a single *Template* object, or a list of *Template* objects. This inconsistency in return values (sometimes a list, sometimes not) made the attribute difficult to work with.

In Django 1.3 the `template` attribute is deprecated in favor of a new *templates* attribute, which is always a list, even if it has only a single element or no elements.

DjangoTestRunner

As a result of the introduction of support for `unittest2`, the features of `django.test.simple.DjangoTestRunner` (including fail-fast and Ctrl-C test termination) have been made redundant. In view of this redundancy, `DjangoTestRunner` has been turned into an empty placeholder class, and will be removed entirely in Django 1.5.

Changes to url and ssi

Most template tags will allow you to pass in either constants or variables as arguments –for example:

```
{% extends "base.html" %}
```

allows you to specify a base template as a constant, but if you have a context variable `templ` that contains the value `base.html`:

```
{% extends templ %}
```

is also legal.

However, due to an accident of history, the `url` and `ssi` are different. These tags use the second, quoteless syntax, but interpret the argument as a constant. This means it isn't possible to use a context variable as the target of a `url` and `ssi` tag.

Django 1.3 marks the start of the process to correct this historical accident. Django 1.3 adds a new template library `future` that provides alternate implementations of the `url` and `ssi` template tags. This `future` library implement behavior that makes the handling of the first argument consistent with the handling of all other variables. So, an existing template that contains:

```
{% url sample %}
```

should be replaced with:

```
{% load url from future %}
{% url 'sample' %}
```

The tags implementing the old behavior have been deprecated, and in Django 1.5, the old behavior will be replaced with the new behavior. To ensure compatibility with future versions of Django, existing templates should be modified to use the new `future` libraries and syntax.

Changes to the login methods of the admin

In previous version the admin app defined login methods in multiple locations and ignored the almost identical implementation in the already used auth app. A side effect of this duplication was the missing adoption of the changes made in [r12634](#) to support a broader set of characters for usernames.

This release refactors the admin's login mechanism to use a subclass of the `AuthenticationForm` instead of a manual form validation. The previously undocumented method `'django.contrib.admin.sites.AdminSite.display_login_form'` has been removed in favor of a new `login_form` attribute.

reset and sqlreset management commands

Those commands have been deprecated. The `flush` and `sqlflush` commands can be used to delete everything. You can also use `ALTER TABLE` or `DROP TABLE` statements manually.

GeoDjango

- The function-based `TEST_RUNNER` previously used to execute the GeoDjango test suite, `django.contrib.gis.tests.run_gis_tests`, was deprecated for the class-based runner, `django.contrib.gis.tests.GeoDjangoTestSuiteRunner`.
- Previously, calling `transform()` would silently do nothing when GDAL wasn't available. Now, a `GEOSException` is properly raised to indicate possible faulty application code. A warning is now raised if `transform()` is called when the SRID of the geometry is less than 0 or None.

CZBirthNumberField.clean

Previously this field's `clean()` method accepted a second, `gender`, argument which allowed stronger validation checks to be made, however since this argument could never actually be passed from the Django form machinery it is now pending deprecation.

CompatCookie

Previously, `django.http` exposed an undocumented `CompatCookie` class, which was a bugfix wrapper around the standard library `SimpleCookie`. As the fixes are moving upstream, this is now deprecated - you should use `from django.http import SimpleCookie` instead.

Loading of *project-level* translations

This release of Django starts the deprecation process for inclusion of translations located under the so-called project path in the translation building process performed at runtime. The `LOCALE_PATHS` setting can be used for the same task by adding the filesystem path to a `locale` directory containing project-level translations to the value of that setting.

Rationale for this decision:

- The project path has always been a loosely defined concept (actually, the directory used for locating project-level translations is the directory containing the settings module) and there has been a shift in other parts of the framework to stop using it as a reference for location of assets at runtime.
- Detection of the `locale` subdirectory tends to fail when the deployment scenario is more complex than the basic one. e.g. it fails when the settings module is a directory (ticket #10765).
- There are potential strange development- and deployment-time problems like the fact that the `project_dir/locale/` subdir can generate spurious error messages when the project directory is added to the Python path (`manage.py runserver` does this) and then it clashes with the equally named standard library module, this is a typical warning message:

```
/usr/lib/python2.6/gettext.py:49: ImportWarning: Not importing directory '/path/to/project/
↳ locale': missing __init__.py.
import locale, copy, os, re, struct, sys
```

- This location wasn't included in the translation building process for JavaScript literals. This deprecation removes such inconsistency.

PermWrapper moved to `django.contrib.auth.context_processors`

In Django 1.2, we began the process of changing the location of the `auth` context processor from `django.core.context_processors` to `django.contrib.auth.context_processors`. However, the `PermWrapper` support class was mistakenly omitted from that migration. In Django 1.3, the `PermWrapper` class has also been moved to `django.contrib.auth.context_processors`, along with the `PermLookupDict` support class. The new classes are functionally identical to their old versions; only the module location has changed.

Removal of `XMLField`

When Django was first released, Django included an `XMLField` that performed automatic XML validation for any field input. However, this validation function hasn't been performed since the introduction of `newforms`, prior to the 1.0 release. As a result, `XMLField` as currently implemented is functionally indistinguishable from a simple `TextField`.

For this reason, Django 1.3 has fast-tracked the deprecation of `XMLField`—instead of a two-release deprecation, `XMLField` will be removed entirely in Django 1.4.

It's easy to update your code to accommodate this change—just replace all uses of `XMLField` with `TextField`, and remove the `schema_path` keyword argument (if it is specified).

9.1.19 1.2 release

Django 1.2.7 release notes

September 10, 2011

Welcome to Django 1.2.7!

This is the seventh bugfix/security release in the Django 1.2 series. It replaces Django 1.2.6 due to problems with the 1.2.6 release tarball. Django 1.2.7 is a recommended upgrade for all users of any Django release in the 1.2.X series.

For more information, see the [release advisory](#).

Django 1.2.6 release notes

September 9, 2011

Welcome to Django 1.2.6!

This is the sixth bugfix/security release in the Django 1.2 series, fixing several security issues present in Django 1.2.5. Django 1.2.6 is a recommended upgrade for all users of any Django release in the 1.2.X series.

For a full list of issues addressed in this release, see the [security advisory](#).

Django 1.2.5 release notes

Welcome to Django 1.2.5!

This is the fifth “bugfix” release in the Django 1.2 series, improving the stability and performance of the Django 1.2 codebase.

With four exceptions, Django 1.2.5 maintains backwards compatibility with Django 1.2.4. It also contains a number of fixes and other improvements. Django 1.2.5 is a recommended upgrade for any development or deployment currently using or targeting Django 1.2.

For full details on the new features, backwards incompatibilities, and deprecated features in the 1.2 branch, see the [Django 1.2 release notes](#).

Backwards incompatible changes

CSRF exception for AJAX requests

Django includes a CSRF-protection mechanism, which makes use of a token inserted into outgoing forms. Middleware then checks for the token’s presence on form submission, and validates it.

Prior to Django 1.2.5, our CSRF protection made an exception for AJAX requests, on the following basis:

- Many AJAX toolkits add an X-Requested-With header when using XMLHttpRequest.
- Browsers have strict same-origin policies regarding XMLHttpRequest.
- In the context of a browser, the only way that a custom header of this nature can be added is with XMLHttpRequest.

Therefore, for ease of use, we did not apply CSRF checks to requests that appeared to be AJAX on the basis of the X-Requested-With header. The Ruby on Rails web framework had a similar exemption.

Recently, engineers at Google made members of the Ruby on Rails development team aware of a combination of browser plugins and redirects which can allow an attacker to provide custom HTTP headers on a request to any website. This can allow a forged request to appear to be an AJAX request, thereby defeating CSRF protection which trusts the same-origin nature of AJAX requests.

Michael Koziarski of the Rails team brought this to our attention, and we were able to produce a proof-of-concept demonstrating the same vulnerability in Django’s CSRF handling.

To remedy this, Django will now apply full CSRF validation to all requests, regardless of apparent AJAX origin. This is technically backwards-incompatible, but the security risks have been judged to outweigh the compatibility concerns in this case.

Additionally, Django will now accept the CSRF token in the custom HTTP header X-CSRFToken, as well as in the form submission itself, for ease of use with popular JavaScript toolkits which allow insertion of custom headers into all AJAX requests.

Please see the [CSRF docs](#) for example jQuery code that demonstrates this technique, ensuring that you are looking at the documentation for your version of Django, as the exact code necessary is different for some older versions of Django.

FileField no longer deletes files

In earlier Django versions, when a model instance containing a *FileField* was deleted, *FileField* took it upon itself to also delete the file from the backend storage. This opened the door to several potentially serious data-loss scenarios, including rolled-back transactions and fields on different models referencing the same file. In Django 1.2.5, *FileField* will never delete files from the backend storage. If you need cleanup of orphaned files, you'll need to handle it yourself (for instance, with a custom management command that can be run manually or scheduled to run periodically via e.g. cron).

Use of custom SQL to load initial data in tests

Django provides a custom SQL hooks as a way to inject hand-crafted SQL into the database synchronization process. One of the possible uses for this custom SQL is to insert data into your database. If your custom SQL contains `INSERT` statements, those insertions will be performed every time your database is synchronized. This includes the synchronization of any test databases that are created when you run a test suite.

However, in the process of testing the Django 1.3, it was discovered that this feature has never completely worked as advertised. When using database backends that don't support transactions, or when using a `TransactionTestCase`, data that has been inserted using custom SQL will not be visible during the testing process.

Unfortunately, there was no way to rectify this problem without introducing a backwards incompatibility. Rather than leave SQL-inserted initial data in an uncertain state, Django now enforces the policy that data inserted by custom SQL will not be visible during testing.

This change only affects the testing process. You can still use custom SQL to load data into your production database as part of the `syncdb` process. If you require data to exist during test conditions, you should either insert it using `test fixtures`, or using the `setUp()` method of your test case.

ModelAdmin.lookup_allowed signature changed

Django 1.2.4 introduced a method `lookup_allowed` on `ModelAdmin`, to cope with a security issue (changeset [15033]). Although this method was never documented, it seems some people have overridden `lookup_allowed`, especially to cope with regressions introduced by that changeset. While the method is still undocumented and not marked as stable, it may be helpful to know that the signature of this function has changed.

Django 1.2.4 release notes

Welcome to Django 1.2.4!

This is the fourth “bugfix” release in the Django 1.2 series, improving the stability and performance of the Django 1.2 codebase.

With one exception, Django 1.2.4 maintains backwards compatibility with Django 1.2.3. It also contains a number of fixes and other improvements. Django 1.2.4 is a recommended upgrade for any development or deployment currently using or targeting Django 1.2.

For full details on the new features, backwards incompatibilities, and deprecated features in the 1.2 branch, see the [Django 1.2 release notes](#).

Backwards incompatible changes

Restricted filters in admin interface

The Django administrative interface, `django.contrib.admin`, supports filtering of displayed lists of objects by fields on the corresponding models, including across database-level relationships. This is implemented by passing lookup arguments in the `querystring` portion of the URL, and options on the `ModelAdmin` class allow developers to specify particular fields or relationships which will generate automatic links for filtering.

One historically-undocumented and -unofficially-supported feature has been the ability for a user with sufficient knowledge of a model’s structure and the format of these lookup arguments to invent useful new filters on the fly by manipulating the `querystring`.

However, it has been demonstrated that this can be abused to gain access to information outside of an admin user’s permissions; for example, an attacker with access to the admin and sufficient knowledge of model structure and relations could construct query strings which –with repeated use of regular-expression lookups supported by the Django database API –expose sensitive information such as users’ password hashes.

To remedy this, `django.contrib.admin` will now validate that `querystring` lookup arguments either specify only fields on the model being viewed, or cross relations which have been explicitly allowed by the application developer using the preexisting mechanism mentioned above. This is backwards-incompatible for any users relying on the prior ability to insert arbitrary lookups.

One new feature

Ordinarily, a point release would not include new features, but in the case of Django 1.2.4, we have made an exception to this rule.

One of the bugs fixed in Django 1.2.4 involves a set of circumstances whereby a running a test suite on a multiple database configuration could cause the original source database (i.e., the actual production database) to be dropped, causing catastrophic loss of data. In order to provide a fix for this problem, it was necessary

to introduce a new setting –`TEST_DEPENDENCIES`–that allows you to define any creation order dependencies in your database configuration.

Most users –even users with multiple-database configurations–need not be concerned about the data loss bug, or the manual configuration of `TEST_DEPENDENCIES`. See the [original problem report](#) documentation on [controlling the creation order of test databases](#) for details.

GeoDjango

The function-based `TEST_RUNNER` previously used to execute the GeoDjango test suite, `django.contrib.gis.tests.run_gis_tests`, was finally deprecated in favor of a class-based test runner, `django.contrib.gis.tests.GeoDjangoTestSuiteRunner`, added in this release.

In addition, the GeoDjango test suite is now included when [running the Django test suite](#) with `runtests.py` and using [spatial database backends](#).

Django 1.2.3 release notes

Django 1.2.3 fixed a couple of release problems in the 1.2.2 release and was released two days after 1.2.2.

This release corrects the following problems:

- The [patch](#) applied for the security issue covered in Django 1.2.2 caused issues with non-ASCII responses using CSRF tokens.
- The patch also caused issues with some forms, most notably the user-editing forms in the Django administrative interface.
- The packaging manifest did not contain the full list of required files.

Django 1.2.2 release notes

Welcome to Django 1.2.2!

This is the second “bugfix” release in the Django 1.2 series, improving the stability and performance of the Django 1.2 codebase.

Django 1.2.2 maintains backwards compatibility with Django 1.2.1, but contain a number of fixes and other improvements. Django 1.2.2 is a recommended upgrade for any development or deployment currently using or targeting Django 1.2.

For full details on the new features, backwards incompatibilities, and deprecated features in the 1.2 branch, see the [Django 1.2 release notes](#).

One new feature

Ordinarily, a point release would not include new features, but in the case of Django 1.2.2, we have made an exception to this rule.

In order to test a bug fix that forms part of the 1.2.2 release, it was necessary to add a feature –the `enforce_csrf_checks` flag –to the `test client`. This flag forces the test client to perform full CSRF checks on forms. The default behavior of the test client hasn't changed, but if you want to do CSRF checks with the test client, it is now possible to do so.

Django 1.2.1 release notes

Django 1.2.1 was released almost immediately after 1.2.0 to correct two small bugs: one was in the documentation packaging script, the other was a [bug](#) that affected datetime form field widgets when localization was enabled.

Django 1.2 release notes

May 17, 2010.

Welcome to Django 1.2!

Nearly a year in the making, Django 1.2 packs an impressive list of [new features](#) and lots of bug fixes. These release notes cover the new features, as well as important changes you'll want to be aware of when upgrading from Django 1.1 or older versions.

Overview

Django 1.2 introduces several large, important new features, including:

- Support for [multiple database connections](#) in a single Django instance.
- [Model validation](#) inspired by Django's form validation.
- Vastly [improved protection against Cross-Site Request Forgery \(CSRF\)](#).
- A new user “messages” framework with support for cookie- and session-based message for both anonymous and authenticated users.
- Hooks for object-level permissions, permissions for anonymous users, and [more flexible username requirements](#).
- Customization of email sending via [email backends](#).
- New “smart” [if template tag](#) which supports comparison operators.

These are just the highlights; full details and a complete list of features [may be found below](#).

See also:

[Django Advent](#) covered the release of Django 1.2 with a series of articles and tutorials that cover some of the new features in depth.

Wherever possible these features have been introduced in a backwards-compatible manner per [our API stability policy](#).

However, a handful of features have changed in ways that, for some users, will be backwards-incompatible. The big changes are:

- Support for Python 2.3 has been dropped. See the full notes below.
- The new CSRF protection framework is not backwards-compatible with the old system. Users of the old system will not be affected until the old system is removed in Django 1.4.

However, upgrading to the new CSRF protection framework requires a few important backwards-incompatible changes, detailed in [CSRF Protection](#), below.

- Authors of custom *Field* subclasses should be aware that a number of methods have had a change in prototype, detailed under [get_db_prep_*\(\) methods on Field](#), below.
- The internals of template tags have changed somewhat; authors of custom template tags that need to store state (e.g. custom control flow tags) should ensure that their code follows the new rules for [stateful template tags](#)
- The `user_passes_test()`, `login_required()`, and `permission_required()`, decorators from `django.contrib.auth` only apply to functions and no longer work on methods. There's a simple one-line fix [detailed below](#).

Again, these are just the big features that will affect the most users. Users upgrading from previous versions of Django are heavily encouraged to consult the complete list of [backwards-incompatible changes](#) and the list of [deprecated features](#).

Python compatibility

While not a new feature, it's important to note that Django 1.2 introduces the first shift in our Python compatibility policy since Django's initial public debut. Previous Django releases were tested and supported on 2.x Python versions from 2.3 up; Django 1.2, however, drops official support for Python 2.3. As such, the minimum Python version required for Django is now 2.4, and Django is tested and supported on Python 2.4, 2.5 and 2.6, and will be supported on the as-yet-unreleased Python 2.7.

This change should affect only a small number of Django users, as most operating-system vendors today are shipping Python 2.4 or newer as their default version. If you're still using Python 2.3, however, you'll need to stick to Django 1.1 until you can upgrade; per [our support policy](#), Django 1.1 will continue to receive security support until the release of Django 1.3.

A roadmap for Django’s overall 2.x Python support, and eventual transition to Python 3.x, is currently being developed, and will be announced prior to the release of Django 1.3.

What’s new in Django 1.2

Support for multiple databases

Django 1.2 adds the ability to use [more than one database](#) in your Django project. Queries can be issued at a specific database with the `using()` method on `QuerySet` objects. Individual objects can be saved to a specific database by providing a `using` argument when you call `save()`.

Model validation

Model instances now have support for [validating their own data](#), and both model and form fields now accept configurable lists of [validators](#) specifying reusable, encapsulated validation behavior. Note, however, that validation must still be performed explicitly. Simply invoking a model instance’s `save()` method will not perform any validation of the instance’s data.

Improved CSRF protection

Django now has much improved protection against [Cross-Site Request Forgery \(CSRF\) attacks](#). This type of attack occurs when a malicious website contains a link, a form button or some JavaScript that is intended to perform some action on your website, using the credentials of a logged-in user who visits the malicious site in their browser. A related type of attack, “login CSRF,” where an attacking site tricks a user’s browser into logging into a site with someone else’s credentials, is also covered.

Messages framework

Django now includes a robust and configurable [messages framework](#) with built-in support for cookie- and session-based messaging, for both anonymous and authenticated clients. The messages framework replaces the deprecated user message API and allows you to temporarily store messages in one request and retrieve them for display in a subsequent request (usually the next one).

Object-level permissions

A foundation for specifying permissions at the per-object level has been added. Although there is no implementation of this in core, a custom authentication backend can provide this implementation and it will be used by `django.contrib.auth.models.User`. See the [authentication docs](#) for more information.

Permissions for anonymous users

If you provide a custom auth backend with `supports_anonymous_user` set to `True`, `AnonymousUser` will check the backend for permissions, just like `User` already did. This is useful for centralizing permission handling - apps can always delegate the question of whether something is allowed or not to the authorization/authentication backend. See the [authentication docs](#) for more details.

Relaxed requirements for usernames

The built-in `User` model's `username` field now allows a wider range of characters, including `@`, `+`, `.` and `-` characters.

Email backends

You can now [configure the way that Django sends email](#). Instead of using SMTP to send all email, you can now choose a configurable email backend to send messages. If your hosting provider uses a sandbox or some other non-SMTP technique for sending mail, you can now construct an email backend that will allow Django's standard [mail sending methods](#) to use those facilities.

This also makes it easier to debug mail sending. Django ships with backend implementations that allow you to send email to a [file](#), to the [console](#), or to [memory](#). You can even configure all email to be [thrown away](#).

“Smart” if tag

The `if` tag has been upgraded to be much more powerful. First, we've added support for comparison operators. No longer will you have to type:

```
{% ifnotequal a b %}
...
{% endifnotequal %}
```

You can now do this:

```
{% if a != b %}
...
{% endif %}
```

There's really no reason to use `{% ifequal %}` or `{% ifnotequal %}` anymore, unless you're the nostalgic type.

The operators supported are `==`, `!=`, `<`, `>`, `<=`, `>=`, `in` and `not in`, all of which work like the Python operators, in addition to `and`, `or` and `not`, which were already supported.

Also, filters may now be used in the `if` expression. For example:

```
<div
  {% if user.email|lower == message.recipient|lower %}
    class="highlight"
  {% endif %}
>{{ message }}</div>
```

Template caching

In previous versions of Django, every time you rendered a template, it would be reloaded from disk. In Django 1.2, you can use a [cached template loader](#) to load templates once, then cache the result for every subsequent render. This can lead to a significant performance improvement if your templates are broken into lots of smaller subtemplates (using the `{% extends %}` or `{% include %}` tags).

As a side effect, it is now much easier to support non-Django template languages.

Class-based template loaders

As part of the changes made to introduce [Template caching](#) and following a general trend in Django, the template loaders API has been modified to use template loading mechanisms that are encapsulated in Python classes as opposed to functions, the only method available until Django 1.1.

All the template loaders [shipped with Django](#) have been ported to the new API but they still implement the function-based API and the template core machinery still accepts function-based loaders (builtin or third party) so there is no immediate need to modify your `TEMPLATE_LOADERS` setting in existing projects, things will keep working if you leave it untouched up to and including the Django 1.3 release.

If you have developed your own custom template loaders we suggest to consider porting them to a class-based implementation because the code for backwards compatibility with function-based loaders starts its deprecation process in Django 1.2 and will be removed in Django 1.4. There is a description of the API these loader classes must implement in the [template API reference](#) and you can also examine the source code of the loaders shipped with Django.

Natural keys in fixtures

Fixtures can now refer to remote objects using [Natural keys](#). This lookup scheme is an alternative to the normal primary-key based object references in a fixture, improving readability and resolving problems referring to objects whose primary key value may not be predictable or known.

Fast failure for tests

Both the `test` subcommand of `django-admin.py` and the `runtests.py` script used to run Django's own test suite now support a `--failfast` option. When specified, this option causes the test runner to exit after encountering a failure instead of continuing with the test run. In addition, the handling of `Ctrl-C` during a test run has been improved to trigger a graceful exit from the test run that reports details of the tests that were run before the interruption.

`BigIntegerField`

Models can now use a 64-bit `BigIntegerField` type.

Improved localization

Django's [internationalization framework](#) has been expanded with locale-aware formatting and form processing. That means, if enabled, dates and numbers on templates will be displayed using the format specified for the current locale. Django will also use localized formats when parsing data in forms. See [Format localization](#) for more details.

`readonly_fields` in `ModelAdmin`

`django.contrib.admin.ModelAdmin.readonly_fields` has been added to enable non-editable fields in add/change pages for models and inlines. Field and calculated values can be displayed alongside editable fields.

Customizable syntax highlighting

You can now use a `DJANGO_COLORS` environment variable to modify or disable the colors used by `django-admin.py` to provide [syntax highlighting](#).

Syndication feeds as views

[Syndication feeds](#) can now be used directly as views in your [URLconf](#). This means that you can maintain complete control over the URL structure of your feeds. Like any other view, feeds views are passed a `request` object, so you can do anything you would normally do with a view, like user based access control, or making a feed a named URL.

GeoDjango

The most significant new feature for [GeoDjango](#) in 1.2 is support for multiple spatial databases. As a result, the following [spatial database backends](#) are now included:

- `django.contrib.gis.db.backends.postgis`
- `django.contrib.gis.db.backends.mysql`
- `django.contrib.gis.db.backends.oracle`
- `django.contrib.gis.db.backends.spatialite`

GeoDjango now supports the rich capabilities added in the PostGIS 1.5 release. New features include support for the [geography type](#) and enabling of [distance queries](#) with non-point geometries on geographic coordinate systems.

Support for 3D geometry fields was added, and may be enabled by setting the `dim` keyword to 3 in your [GeometryField](#). The `Extent3D` aggregate and `extent3d()` `GeoQuerySet` method were added as a part of this feature.

The `force_rhr()`, `reverse_geom()`, and `geohash()` `GeoQuerySet` methods are new.

The GEOS interface was updated to use thread-safe C library functions when available on the platform.

The GDAL interface now allows the user to set a [spatial_filter](#) on the features returned when iterating over a [Layer](#).

Finally, [GeoDjango's documentation](#) is now included with Django's and is no longer hosted separately at [geodjango.org](#).

JavaScript-assisted handling of inline related objects in the admin

If a user has JavaScript enabled in their browser, the interface for inline objects in the admin now allows inline objects to be dynamically added and removed. Users without JavaScript-enabled browsers will see no change in the behavior of inline objects.

New `now` template tag format specifier characters: `c` and `u`

The argument to the `now` has gained two new format characters: `c` to specify that a datetime value should be formatted in ISO 8601 format, and `u` that allows output of the microseconds part of a datetime or time value.

These are also available in others parts like the `date` and `time` template filters, the `humanize` template tag library and the new `format localization` framework.

Backwards-incompatible changes in 1.2

Wherever possible the new features above have been introduced in a backwards-compatible manner per [our API stability policy](#) policy. This means that practically all existing code which worked with Django 1.1 will continue to work with Django 1.2; such code will, however, begin issuing warnings (see below for details).

However, a handful of features have changed in ways that, for some users, will be immediately backwards-incompatible. Those changes are detailed below.

CSRF Protection

We've made large changes to the way CSRF protection works, detailed in [the CSRF documentation](#). Here are the major changes you should be aware of:

- `CsrfResponseMiddleware` and `CsrfMiddleware` have been deprecated and will be removed completely in Django 1.4, in favor of a template tag that should be inserted into forms.
- All contrib apps use a `csrf_protect` decorator to protect the view. This requires the use of the `csrf_token` template tag in the template. If you have used custom templates for contrib views, you **MUST READ THE UPGRADE INSTRUCTIONS** to fix those templates.

Documentation removed

The upgrade notes have been removed in current Django docs. Please refer to the docs for Django 1.3 or older to find these instructions.

- `CsrfViewMiddleware` is included in `MIDDLEWARE_CLASSES` by default. This turns on CSRF protection by default, so views that accept POST requests need to be written to work with the middleware. Instructions on how to do this are found in the CSRF docs.
- All of the CSRF has moved from contrib to core (with backwards compatible imports in the old locations, which are deprecated and will cease to be supported in Django 1.4).

get_db_prep_*() methods on Field

Prior to Django 1.2, a custom Field had the option of defining several functions to support conversion of Python values into database-compatible values. A custom field might look something like:

```
class CustomModelField(models.Field):
    ...

    def db_type(self):
        ...

    def get_db_prep_save(self, value):
        ...

    def get_db_prep_value(self, value):
        ...

    def get_db_prep_lookup(self, lookup_type, value):
        ...
```

In 1.2, these three methods have undergone a change in prototype, and two extra methods have been introduced:

```
class CustomModelField(models.Field):
    ...

    def db_type(self, connection):
        ...

    def get_prep_value(self, value):
        ...

    def get_prep_lookup(self, lookup_type, value):
        ...

    def get_db_prep_save(self, value, connection):
        ...

    def get_db_prep_value(self, value, connection, prepared=False):
        ...

    def get_db_prep_lookup(self, lookup_type, value, connection, prepared=False):
        ...
```

These changes are required to support multiple databases – `db_type` and `get_db_prep_*` can no longer make

any assumptions regarding the database for which it is preparing. The `connection` argument now provides the preparation methods with the specific connection for which the value is being prepared.

The two new methods exist to differentiate general data-preparation requirements from requirements that are database-specific. The `prepared` argument is used to indicate to the database-preparation methods whether generic value preparation has been performed. If an unprepared (i.e., `prepared=False`) value is provided to the `get_db_prep_*()` calls, they should invoke the corresponding `get_prep_*()` calls to perform generic data preparation.

We've provided conversion functions that will transparently convert functions adhering to the old prototype into functions compatible with the new prototype. However, these conversion functions will be removed in Django 1.4, so you should upgrade your `Field` definitions to use the new prototype as soon as possible.

If your `get_db_prep_*()` methods made no use of the database connection, you should be able to upgrade by renaming `get_db_prep_value()` to `get_prep_value()` and `get_db_prep_lookup()` to `get_prep_lookup()`. If you require database specific conversions, then you will need to provide an implementation `get_db_prep_*` that uses the `connection` argument to resolve database-specific values.

Stateful template tags

Template tags that store rendering state on their `Node` subclass have always been vulnerable to thread-safety and other issues; as of Django 1.2, however, they may also cause problems when used with the new [cached template loader](#).

All of the built-in Django template tags are safe to use with the cached loader, but if you're using custom template tags that come from third party packages, or from your own code, you should ensure that the `Node` implementation for each tag is thread-safe. For more information, see [template tag thread safety considerations](#).

You may also need to update your templates if you were relying on the implementation of Django's template tags not being thread safe. The `cycle` tag is the most likely to be affected in this way, especially when used in conjunction with the `include` tag. Consider the following template fragment:

```
{% for object in object_list %}
    {% include "subtemplate.html" %}
{% endfor %}
```

with a `subtemplate.html` that reads:

```
{% cycle 'even' 'odd' %}
```

Using the non-thread-safe, pre-Django 1.2 renderer, this would output:

```
even odd even odd ...
```

Using the thread-safe Django 1.2 renderer, you will instead get:

```
even even even even ...
```

This is because each rendering of the `include` tag is an independent rendering. When the `cycle` tag was not thread safe, the state of the `cycle` tag would leak between multiple renderings of the same `include`. Now that the `cycle` tag is thread safe, this leakage no longer occurs.

`user_passes_test`, `login_required` and `permission_required`

`django.contrib.auth.decorators` provides the decorators `login_required`, `permission_required` and `user_passes_test`. Previously it was possible to use these decorators both on functions (where the first argument is ‘request’) and on methods (where the first argument is ‘self’, and the second argument is ‘request’). Unfortunately, flaws were discovered in the code supporting this: it only works in limited circumstances, and produces errors that are very difficult to debug when it does not work.

For this reason, the ‘auto adapt’ behavior has been removed, and if you are using these decorators on methods, you will need to manually apply `django.utils.decorators.method_decorator()` to convert the decorator to one that works with methods. For example, you would change code from this:

```
class MyClass(object):
    @login_required
    def my_view(self, request):
        pass
```

to this:

```
from django.utils.decorators import method_decorator

class MyClass(object):
    @method_decorator(login_required)
    def my_view(self, request):
        pass
```

or:

```
from django.utils.decorators import method_decorator

login_required_m = method_decorator(login_required)

class MyClass(object):
    @login_required_m
    def my_view(self, request):
        pass
```

For those of you who've been following the development trunk, this change also applies to other decorators introduced since 1.1, including `csrf_protect`, `cache_control` and anything created using `decorator_from_middleware`.

if tag changes

Due to new features in the `if` template tag, it no longer accepts 'and', 'or' and 'not' as valid variable names. Previously, these strings could be used as variable names. Now, the keyword status is always enforced, and template code such as `{% if not %}` or `{% if and %}` will throw a `TemplateSyntaxError`. Also, `in` is a new keyword and so is not a valid variable name in this tag.

LazyObject

`LazyObject` is an undocumented-but-often-used utility class used for lazily wrapping other objects of unknown type.

In Django 1.1 and earlier, it handled introspection in a non-standard way, depending on wrapped objects implementing a public method named `get_all_members()`. Since this could easily lead to name clashes, it has been changed to use the standard Python introspection method, involving `__members__` and `__dir__()`.

If you used `LazyObject` in your own code and implemented the `get_all_members()` method for wrapped objects, you'll need to make a couple of changes:

First, if your class does not have special requirements for introspection (i.e., you have not implemented `__getattr__()` or other methods that allow for attributes not discoverable by normal mechanisms), you can simply remove the `get_all_members()` method. The default implementation on `LazyObject` will do the right thing.

If you have more complex requirements for introspection, first rename the `get_all_members()` method to `__dir__()`. This is the standard introspection method for Python 2.6 and above. If you require support for Python versions earlier than 2.6, add the following code to the class:

```
__members__ = property(lambda self: self.__dir__())
```

__dict__ on model instances

Historically, the `__dict__` attribute of a model instance has only contained attributes corresponding to the fields on a model.

In order to support multiple database configurations, Django 1.2 has added a `_state` attribute to object instances. This attribute will appear in `__dict__` for a model instance. If your code relies on iterating over `__dict__` to obtain a list of fields, you must now be prepared to handle or filter out the `_state` attribute.

Test runner exit status code

The exit status code of the test runners (`tests/runtests.py` and `python manage.py test`) no longer represents the number of failed tests, because a failure of 256 or more tests resulted in a wrong exit status code. The exit status code for the test runner is now 0 for success (no failing tests) and 1 for any number of test failures. If needed, the number of test failures can be found at the end of the test runner's output.

Cookie encoding

To fix bugs with cookies in Internet Explorer, Safari, and possibly other browsers, our encoding of cookie values was changed so that the comma and semicolon are treated as non-safe characters, and are therefore encoded as `\054` and `\073` respectively. This could produce backwards incompatibilities, especially if you are storing comma or semi-colon in cookies and have JavaScript code that parses and manipulates cookie values client-side.

`ModelForm.is_valid()` and `ModelForm.errors`

Much of the validation work for `ModelForms` has been moved down to the model level. As a result, the first time you call `ModelForm.is_valid()`, access `ModelForm.errors` or otherwise trigger form validation, your model will be cleaned in-place. This conversion used to happen when the model was saved. If you need an unmodified instance of your model, you should pass a copy to the `ModelForm` constructor.

`BooleanField` on MySQL

In previous versions of Django, a model's `BooleanField` under MySQL would return its value as either 1 or 0, instead of `True` or `False`; for most people this wasn't a problem because `bool` is a subclass of `int` in Python. In Django 1.2, however, `BooleanField` on MySQL correctly returns a real `bool`. The only time this should ever be an issue is if you were expecting the `repr` of a `BooleanField` to print 1 or 0.

Changes to the interpretation of `max_num` in `FormSets`

As part of enhancements made to the handling of `FormSets`, the default value and interpretation of the `max_num` parameter to the `django.forms.formsets.formset_factory()` and `django.forms.models.modelformset_factory()` functions has changed slightly. This change also affects the way the `max_num` argument is used for inline admin objects.

Previously, the default value for `max_num` was 0 (zero). `FormSets` then used the boolean value of `max_num` to determine if a limit was to be imposed on the number of generated forms. The default value of 0 meant that there was no default limit on the number of forms in a `FormSet`.

Starting with 1.2, the default value for `max_num` has been changed to `None`, and `FormSets` will differentiate between a value of `None` and a value of 0. A value of `None` indicates that no limit on the number of forms is to

be imposed; a value of 0 indicates that a maximum of 0 forms should be imposed. This doesn't necessarily mean that no forms will be displayed –see the [ModelFormSet documentation](#) for more details.

If you were manually specifying a value of 0 for `max_num`, you will need to update your FormSet and/or admin definitions.

See also:

[JavaScript-assisted handling of inline related objects in the admin](#)

`email_re`

An undocumented regular expression for validating email addresses has been moved from `django.form.fields` to `django.core.validators`. You will need to update your imports if you are using it.

Features deprecated in 1.2

Finally, Django 1.2 deprecates some features from earlier releases. These features are still supported, but will be gradually phased out over the next few release cycles.

Code taking advantage of any of the features below will raise a `PendingDeprecationWarning` in Django 1.2. This warning will be silent by default, but may be turned on using Python's `warnings` module, or by running Python with a `-Wd` or `-Wall` flag.

In Django 1.3, these warnings will become a `DeprecationWarning`, which is not silent. In Django 1.4 support for these features will be removed entirely.

See also:

For more details, see the documentation [Django's release process](#) and our [deprecation timeline](#).

Specifying databases

Prior to Django 1.2, Django used a number of settings to control access to a single database. Django 1.2 introduces support for multiple databases, and as a result the way you define database settings has changed.

Any existing Django settings file will continue to work as expected until Django 1.4. Until then, old-style database settings will be automatically translated to the new-style format.

In the old-style (pre 1.2) format, you had a number of `DATABASE_` settings in your settings file. For example:

```
DATABASE_NAME = "test_db"
DATABASE_ENGINE = "postgresql_psycopg2"
DATABASE_USER = "myusername"
DATABASE_PASSWORD = "s3krit"
```

These settings are now in a dictionary named `DATABASES`. Each item in the dictionary corresponds to a single database connection, with the name 'default' describing the default database connection. The setting names have also been shortened. The previous sample settings would now look like this:

```
DATABASES = {
    "default": {
        "NAME": "test_db",
        "ENGINE": "django.db.backends.postgresql_psycopg2",
        "USER": "myusername",
        "PASSWORD": "s3krit",
    }
}
```

This affects the following settings:

Old setting	New Setting
DATABASE_ENGINE	<i>ENGINE</i>
DATABASE_HOST	<i>HOST</i>
DATABASE_NAME	<i>NAME</i>
DATABASE_OPTIONS	<i>OPTIONS</i>
DATABASE_PASSWORD	<i>PASSWORD</i>
DATABASE_PORT	<i>PORT</i>
DATABASE_USER	<i>USER</i>
TEST_DATABASE_CHARSET	<i>TEST_CHARSET</i>
TEST_DATABASE_COLLATION	<i>TEST_COLLATION</i>
TEST_DATABASE_NAME	<i>TEST_NAME</i>

These changes are also required if you have manually created a database connection using `DatabaseWrapper()` from your database backend of choice.

In addition to the change in structure, Django 1.2 removes the special handling for the built-in database backends. All database backends must now be specified by a fully qualified module name (i.e., `django.db.backends.postgresql_psycopg2`, rather than just `postgresql_psycopg2`).

postgresql database backend

The `psycopg1` library has not been updated since October 2005. As a result, the `postgresql` database backend, which uses this library, has been deprecated.

If you are currently using the `postgresql` backend, you should migrate to using the `postgresql_psycopg2` backend. To update your code, install the `psycopg2` library and change the *ENGINE* setting to use `django.db.backends.postgresql_psycopg2`.

CSRF response-rewriting middleware

`CsrfResponseMiddleware`, the middleware that automatically inserted CSRF tokens into POST forms in outgoing pages, has been deprecated in favor of a template tag method (see above), and will be removed completely in Django 1.4. `CsrfMiddleware`, which includes the functionality of `CsrfResponseMiddleware` and `CsrfViewMiddleware`, has likewise been deprecated.

Also, the CSRF module has moved from contrib to core, and the old imports are deprecated, as described in the upgrading notes.

Documentation removed

The upgrade notes have been removed in current Django docs. Please refer to the docs for Django 1.3 or older to find these instructions.

SMTPConnection

The `SMTPConnection` class has been deprecated in favor of a generic email backend API. Old code that explicitly instantiated an instance of an `SMTPConnection`:

```
from django.core.mail import SMTPConnection

connection = SMTPConnection()
messages = get_notification_email()
connection.send_messages(messages)
```

...should now call `get_connection()` to instantiate a generic email connection:

```
from django.core.mail import get_connection

connection = get_connection()
messages = get_notification_email()
connection.send_messages(messages)
```

Depending on the value of the `EMAIL_BACKEND` setting, this may not return an SMTP connection. If you explicitly require an SMTP connection with which to send email, you can explicitly request an SMTP connection:

```
from django.core.mail import get_connection

connection = get_connection("django.core.mail.backends.smtp.EmailBackend")
messages = get_notification_email()
connection.send_messages(messages)
```

If your call to construct an instance of `SMTPConnection` required additional arguments, those arguments can be passed to the `get_connection()` call:

```
connection = get_connection(
    "django.core.mail.backends.smtp.EmailBackend", hostname="localhost", port=1234
)
```

User Messages API

The API for storing messages in the user `Message` model (via `user.message_set.create`) is now deprecated and will be removed in Django 1.4 according to the standard [release process](#).

To upgrade your code, you need to replace any instances of this:

```
user.message_set.create("a message")
```

...with the following:

```
from django.contrib import messages

messages.add_message(request, messages.INFO, "a message")
```

Additionally, if you make use of the method, you need to replace the following:

```
for message in user.get_and_delete_messages():
    ...
```

...with:

```
from django.contrib import messages

for message in messages.get_messages(request):
    ...
```

For more information, see the full [messages documentation](#). You should begin to update your code to use the new API immediately.

Date format helper functions

`django.utils.translation.get_date_formats()` and `django.utils.translation.get_partial_date_formats()` have been deprecated in favor of the appropriate calls to `django.utils.formats.get_format()`, which is locale-aware when `USE_L10N` is set to `True`, and falls back to default settings if set to `False`.

To get the different date formats, instead of writing this:

```
from django.utils.translation import get_date_formats

date_format, datetime_format, time_format = get_date_formats()
```

...use:

```
from django.utils import formats

date_format = formats.get_format("DATE_FORMAT")
datetime_format = formats.get_format("DATETIME_FORMAT")
time_format = formats.get_format("TIME_FORMAT")
```

Or, when directly formatting a date value:

```
from django.utils import formats

value_formatted = formats.date_format(value, "DATETIME_FORMAT")
```

The same applies to the globals found in `django.forms.fields`:

- `DEFAULT_DATE_INPUT_FORMATS`
- `DEFAULT_TIME_INPUT_FORMATS`
- `DEFAULT_DATETIME_INPUT_FORMATS`

Use `django.utils.formats.get_format()` to get the appropriate formats.

Function-based test runners

Django 1.2 changes the test runner tools to use a class-based approach. Old style function-based test runners will still work, but should be updated to use the new [class-based runners](#).

Feed in `django.contrib.syndication.feeds`

The `django.contrib.syndication.feeds.Feed` class has been replaced by the `django.contrib.syndication.views.Feed` class. The old `feeds.Feed` class is deprecated, and will be removed in Django 1.4.

The new class has an almost identical API, but allows instances to be used as views. For example, consider the use of the old framework in the following [URLconf](#):

```
from django.conf.urls.defaults import *
from myproject.feeds import LatestEntries, LatestEntriesByCategory

feeds = {
    "latest": LatestEntries,
    "categories": LatestEntriesByCategory,
}

urlpatterns = patterns(
    "",
    # ...
    (
        r"^feeds/(?P<url>.*)/$",
        "django.contrib.syndication.views.feed",
        {"feed_dict": feeds},
    ),
    # ...
)
```

Using the new `Feed` class, these feeds can be deployed directly as views:

```
from django.conf.urls.defaults import *
from myproject.feeds import LatestEntries, LatestEntriesByCategory

urlpatterns = patterns(
    "",
    # ...
    (r"^feeds/latest/$", LatestEntries()),
    (r"^feeds/categories/(?P<category_id>\d+)/$", LatestEntriesByCategory()),
    # ...
)
```

If you currently use the `feed()` view, the `LatestEntries` class would often not need to be modified apart from subclassing the new `Feed` class. The exception is if Django was automatically working out the name of the template to use to render the feed's description and title elements (if you were not specifying the `title_template` and `description_template` attributes). You should ensure that you

always specify `title_template` and `description_template` attributes, or provide `item_title()` and `item_description()` methods.

However, `LatestEntriesByCategory` uses the `get_object()` method with the `bits` argument to specify a specific category to show. In the new `Feed` class, `get_object()` method takes a `request` and arguments from the URL, so it would look like this:

```
from django.contrib.syndication.views import Feed
from django.shortcuts import get_object_or_404
from myproject.models import Category

class LatestEntriesByCategory(Feed):
    def get_object(self, request, category_id):
        return get_object_or_404(Category, id=category_id)

    # ...
```

Additionally, the `get_feed()` method on `Feed` classes now take different arguments, which may impact you if you use the `Feed` classes directly. Instead of just taking an optional `url` argument, it now takes two arguments: the object returned by its own `get_object()` method, and the current `request` object.

To take into account `Feed` classes not being initialized for each request, the `__init__()` method now takes no arguments by default. Previously it would have taken the `slug` from the URL and the `request` object.

In accordance with [RSS best practices](#), RSS feeds will now include an `atom:link` element. You may need to update your tests to take this into account.

For more information, see the full [syndication framework documentation](#).

Technical message IDs

Up to version 1.1 Django used technical message IDs to provide localizers the possibility to translate date and time formats. They were translatable [translation strings](#) that could be recognized because they were all upper case (for example `DATETIME_FORMAT`, `DATE_FORMAT`, `TIME_FORMAT`). They have been deprecated in favor of the new [Format localization](#) infrastructure that allows localizers to specify that information in a `formats.py` file in the corresponding `django/conf/locale/<locale name>/` directory.

GeoDjango

To allow support for multiple databases, the GeoDjango database internals were changed substantially. The largest backwards-incompatible change is that the module `django.contrib.gis.db.backend` was renamed to `django.contrib.gis.db.backends`, where the full-fledged [spatial database backends](#) now exist. The following sections provide information on the most-popular APIs that were affected by these changes.

SpatialBackend

Prior to the creation of the separate spatial backends, the `django.contrib.gis.db.backend.SpatialBackend` object was provided as an abstraction to introspect on the capabilities of the spatial database. All of the attributes and routines provided by `SpatialBackend` are now a part of the `ops` attribute of the database backend.

The old module `django.contrib.gis.db.backend` is still provided for backwards-compatibility access to a `SpatialBackend` object, which is just an alias to the `ops` module of the default spatial database connection.

Users that were relying on undocumented modules and objects within `django.contrib.gis.db.backend`, rather the abstractions provided by `SpatialBackend`, are required to modify their code. For example, the following import which would work in 1.1 and below:

```
from django.contrib.gis.db.backend.postgis import PostGISAdaptor
```

Would need to be changed:

```
from django.db import connection

PostGISAdaptor = connection.ops.Adapter
```

SpatialRefSys and GeometryColumns models

In previous versions of GeoDjango, `django.contrib.gis.db.models` had `SpatialRefSys` and `GeometryColumns` models for querying the OGC spatial metadata tables `spatial_ref_sys` and `geometry_columns`, respectively.

While these aliases are still provided, they are only for the default database connection and exist only if the default connection is using a supported spatial database backend.

Note: Because the table structure of the OGC spatial metadata tables differs across spatial databases, the `SpatialRefSys` and `GeometryColumns` models can no longer be associated with the `gis` application name. Thus, no models will be returned when using the `get_models` method in the following example:

```
>>> from django.db.models import get_app, get_models
>>> get_models(get_app("gis"))
[]
```

To get the correct `SpatialRefSys` and `GeometryColumns` for your spatial database use the methods provided by the spatial backend:

```
>>> from django.db import connections
>>> SpatialRefSys = connections["my_spatialite"].ops.spatial_ref_sys()
>>> GeometryColumns = connections["my_postgis"].ops.geometry_columns()
```

Note: When using the models returned from the `spatial_ref_sys()` and `geometry_columns()` method, you'll still need to use the correct database alias when querying on the non-default connection. In other words, to ensure that the models in the example above use the correct database:

```
sr_qs = SpatialRefSys.objects.using("my_spatialite").filter(...)
gc_qs = GeometryColumns.objects.using("my_postgis").filter(...)
```

Language code no

The currently used language code for Norwegian Bokmål `no` is being replaced by the more common language code `nb`.

Function-based template loaders

Django 1.2 changes the template loading mechanism to use a class-based approach. Old style function-based template loaders will still work, but should be updated to use the new class-based template loaders.

9.1.20 1.1 release

Django 1.1.4 release notes

Welcome to Django 1.1.4!

This is the fourth “bugfix” release in the Django 1.1 series, improving the stability and performance of the Django 1.1 codebase.

With one exception, Django 1.1.4 maintains backwards compatibility with Django 1.1.3. It also contains a number of fixes and other improvements. Django 1.1.4 is a recommended upgrade for any development or deployment currently using or targeting Django 1.1.

For full details on the new features, backwards incompatibilities, and deprecated features in the 1.1 branch, see the [Django 1.1 release notes](#).

Backwards incompatible changes

CSRF exception for AJAX requests

Django includes a CSRF-protection mechanism, which makes use of a token inserted into outgoing forms. Middleware then checks for the token's presence on form submission, and validates it.

Prior to Django 1.2.5, our CSRF protection made an exception for AJAX requests, on the following basis:

- Many AJAX toolkits add an X-Requested-With header when using XMLHttpRequest.
- Browsers have strict same-origin policies regarding XMLHttpRequest.
- In the context of a browser, the only way that a custom header of this nature can be added is with XMLHttpRequest.

Therefore, for ease of use, we did not apply CSRF checks to requests that appeared to be AJAX on the basis of the X-Requested-With header. The Ruby on Rails web framework had a similar exemption.

Recently, engineers at Google made members of the Ruby on Rails development team aware of a combination of browser plugins and redirects which can allow an attacker to provide custom HTTP headers on a request to any website. This can allow a forged request to appear to be an AJAX request, thereby defeating CSRF protection which trusts the same-origin nature of AJAX requests.

Michael Koziarski of the Rails team brought this to our attention, and we were able to produce a proof-of-concept demonstrating the same vulnerability in Django's CSRF handling.

To remedy this, Django will now apply full CSRF validation to all requests, regardless of apparent AJAX origin. This is technically backwards-incompatible, but the security risks have been judged to outweigh the compatibility concerns in this case.

Additionally, Django will now accept the CSRF token in the custom HTTP header X-CSRFToken, as well as in the form submission itself, for ease of use with popular JavaScript toolkits which allow insertion of custom headers into all AJAX requests.

Please see the [CSRF docs for example jQuery code](#) that demonstrates this technique, ensuring that you are looking at the documentation for your version of Django, as the exact code necessary is different for some older versions of Django.

Django 1.1.3 release notes

Welcome to Django 1.1.3!

This is the third “bugfix” release in the Django 1.1 series, improving the stability and performance of the Django 1.1 codebase.

With one exception, Django 1.1.3 maintains backwards compatibility with Django 1.1.2. It also contains a number of fixes and other improvements. Django 1.1.2 is a recommended upgrade for any development or deployment currently using or targeting Django 1.1.

For full details on the new features, backwards incompatibilities, and deprecated features in the 1.1 branch, see the [Django 1.1 release notes](#).

Backwards incompatible changes

Restricted filters in admin interface

The Django administrative interface, `django.contrib.admin`, supports filtering of displayed lists of objects by fields on the corresponding models, including across database-level relationships. This is implemented by passing lookup arguments in the `querystring` portion of the URL, and options on the `ModelAdmin` class allow developers to specify particular fields or relationships which will generate automatic links for filtering.

One historically-undocumented and -unofficially-supported feature has been the ability for a user with sufficient knowledge of a model’s structure and the format of these lookup arguments to invent useful new filters on the fly by manipulating the `querystring`.

However, it has been demonstrated that this can be abused to gain access to information outside of an admin user’s permissions; for example, an attacker with access to the admin and sufficient knowledge of model structure and relations could construct query strings which –with repeated use of regular-expression lookups supported by the Django database API –expose sensitive information such as users’ password hashes.

To remedy this, `django.contrib.admin` will now validate that `querystring` lookup arguments either specify only fields on the model being viewed, or cross relations which have been explicitly allowed by the application developer using the preexisting mechanism mentioned above. This is backwards-incompatible for any users relying on the prior ability to insert arbitrary lookups.

Django 1.1.2 release notes

Welcome to Django 1.1.2!

This is the second “bugfix” release in the Django 1.1 series, improving the stability and performance of the Django 1.1 codebase.

Django 1.1.2 maintains backwards compatibility with Django 1.1.0, but contain a number of fixes and other improvements. Django 1.1.2 is a recommended upgrade for any development or deployment currently using

or targeting Django 1.1.

For full details on the new features, backwards incompatibilities, and deprecated features in the 1.1 branch, see the [Django 1.1 release notes](#).

Backwards-incompatible changes in 1.1.2

Test runner exit status code

The exit status code of the test runners (`tests/runtests.py` and `python manage.py test`) no longer represents the number of failed tests, since a failure of 256 or more tests resulted in a wrong exit status code. The exit status code for the test runner is now 0 for success (no failing tests) and 1 for any number of test failures. If needed, the number of test failures can be found at the end of the test runner's output.

Cookie encoding

To fix bugs with cookies in Internet Explorer, Safari, and possibly other browsers, our encoding of cookie values was changed so that the characters comma and semi-colon are treated as non-safe characters, and are therefore encoded as `\054` and `\073` respectively. This could produce backwards incompatibilities, especially if you are storing comma or semi-colon in cookies and have JavaScript code that parses and manipulates cookie values client-side.

One new feature

Ordinarily, a point release would not include new features, but in the case of Django 1.1.2, we have made an exception to this rule. Django 1.2 (the next major release of Django) will contain a feature that will improve protection against Cross-Site Request Forgery (CSRF) attacks. This feature requires the use of a new `csrf_token` template tag in all forms that Django renders.

To make it easier to support both 1.1.X and 1.2.X versions of Django with the same templates, we have decided to introduce the `csrf_token` template tag to the 1.1.X branch. In the 1.1.X branch, `csrf_token` does nothing - it has no effect on templates or form processing. However, it means that the same template will work with Django 1.2.

Django 1.1 release notes

July 29, 2009

Welcome to Django 1.1!

Django 1.1 includes a number of nifty [new features](#), lots of bug fixes, and an easy upgrade path from Django 1.0.

Backwards-incompatible changes in 1.1

Django has a policy of [API stability](#). This means that, in general, code you develop against Django 1.0 should continue to work against 1.1 unchanged. However, we do sometimes make backwards-incompatible changes if they're necessary to resolve bugs, and there are a handful of such (minor) changes between Django 1.0 and Django 1.1.

Before upgrading to Django 1.1 you should double-check that the following changes don't impact you, and upgrade your code if they do.

Changes to constraint names

Django 1.1 modifies the method used to generate database constraint names so that names are consistent regardless of machine word size. This change is backwards incompatible for some users.

If you are using a 32-bit platform, you're off the hook; you'll observe no differences as a result of this change.

However, users on 64-bit platforms may experience some problems using the `reset` management command. Prior to this change, 64-bit platforms would generate a 64-bit, 16 character digest in the constraint name; for example:

```
ALTER TABLE myapp_sometable ADD CONSTRAINT object_id_refs_id_5e8f10c132091d1e FOREIGN KEY ...
```

Following this change, all platforms, regardless of word size, will generate a 32-bit, 8 character digest in the constraint name; for example:

```
ALTER TABLE myapp_sometable ADD CONSTRAINT object_id_refs_id_32091d1e FOREIGN KEY ...
```

As a result of this change, you will not be able to use the `reset` management command on any table made by a 64-bit machine. This is because the new generated name will not match the historically generated name; as a result, the SQL constructed by the `reset` command will be invalid.

If you need to reset an application that was created with 64-bit constraints, you will need to manually drop the old constraint prior to invoking `reset`.

Test cases are now run in a transaction

Django 1.1 runs tests inside a transaction, allowing better test performance (see [test performance improvements](#) for details).

This change is slightly backwards incompatible if existing tests need to test transactional behavior, if they rely on invalid assumptions about the test environment, or if they require a specific test case ordering.

For these cases, *TransactionTestCase* can be used instead. This is just a quick fix to get around test case errors revealed by the new rollback approach; in the long-term tests should be rewritten to correct the test case.

Removed `SetRemoteAddrFromForwardedFor` middleware

For convenience, Django 1.0 included an optional middleware class `django.middleware.http.SetRemoteAddrFromForwardedFor` which updated the value of `REMOTE_ADDR` based on the `HTTP X-Forwarded-For` header commonly set by some proxy configurations.

It has been demonstrated that this mechanism cannot be made reliable enough for general-purpose use, and that (despite documentation to the contrary) its inclusion in Django may lead application developers to assume that the value of `REMOTE_ADDR` is “safe” or in some way reliable as a source of authentication.

While not directly a security issue, we’ve decided to remove this middleware with the Django 1.1 release. It has been replaced with a class that does nothing other than raise a `DeprecationWarning`.

If you’ve been relying on this middleware, the easiest upgrade path is:

- Examine the code as it existed before it was removed.
- Verify that it works correctly with your upstream proxy, modifying it to support your particular proxy (if necessary).
- Introduce your modified version of `SetRemoteAddrFromForwardedFor` as a piece of middleware in your own project.

Names of uploaded files are available later

In Django 1.0, files uploaded and stored in a model’s *FileField* were saved to disk before the model was saved to the database. This meant that the actual file name assigned to the file was available before saving. For example, it was available in a model’s pre-save signal handler.

In Django 1.1 the file is saved as part of saving the model in the database, so the actual file name used on disk cannot be relied on until after the model has been saved.

Changes to how model formsets are saved

In Django 1.1, *BaseModelFormSet* now calls `ModelForm.save()`.

This is backwards-incompatible if you were modifying `self.initial` in a model formset’s `__init__`, or if you relied on the internal `_total_form_count` or `_initial_form_count` attributes of `BaseFormSet`. Those attributes are now public methods.

Fixed the `join` filter's escaping behavior

The `join` filter no longer escapes the literal value that is passed in for the connector.

This is backwards incompatible for the special situation of the literal string containing one of the five special HTML characters. Thus, if you were writing `{{ foo|join:"&" }}`, you now have to write `{{ foo|join:"&" }}`.

The previous behavior was a bug and contrary to what was documented and expected.

Permanent redirects and the `redirect_to()` generic view

Django 1.1 adds a `permanent` argument to the `django.views.generic.simple.redirect_to()` view. This is technically backwards-incompatible if you were using the `redirect_to` view with a format-string key called `'permanent'`, which is highly unlikely.

Features deprecated in 1.1

One feature has been marked as deprecated in Django 1.1:

- You should no longer use `AdminSite.root()` to register that admin views. That is, if your `URLconf` contains the line:

```
(r"^admin/(.*)", admin.site.root),
```

You should change it to read:

```
(r"^admin/", include(admin.site.urls)),
```

You should begin to remove use of this feature from your code immediately.

`AdminSite.root` will raise a `PendingDeprecationWarning` if used in Django 1.1. This warning is hidden by default. In Django 1.2, this warning will be upgraded to a `DeprecationWarning`, which will be displayed loudly. Django 1.3 will remove `AdminSite.root()` entirely.

For more details on our deprecation policies and strategy, see [Django's release process](#).

What's new in Django 1.1

Quite a bit: since Django 1.0, we've made 1,290 code commits, fixed 1,206 bugs, and added roughly 10,000 lines of documentation.

The major new features in Django 1.1 are:

ORM improvements

Two major enhancements have been added to Django's object-relational mapper (ORM): aggregate support, and query expressions.

Aggregate support

It's now possible to run SQL aggregate queries (i.e. `COUNT()`, `MAX()`, `MIN()`, etc.) from within Django's ORM. You can choose to either return the results of the aggregate directly, or else annotate the objects in a *QuerySet* with the results of the aggregate query.

This feature is available as new *aggregate()* and *annotate()* methods, and is covered in detail in [the ORM aggregation documentation](#).

Query expressions

Queries can now refer to another field on the query and can traverse relationships to refer to fields on related models. This is implemented in the new *F* object; for full details, including examples, consult the *F expressions documentation*.

Model improvements

A number of features have been added to Django's model layer:

“Unmanaged” models

You can now control whether or not Django manages the life-cycle of the database tables for a model using the *managed* model option. This defaults to `True`, meaning that Django will create the appropriate database tables in `syncdb` and remove them as part of the `reset` command. That is, Django manages the database table's lifecycle.

If you set this to `False`, however, no database table creating or deletion will be automatically performed for this model. This is useful if the model represents an existing table or a database view that has been created by some other means.

For more details, see the documentation for the *managed* option.

Proxy models

You can now create [proxy models](#): subclasses of existing models that only add Python-level (rather than database-level) behavior and aren't represented by a new table. That is, the new model is a proxy for some underlying model, which stores all the real data.

All the details can be found in the [proxy models documentation](#). This feature is similar on the surface to unmanaged models, so the documentation has an explanation of [how proxy models differ from unmanaged models](#).

Deferred fields

In some complex situations, your models might contain fields which could contain a lot of data (for example, large text fields), or require expensive processing to convert them to Python objects. If you know you don't need those particular fields, you can now tell Django not to retrieve them from the database.

You'll do this with the new queryset methods `defer()` and `only()`.

Testing improvements

A few notable improvements have been made to the [testing framework](#).

Test performance improvements

Tests written using Django's [testing framework](#) now run dramatically faster (as much as 10 times faster in many cases).

This was accomplished through the introduction of transaction-based tests: when using `django.test.TestCase`, your tests will now be run in a transaction which is rolled back when finished, instead of by flushing and re-populating the database. This results in an immense speedup for most types of unit tests. See the documentation for `TestCase` and `TransactionTestCase` for a full description, and some important notes on database support.

Test client improvements

A couple of small –but highly useful –improvements have been made to the test client:

- The test `Client` now can automatically follow redirects with the `follow` argument to `Client.get()` and `Client.post()`. This makes testing views that issue redirects simpler.
- It's now easier to get at the template context in the response returned the test client: you'll simply access the context as `request.context[key]`. The old way, which treats `request.context` as a list of contexts, one for each rendered template in the inheritance chain, is still available if you need it.

New admin features

Django 1.1 adds a couple of nifty new features to Django’s admin interface:

Editable fields on the change list

You can now make fields editable on the admin list views via the new `list_editable` admin option. These fields will show up as form widgets on the list pages, and can be edited and saved in bulk.

Admin “actions”

You can now define `admin actions` that can perform some action to a group of models in bulk. Users will be able to select objects on the change list page and then apply these bulk actions to all selected objects.

Django ships with one pre-defined admin action to delete a group of objects in one fell swoop.

Conditional view processing

Django now has much better support for `conditional view processing` using the standard `ETag` and `Last-Modified` HTTP headers. This means you can now easily short-circuit view processing by testing less-expensive conditions. For many views this can lead to a serious improvement in speed and reduction in bandwidth.

URL namespaces

Django 1.1 improves `named URL patterns` with the introduction of URL “namespaces.”

In short, this feature allows the same group of URLs, from the same application, to be included in a Django `URLConf` multiple times, with varying (and potentially nested) named prefixes which will be used when performing reverse resolution. In other words, reusable applications like Django’s admin interface may be registered multiple times without URL conflicts.

For full details, see [the documentation on defining URL namespaces](#).

GeoDjango

In Django 1.1, `GeoDjango` (i.e. `django.contrib.gis`) has several new features:

- Support for `Spatialite` –a spatial database for `SQLite` –as a spatial backend.
- Geographic aggregates (`Collect`, `Extent`, `MakeLine`, `Union`) and `F` expressions.
- New `GeoQuerySet` methods: `collect`, `geojson`, and `snap_to_grid`.

- A new list interface methods for `GEOSGeometry` objects.

For more details, see the [GeoDjango](#) documentation.

Other improvements

Other new features and changes introduced since Django 1.0 include:

- The [CSRF protection middleware](#) has been split into two classes –`CsrfViewMiddleware` checks incoming requests, and `CsrfResponseMiddleware` processes outgoing responses. The combined `CsrfMiddleware` class (which does both) remains for backwards-compatibility, but using the split classes is now recommended in order to allow fine-grained control of when and where the CSRF processing takes place.
- `reverse()` and code which uses it (e.g., the `{% url %}` template tag) now works with URLs in Django’s administrative site, provided that the admin URLs are set up via `include(admin.site.urls)` (sending admin requests to the `admin.site.root` view still works, but URLs in the admin will not be “reversible” when configured this way).
- The `include()` function in Django URLconf modules can now accept sequences of URL patterns (generated by `patterns()`) in addition to module names.
- Instances of Django forms (see [the forms overview](#)) now have two additional methods, `hidden_fields()` and `visible_fields()`, which return the list of hidden –i.e., `<input type="hidden">` –and visible fields on the form, respectively.
- The `redirect_to` generic view now accepts an additional keyword argument `permanent`. If `permanent` is `True`, the view will emit an HTTP permanent redirect (status code 301). If `False`, the view will emit an HTTP temporary redirect (status code 302).
- A new database lookup type –`week_day` –has been added for `DateField` and `DateTimeField`. This type of lookup accepts a number between 1 (Sunday) and 7 (Saturday), and returns objects where the field value matches that day of the week. See [the full list of lookup types](#) for details.
- The `{% for %}` tag in Django’s template language now accepts an optional `{% empty %}` clause, to be displayed when `{% for %}` is asked to loop over an empty sequence. See [the list of built-in template tags](#) for examples of this.
- The `dumpdata` management command now accepts individual model names as arguments, allowing you to export the data just from particular models.
- There’s a new `safeseq` template filter which works just like `safe` for lists, marking each item in the list as safe.
- [Cache backends](#) now support `incr()` and `decr()` commands to increment and decrement the value of a cache key. On cache backends that support atomic increment/decrement –most notably, the memcached backend –these operations will be atomic, and quite fast.

- Django now can [easily delegate authentication to the web server](#) via a new authentication backend that supports the standard `REMOTE_USER` environment variable used for this purpose.
- There's a new `django.shortcuts.redirect()` function that makes it easier to issue redirects given an object, a view name, or a URL.
- The `postgresql_psycopg2` backend now supports [native PostgreSQL autocommit](#). This is an advanced, PostgreSQL-specific feature, that can make certain read-heavy applications a good deal faster.

What's next?

We'll take a short break, and then work on Django 1.2 will begin –no rest for the weary! If you'd like to help, discussion of Django development, including progress toward the 1.2 release, takes place daily on the [django-developers](#) mailing list and in the `#django-dev` IRC channel on `irc.libera.chat`. Feel free to join the discussions!

Django's online documentation also includes pointers on how to contribute to Django:

- [How to contribute to Django](#)

Contributions on any level –developing code, writing documentation or simply triaging tickets and helping to test proposed bugfixes –are always welcome and appreciated.

And that's the way it is.

9.1.21 1.0 release

Django 1.0.2 release notes

Welcome to Django 1.0.2!

This is the second “bugfix” release in the Django 1.0 series, improving the stability and performance of the Django 1.0 codebase. As such, Django 1.0.2 contains no new features (and, pursuant to [our compatibility policy](#), maintains backwards compatibility with Django 1.0.0), but does contain a number of fixes and other improvements. Django 1.0.2 is a recommended upgrade for any development or deployment currently using or targeting Django 1.0.

Fixes and improvements in Django 1.0.2

The primary reason behind this release is to remedy an issue in the recently-released Django 1.0.1; the packaging scripts used for Django 1.0.1 omitted some directories from the final release package, including one directory required by `django.contrib.gis` and part of Django's unit-test suite.

Django 1.0.2 contains updated packaging scripts, and the release package contains the directories omitted from Django 1.0.1. As such, this release contains all of the fixes and improvements from Django 1.0.1; see [the Django 1.0.1 release notes](#) for details.

Additionally, in the period since Django 1.0.1 was released:

- Updated Hebrew and Danish translations have been added.
- The default `__repr__` method of Django models has been made more robust in the face of bad Unicode data coming from the `__unicode__` method; rather than raise an exception in such cases, `repr()` will now contain the string “[Bad Unicode data]” in place of the invalid Unicode.
- A bug involving the interaction of Django’s `SafeUnicode` class and the MySQL adapter has been resolved; `SafeUnicode` instances (generated, for example, by template rendering) can now be assigned to model attributes and saved to MySQL without requiring an explicit intermediate cast to `unicode`.
- A bug affecting filtering on a nullable `DateField` in SQLite has been resolved.
- Several updates and improvements have been made to Django’s documentation.

Django 1.0.1 release notes

Welcome to Django 1.0.1!

This is the first “bugfix” release in the Django 1.0 series, improving the stability and performance of the Django 1.0 codebase. As such, Django 1.0.1 contains no new features (and, pursuant to [our compatibility policy](#), maintains backwards compatibility with Django 1.0), but does contain a number of fixes and other improvements. Django 1.0.1 is a recommended upgrade for any development or deployment currently using or targeting Django 1.0.

Fixes and improvements in Django 1.0.1

Django 1.0.1 contains over two hundred fixes to the original Django 1.0 codebase; full details of every fix are available in [the history of the 1.0.X branch](#), but here are some of the highlights:

- Several fixes in `django.contrib.comments`, pertaining to RSS feeds of comments, default ordering of comments and the XHTML and internationalization of the default templates for comments.
- Multiple fixes for Django’s support of Oracle databases, including pagination support for GIS Query-Sets, more efficient slicing of results and improved introspection of existing databases.
- Several fixes for query support in the Django object-relational mapper, including repeated setting and resetting of ordering and fixes for working with INSERT-only queries.
- Multiple fixes for inline forms in formsets.
- Multiple fixes for `unique` and `unique_together` model constraints in automatically-generated forms.
- Fixed support for custom callable `upload_to` declarations when handling file uploads through automatically-generated forms.
- Fixed support for sorting an admin change list based on a callable attributes in `list_display`.

- A fix to the application of autoescaping for literal strings passed to the `join` template filter. Previously, literal strings passed to `join` were automatically escaped, contrary to [the documented behavior for autoescaping and literal strings](#). Literal strings passed to `join` are no longer automatically escaped, meaning you must now manually escape them; this is an incompatibility if you were relying on this bug, but not if you were relying on escaping behaving as documented.
- Improved and expanded translation files for many of the languages Django supports by default.
- And as always, a large number of improvements to Django's documentation, including both corrections to existing documents and expanded and new documentation.

Django 1.0 release notes

Welcome to Django 1.0!

We've been looking forward to this moment for over three years, and it's finally here. Django 1.0 represents the largest milestone in Django's development to date: a web framework that a group of perfectionists can truly be proud of.

Django 1.0 represents over three years of community development as an Open Source project. Django's received contributions from hundreds of developers, been translated into fifty languages, and today is used by developers on every continent and in every kind of job.

An interesting historical note: when Django was first released in July 2005, the initial released version of Django came from an internal repository at revision number 8825. Django 1.0 represents revision 8961 of our public repository. It seems fitting that our 1.0 release comes at the moment where community contributions overtake those made privately.

Stability and forwards-compatibility

The release of Django 1.0 comes with a promise of API stability and forwards-compatibility. In a nutshell, this means that code you develop against Django 1.0 will continue to work against 1.1 unchanged, and you should need to make only minor changes for any 1.X release.

See the [API stability guide](#) for full details.

Backwards-incompatible changes

Django 1.0 has a number of backwards-incompatible changes from Django 0.96. If you have apps written against Django 0.96 that you need to port, see our detailed porting guide:

Porting your apps from Django 0.96 to 1.0

Django 1.0 breaks compatibility with 0.96 in some areas.

This guide will help you port 0.96 projects and apps to 1.0. The first part of this document includes the common changes needed to run with 1.0. If after going through the first part your code still breaks, check the section [Less-common Changes](#) for a list of a bunch of less-common compatibility issues.

See also:

The [1.0 release notes](#). That document explains the new features in 1.0 more deeply; the porting guide is more concerned with helping you quickly update your code.

Common changes

This section describes the changes between 0.96 and 1.0 that most users will need to make.

Use Unicode

Change string literals (`'foo'`) into Unicode literals (`u'foo'`). Django now uses Unicode strings throughout. In most places, raw strings will continue to work, but updating to use Unicode literals will prevent some obscure problems.

See [Unicode data](#) for full details.

Models

Common changes to your models file:

Rename `maxlength` to `max_length`

Rename your `maxlength` argument to `max_length` (this was changed to be consistent with form fields):

Replace `__str__` with `__unicode__`

Replace your model's `__str__` function with a `__unicode__` method, and make sure you [use Unicode](#) (`u'foo'`) in that method.

Remove `prepopulated_from`

Remove the `prepopulated_from` argument on model fields. It's no longer valid and has been moved to the `ModelAdmin` class in `admin.py`. See [the admin](#), below, for more details about changes to the admin.

Remove `core`

Remove the `core` argument from your model fields. It is no longer necessary, since the equivalent functionality (part of [inline editing](#)) is handled differently by the admin interface now. You don't have to worry about inline editing until you get to [the admin](#) section, below. For now, remove all references to `core`.

Replace `class Admin:` with `admin.py`

Remove all your inner `class Admin` declarations from your models. They won't break anything if you leave them, but they also won't do anything. To register apps with the admin you'll move those declarations to an `admin.py` file; see [the admin](#) below for more details.

See also:

A contributor to [djangosnippets](#) has written a script that'll scan your `models.py` and generate a corresponding `admin.py`.

Example

Below is an example `models.py` file with all the changes you'll need to make:

Old (0.96) `models.py`:

```
class Author(models.Model):
    first_name = models.CharField(maxlength=30)
    last_name = models.CharField(maxlength=30)
    slug = models.CharField(maxlength=60, prepopulate_from=("first_name", "last_name"))

    class Admin:
        list_display = ["first_name", "last_name"]

    def __str__(self):
        return "%s %s" % (self.first_name, self.last_name)
```

New (1.0) `models.py`:

```
class Author(models.Model):
    first_name = models.CharField(max_length=30)
```

(continues on next page)

(continued from previous page)

```
last_name = models.CharField(max_length=30)
slug = models.CharField(max_length=60)

def __unicode__(self):
    return "%s %s" % (self.first_name, self.last_name)
```

New (1.0) admin.py:

```
from django.contrib import admin
from models import Author

class AuthorAdmin(admin.ModelAdmin):
    list_display = ["first_name", "last_name"]
    prepopulated_fields = {"slug": ("first_name", "last_name")}

admin.site.register(Author, AuthorAdmin)
```

The Admin

One of the biggest changes in 1.0 is the new admin. The Django administrative interface (`django.contrib.admin`) has been completely refactored; admin definitions are now completely decoupled from model definitions, the framework has been rewritten to use Django's new form-handling library and redesigned with extensibility and customization in mind.

Practically, this means you'll need to rewrite all of your `class Admin` declarations. You've already seen in [models](#) above how to replace your `class Admin` with an `admin.site.register()` call in an `admin.py` file. Below are some more details on how to rewrite that `Admin` declaration into the new syntax.

Use new inline syntax

The new `edit_inline` options have all been moved to `admin.py`. Here's an example:

Old (0.96):

```
class Parent(models.Model):
    ...

class Child(models.Model):
    parent = models.ForeignKey(Parent, edit_inline=models.STACKED, num_in_admin=3)
```

New (1.0):

```
class ChildInline(admin.StackedInline):
    model = Child
    extra = 3

class ParentAdmin(admin.ModelAdmin):
    model = Parent
    inlines = [ChildInline]

admin.site.register(Parent, ParentAdmin)
```

See [InlineModelAdmin](#) objects for more details.

Simplify fields, or use fieldsets

The old `fields` syntax was quite confusing, and has been simplified. The old syntax still works, but you'll need to use `fieldsets` instead.

Old (0.96):

```
class ModelOne(models.Model):
    ...

    class Admin:
        fields = ((None, {"fields": ("foo", "bar")}),)

class ModelTwo(models.Model):
    ...

    class Admin:
        fields = (
            ("group1", {"fields": ("foo", "bar"), "classes": "collapse"}),
            ("group2", {"fields": ("spam", "eggs"), "classes": "collapse wide"}),
        )
```

New (1.0):

```
class ModelOneAdmin(admin.ModelAdmin):
    fields = ("foo", "bar")
```

(continues on next page)

(continued from previous page)

```
class ModelTwoAdmin(admin.ModelAdmin):
    fieldsets = (
        ("group1", {"fields": ("foo", "bar"), "classes": "collapse"}),
        ("group2", {"fields": ("spam", "eggs"), "classes": "collapse wide"}),
    )
```

See also:

- More detailed information about the changes and the reasons behind them can be found on the [New-formsAdminBranch](#) wiki page
- The new admin comes with a ton of new features; you can read about them in the [admin documentation](#).

URLs

Update your root `urls.py`

If you're using the admin site, you need to update your root `urls.py`.

Old (0.96) `urls.py`:

```
from django.conf.urls.defaults import *

urlpatterns = patterns(
    "",
    (r"^admin/", include("django.contrib.admin.urls")),
    # ... the rest of your URLs here ...
)
```

New (1.0) `urls.py`:

```
from django.conf.urls.defaults import *

# The next two lines enable the admin and load each admin.py file:
from django.contrib import admin

admin.autodiscover()

urlpatterns = patterns(
    "",
    (r"^admin/(.*)", admin.site.root),
    # ... the rest of your URLs here ...
)
```

Views

Use `django.forms` instead of `newforms`

Replace `django.newforms` with `django.forms` –Django 1.0 renamed the `newforms` module (introduced in 0.96) to plain old `forms`. The `oldforms` module was also removed.

If you’re already using the `newforms` library, and you used our recommended `import` statement syntax, all you have to do is change your import statements.

Old:

```
from django import newforms as forms
```

New:

```
from django import forms
```

If you’re using the old forms system (formerly known as `django.forms` and `django.oldforms`), you’ll have to rewrite your forms. A good place to start is the [forms documentation](#)

Handle uploaded files using the new API

Replace use of uploaded files –that is, entries in `request.FILES` –as simple dictionaries with the new *UploadedFile*. The old dictionary syntax no longer works.

Thus, in a view like:

```
def my_view(request):
    f = request.FILES["file_field_name"]
    ...
```

...you’d need to make the following changes:

Old (0.96)	New (1.0)
<code>f['content']</code>	<code>f.read()</code>
<code>f['filename']</code>	<code>f.name</code>
<code>f['content-type']</code>	<code>f.content_type</code>

Work with file fields using the new API

The internal implementation of `django.db.models.FileField` have changed. A visible result of this is that the way you access special attributes (URL, filename, image size, etc.) of these model fields has changed. You will need to make the following changes, assuming your model's `FileField` is called `myfile`:

Old (0.96)	New (1.0)
<code>myfile.get_content_filename()</code>	<code>myfile.content.path</code>
<code>myfile.get_content_url()</code>	<code>myfile.content.url</code>
<code>myfile.get_content_size()</code>	<code>myfile.content.size</code>
<code>myfile.save_content_file()</code>	<code>myfile.content.save()</code>
<code>myfile.get_content_width()</code>	<code>myfile.content.width</code>
<code>myfile.get_content_height()</code>	<code>myfile.content.height</code>

Note that the `width` and `height` attributes only make sense for `ImageField` fields. More details can be found in the [model API](#) documentation.

Use Paginator instead of ObjectPaginator

The `ObjectPaginator` in 0.96 has been removed and replaced with an improved version, `django.core.paginator.Paginator`.

Templates

Learn to love autoescaping

By default, the template system now automatically HTML-escapes the output of every variable. To learn more, see [Automatic HTML escaping](#).

To disable auto-escaping for an individual variable, use the `safe` filter:

```
This will be escaped: {{ data }}
This will not be escaped: {{ data|safe }}
```

To disable auto-escaping for an entire template, wrap the template (or just a particular section of the template) in the `autoescape` tag:

```
{% autoescape off %}
... unescaped template content here ...
{% endautoescape %}
```

Less-common changes

The following changes are smaller, more localized changes. They should only affect more advanced users, but it's probably worth reading through the list and checking your code for these things.

Signals

- Add `**kwargs` to any registered signal handlers.
- Connect, disconnect, and send signals via methods on the `Signal` object instead of through module methods in `django.dispatch.dispatcher`.
- Remove any use of the `Anonymous` and `Any` sender options; they no longer exist. You can still receive signals sent by any sender by using `sender=None`
- Make any custom signals you've declared into instances of `django.dispatch.Signal` instead of anonymous objects.

Here's quick summary of the code changes you'll need to make:

Old (0.96)	New (1.0)
<code>def callback(sender)</code>	<code>def callback(sender, **kwargs)</code>
<code>sig = object()</code>	<code>sig = django.dispatch.Signal()</code>
<code>dispatcher.connect(callback, sig)</code>	<code>sig.connect(callback)</code>
<code>dispatcher.send(sig, sender)</code>	<code>sig.send(sender)</code>
<code>dispatcher.connect(callback, sig, sender=Any)</code>	<code>sig.connect(callback, sender=None)</code>

Comments

If you were using Django 0.96's `django.contrib.comments` app, you'll need to upgrade to the new comments app introduced in 1.0. See the upgrade guide for details.

Template tags

spaceless tag

The `spaceless` template tag now removes all spaces between HTML tags, instead of preserving a single space.

Local flavors

U.S. local flavor

`django.contrib.localflavor.usa` has been renamed to `django.contrib.localflavor.us`. This change was made to match the naming scheme of other local flavors. To migrate your code, all you need to do is change the imports.

Sessions

Getting a new session key

`SessionBase.get_new_session_key()` has been renamed to `_get_new_session_key()`. `get_new_session_object()` no longer exists.

Fixtures

Loading a row no longer calls `save()`

Previously, loading a row automatically ran the model's `save()` method. This is no longer the case, so any fields (for example: timestamps) that were auto-populated by a `save()` now need explicit values in any fixture.

Settings

Better exceptions

The old `EnvironmentError` has split into an `ImportError` when Django fails to find the settings module and a `RuntimeError` when you try to reconfigure settings after having already used them.

LOGIN_URL has moved

The `LOGIN_URL` constant moved from `django.contrib.auth` into the `settings` module. Instead of using `from django.contrib.auth import LOGIN_URL` refer to `settings.LOGIN_URL`.

APPEND_SLASH behavior has been updated

In 0.96, if a URL didn't end in a slash or have a period in the final component of its path, and `APPEND_SLASH` was True, Django would redirect to the same URL, but with a slash appended to the end. Now, Django checks to see whether the pattern without the trailing slash would be matched by something in your URL patterns. If so, no redirection takes place, because it is assumed you deliberately wanted to catch that pattern.

For most people, this won't require any changes. Some people, though, have URL patterns that look like this:

```
r"/some_prefix/(.*)$"
```

Previously, those patterns would have been redirected to have a trailing slash. If you always want a slash on such URLs, rewrite the pattern as:

```
r"/some_prefix/(.*)/$"
```

Smaller model changes

Different exception from `get()`

Managers now return a *MultipleObjectsReturned* exception instead of `AssertionError`:

Old (0.96):

```
try:
    Model.objects.get(...)
except AssertionError:
    handle_the_error()
```

New (1.0):

```
try:
    Model.objects.get(...)
except Model.MultipleObjectsReturned:
    handle_the_error()
```

LazyDate has been fired

The `LazyDate` helper class no longer exists.

Default field values and query arguments can both be callable objects, so instances of `LazyDate` can be replaced with a reference to `datetime.datetime.now`:

Old (0.96):

```
class Article(models.Model):
    title = models.CharField(maxlength=100)
    published = models.DateField(default=LazyDate())
```

New (1.0):

```
import datetime

class Article(models.Model):
    title = models.CharField(max_length=100)
    published = models.DateField(default=datetime.datetime.now)
```

DecimalField is new, and FloatField is now a proper float

Old (0.96):

```
class MyModel(models.Model):
    field_name = models.FloatField(max_digits=10, decimal_places=3)
    ...
```

New (1.0):

```
class MyModel(models.Model):
    field_name = models.DecimalField(max_digits=10, decimal_places=3)
    ...
```

If you forget to make this change, you will see errors about `FloatField` not taking a `max_digits` attribute in `__init__`, because the new `FloatField` takes no precision-related arguments.

If you're using MySQL or PostgreSQL, no further changes are needed. The database column types for `DecimalField` are the same as for the old `FloatField`.

If you're using SQLite, you need to force the database to view the appropriate columns as decimal types, rather than floats. To do this, you'll need to reload your data. Do this after you have made the change to using `DecimalField` in your code and updated the Django code.

Warning: Back up your database first!

For SQLite, this means making a copy of the single file that stores the database (the name of that file is the `DATABASE_NAME` in your `settings.py` file).

To upgrade each application to use a `DecimalField`, you can do the following, replacing `<app>` in the code below with each app's name:

```
$ ./manage.py dumpdata --format=xml <app> > data-dump.xml
$ ./manage.py reset <app>
$ ./manage.py loaddata data-dump.xml
```

Notes:

1. It's important that you remember to use XML format in the first step of this process. We are exploiting a feature of the XML data dumps that makes porting floats to decimals with SQLite possible.
2. In the second step you will be asked to confirm that you are prepared to lose the data for the application(s) in question. Say yes; we'll restore this data in the third step.
3. `DecimalField` is not used in any of the apps shipped with Django prior to this change being made, so you do not need to worry about performing this procedure for any of the standard Django models.

If something goes wrong in the above process, just copy your backed up database file over the original file and start again.

Internationalization

`django.views.i18n.set_language()` now requires a POST request

Previously, a GET request was used. The old behavior meant that state (the locale used to display the site) could be changed by a GET request, which is against the HTTP specification's recommendations. Code calling this view must ensure that a POST request is now made, instead of a GET. This means you can no longer use a link to access the view, but must use a form submission of some kind (e.g. a button).

`_()` is no longer in builtins

`_()` (the callable object whose name is a single underscore) is no longer monkeypatched into builtins—that is, it's no longer available magically in every module.

If you were previously relying on `_()` always being present, you should now explicitly import `ugettext` or `ugettext_lazy`, if appropriate, and alias it to `_` yourself:

```
from django.utils.translation import ugettext as _
```

HTTP request/response objects

Dictionary access to HttpRequest

`HttpRequest` objects no longer directly support dictionary-style access; previously, both GET and POST data were directly available on the `HttpRequest` object (e.g., you could check for a piece of form data by using `if 'some_form_key' in request` or by reading `request['some_form_key']`). This is no longer supported; if you need access to the combined GET and POST data, use `request.REQUEST` instead.

It is strongly suggested, however, that you always explicitly look in the appropriate dictionary for the type of request you expect to receive (`request.GET` or `request.POST`); relying on the combined `request.REQUEST` dictionary can mask the origin of incoming data.

Accessing HttpResponse headers

`django.http.HttpResponse.headers` has been renamed to `_headers` and *`HttpResponse`* now supports containment checking directly. So use `if header in response:` instead of `if header in response.headers:`.

Generic relations

Generic relations have been moved out of core

The generic relation classes `GenericForeignKey` and `GenericRelation` have moved into the *`django.contrib.contenttypes`* module.

Testing

`django.test.Client.login()` has changed

Old (0.96):

```
from django.test import Client

c = Client()
c.login("/path/to/login", "myuser", "mypassword")
```

New (1.0):

```
# ... same as above, but then:
c.login(username="myuser", password="mypassword")
```

Management commands

Running management commands from your code

`django.core.management` has been greatly refactored.

Calls to management services in your code now need to use `call_command`. For example, if you have some test code that calls `flush` and `load_data`:

```
from django.core import management

management.flush(verbosity=0, interactive=False)
management.load_data(["test_data"], verbosity=0)
```

...you'll need to change this code to read:

```
from django.core import management

management.call_command("flush", verbosity=0, interactive=False)
management.call_command("loaddata", "test_data", verbosity=0)
```

Subcommands must now precede options

`django-admin.py` and `manage.py` now require subcommands to precede options. So:

```
$ django-admin.py --settings=foo.bar runserver
```

...no longer works and should be changed to:

```
$ django-admin.py runserver --settings=foo.bar
```

Syndication

`Feed.__init__` has changed

The `__init__()` method of the syndication framework's `Feed` class now takes an `HttpRequest` object as its second parameter, instead of the feed's URL. This allows the syndication framework to work without requiring the sites framework. This only affects code that subclasses `Feed` and overrides the `__init__()` method, and code that calls `Feed.__init__()` directly.

Data structures

SortedDictFromList is gone

`django.newforms.forms.SortedDictFromList` was removed. `django.utils.datastructures.SortedDict` can now be instantiated with a sequence of tuples.

To update your code:

1. Use `django.utils.datastructures.SortedDict` wherever you were using `django.newforms.forms.SortedDictFromList`.
2. Because `django.utils.datastructures.SortedDict.copy` doesn't return a deepcopy as `SortedDictFromList.copy()` did, you will need to update your code if you were relying on a deepcopy. Do this by using `copy.deepcopy` directly.

Database backend functions

Database backend functions have been renamed

Almost all of the database backend-level functions have been renamed and/or relocated. None of these were documented, but you'll need to change your code if you're using any of these functions, all of which are in *django.db*:

Old (0.96)	New (1.0)
<code>backend.get_autoinc_sql</code>	<code>connection.ops.autoinc_sql</code>
<code>backend.get_date_extract_sql</code>	<code>connection.ops.date_extract_sql</code>
<code>backend.get_date_trunc_sql</code>	<code>connection.ops.date_trunc_sql</code>
<code>backend.get_datetime_cast_sql</code>	<code>connection.ops.datetime_cast_sql</code>
<code>backend.get_deferrable_sql</code>	<code>connection.ops.deferrable_sql</code>
<code>backend.get_drop_foreignkey_sql</code>	<code>connection.ops.drop_foreignkey_sql</code>
<code>backend.get_fulltext_search_sql</code>	<code>connection.ops.fulltext_search_sql</code>
<code>backend.get_last_insert_id</code>	<code>connection.ops.last_insert_id</code>
<code>backend.get_limit_offset_sql</code>	<code>connection.ops.limit_offset_sql</code>
<code>backend.get_max_name_length</code>	<code>connection.ops.max_name_length</code>
<code>backend.get_pk_default_value</code>	<code>connection.ops.pk_default_value</code>
<code>backend.get_random_function_sql</code>	<code>connection.ops.random_function_sql</code>
<code>backend.get_sql_flush</code>	<code>connection.ops.sql_flush</code>
<code>backend.get_sql_sequence_reset</code>	<code>connection.ops.sequence_reset_sql</code>
<code>backend.get_start_transaction_sql</code>	<code>connection.ops.start_transaction_sql</code>
<code>backend.get_tablespace_sql</code>	<code>connection.ops.tablespace_sql</code>

continues on next page

Table 1 – continued from previous page

Old (0.96)	New (1.0)
<code>backend.quote_name</code>	<code>connection.ops.quote_name</code>
<code>backend.get_query_set_class</code>	<code>connection.ops.query_set_class</code>
<code>backend.get_field_cast_sql</code>	<code>connection.ops.field_cast_sql</code>
<code>backend.get_drop_sequence</code>	<code>connection.ops.drop_sequence_sql</code>
<code>backend.OPERATOR_MAPPING</code>	<code>connection.operators</code>
<code>backend.allows_group_by_ordinal</code>	<code>connection.features.allows_group_by_ordinal</code>
<code>backend.allows_unique_and_pk</code>	<code>connection.features.allows_unique_and_pk</code>

<code>backend.uses_case_insensitive_names</code>	<code>connection.features.uses_case_insensitive_names</code>
<code>backend.uses_custom_queryset</code>	<code>connection.features.uses_custom_queryset</code>

A complete list of backwards-incompatible changes can be found at <https://code.djangoproject.com/wiki/BackwardsIncompatibleChanges>.

What’s new in Django 1.0

A lot!

Since Django 0.96, we’ve made over 4,000 code commits, fixed more than 2,000 bugs, and edited, added, or removed around 350,000 lines of code. We’ve also added 40,000 lines of new documentation, and greatly improved what was already there.

In fact, new documentation is one of our favorite features of Django 1.0, so we might as well start there. First, there’s a new documentation site:

- <https://docs.djangoproject.com/>

The documentation has been greatly improved, cleaned up, and generally made awesome. There’s now dedicated search, indexes, and more.

We can’t possibly document everything that’s new in 1.0, but the documentation will be your definitive guide. Anywhere you see something like:

This feature is new in Django 1.0

You’ll know that you’re looking at something new or changed.

The other major highlights of Django 1.0 are:

Refactored admin application

The Django administrative interface (`django.contrib.admin`) has been completely refactored; admin definitions are now completely decoupled from model definitions (no more `class Admin` declaration in models!), rewritten to use Django's new form-handling library (introduced in the 0.96 release as `django.newforms`, and now available as simply `django.forms`) and redesigned with extensibility and customization in mind. Full documentation for the admin application is available online in the official Django documentation:

See the [admin reference](#) for details

Improved Unicode handling

Django's internals have been refactored to use Unicode throughout; this drastically simplifies the task of dealing with non-Western-European content and data in Django. Additionally, utility functions have been provided to ease interoperability with third-party libraries and systems which may or may not handle Unicode gracefully. Details are available in Django's Unicode-handling documentation.

See [Unicode data](#).

An improved ORM

Django's object-relational mapper –the component which provides the mapping between Django model classes and your database, and which mediates your database queries –has been dramatically improved by a massive refactoring. For most users of Django this is backwards-compatible; the public-facing API for database querying underwent a few minor changes, but most of the updates took place in the ORM's internals. A guide to the changes, including backwards-incompatible modifications and mentions of new features opened up by this refactoring, is [available on the Django wiki](#).

Automatic escaping of template variables

To provide improved security against cross-site scripting (XSS) vulnerabilities, Django's template system now automatically escapes the output of variables. This behavior is configurable, and allows both variables and larger template constructs to be marked as safe (requiring no escaping) or unsafe (requiring escaping). A full guide to this feature is in the documentation for the [`autoescape`](#) tag.

`django.contrib.gis` (GeoDjango)

A project over a year in the making, this adds world-class GIS (Geographic Information Systems) support to Django, in the form of a `contrib` application. Its documentation is currently being maintained externally, and will be merged into the main Django documentation shortly. Huge thanks go to Justin Bronn, Jeremy Dunck, Brett Hoerner and Travis Pinney for their efforts in creating and completing this feature.

See [GeoDjango](#) for details.

Pluggable file storage

Django's built-in `FileField` and `ImageField` now can take advantage of pluggable file-storage backends, allowing extensive customization of where and how uploaded files get stored by Django. For details, see [the files documentation](#); big thanks go to Marty Alchin for putting in the hard work to get this completed.

Jython compatibility

Thanks to a lot of work from Leo Soto during a Google Summer of Code project, Django's codebase has been refactored to remove incompatibilities with [Jython](#), an implementation of Python written in Java, which runs Python code on the Java Virtual Machine. Django is now compatible with the forthcoming Jython 2.5 release.

Generic relations in forms and admin

Classes are now included in `django.contrib.contenttypes` which can be used to support generic relations in both the admin interface and in end-user forms. See [the documentation for generic relations](#) for details.

INSERT/UPDATE distinction

Although Django's default behavior of having a model's `save()` method automatically determine whether to perform an INSERT or an UPDATE at the SQL level is suitable for the majority of cases, there are occasional situations where forcing one or the other is useful. As a result, models can now support an additional parameter to `save()` which can force a specific operation.

See [Forcing an INSERT or UPDATE](#) for details.

Split CacheMiddleware

Django's `CacheMiddleware` has been split into three classes: `CacheMiddleware` itself still exists and retains all of its previous functionality, but it is now built from two separate middleware classes which handle the two parts of caching (inserting into and reading from the cache) separately, offering additional flexibility for situations where combining these functions into a single middleware posed problems.

Full details, including updated notes on appropriate use, are in [the caching documentation](#).

Refactored `django.contrib.comments`

As part of a Google Summer of Code project, Thejaswi Puthraya carried out a major rewrite and refactoring of Django's bundled comment system, greatly increasing its flexibility and customizability.

Removal of deprecated features

A number of features and methods which had previously been marked as deprecated, and which were scheduled for removal prior to the 1.0 release, are no longer present in Django. These include imports of the form library from `django.newforms` (now located simply at `django.forms`), the `form_for_model` and `form_for_instance` helper functions (which have been replaced by `ModelForm`) and a number of deprecated features which were replaced by the dispatcher, file-uploading and file-storage refactoring introduced in the Django 1.0 alpha releases.

Known issues

We've done our best to make Django 1.0 as solid as possible, but unfortunately there are a couple of issues that we know about in the release.

Multi-table model inheritance with `to_field`

If you're using [multiple table model inheritance](#), be aware of this caveat: child models using a custom `parent_link` and `to_field` will cause database integrity errors. A set of models like the following are not valid:

```
class Parent(models.Model):
    name = models.CharField(max_length=10)
    other_value = models.IntegerField(unique=True)

class Child(Parent):
    father = models.OneToOneField(
```

(continues on next page)

(continued from previous page)

```
Parent, primary_key=True, to_field="other_value", parent_link=True
)
value = models.IntegerField()
```

This bug will be fixed in the next release of Django.

Caveats with support of certain databases

Django attempts to support as many features as possible on all database backends. However, not all database backends are alike, and in particular many of the supported database differ greatly from version to version. It's a good idea to checkout our [notes on supported database](#):

- [MySQL notes](#)
- [SQLite notes](#)
- [Oracle notes](#)

9.1.22 Pre-1.0 releases

Django version 0.96 release notes

Welcome to Django 0.96!

The primary goal for 0.96 is a cleanup and stabilization of the features introduced in 0.95. There have been a few small [backwards-incompatible changes](#) since 0.95, but the upgrade process should be fairly simple and should not require major changes to existing applications.

However, we're also releasing 0.96 now because we have a set of backwards-incompatible changes scheduled for the near future. Once completed, they will involve some code changes for application developers, so we recommend that you stick with Django 0.96 until the next official release; then you'll be able to upgrade in one step instead of needing to make incremental changes to keep up with the development version of Django.

Backwards-incompatible changes

The following changes may require you to update your code when you switch from 0.95 to 0.96:

MySQLdb version requirement

Due to a bug in older versions of the MySQLdb Python module (which Django uses to connect to MySQL databases), Django’s MySQL backend now requires version 1.2.1p2 or higher of MySQLdb, and will raise exceptions if you attempt to use an older version.

If you’re currently unable to upgrade your copy of MySQLdb to meet this requirement, a separate, backwards-compatible backend, called “mysql_old”, has been added to Django. To use this backend, change the `DATABASE_ENGINE` setting in your Django settings file from this:

```
DATABASE_ENGINE = "mysql"
```

to this:

```
DATABASE_ENGINE = "mysql_old"
```

However, we strongly encourage MySQL users to upgrade to a more recent version of MySQLdb as soon as possible. The “mysql_old” backend is provided only to ease this transition, and is considered deprecated; aside from any necessary security fixes, it will not be actively maintained, and it will be removed in a future release of Django.

Also, note that some features, like the new `DATABASE_OPTIONS` setting (see the [databases documentation](#) for details), are only available on the “mysql” backend, and will not be made available for “mysql_old”.

Database constraint names changed

The format of the constraint names Django generates for foreign key references have changed slightly. These names are generally only used when it is not possible to put the reference directly on the affected column, so they are not always visible.

The effect of this change is that running `manage.py reset` and similar commands against an existing database may generate SQL with the new form of constraint name, while the database itself contains constraints named in the old form; this will cause the database server to raise an error message about modifying nonexistent constraints.

If you need to work around this, there are two methods available:

1. Redirect the output of `manage.py` to a file, and edit the generated SQL to use the correct constraint names before executing it.
2. Examine the output of `manage.py sqlall` to see the new-style constraint names, and use that as a guide to rename existing constraints in your database.

Name changes in `manage.py`

A few of the options to `manage.py` have changed with the addition of fixture support:

- There are new `dumpdata` and `loaddata` commands which, as you might expect, will dump and load data to/from the database. These commands can operate against any of Django's supported serialization formats.
- The `sqlinitialdata` command has been renamed to `sqlcustom` to emphasize that `loaddata` should be used for data (and `sqlcustom` for other custom SQL –views, stored procedures, etc.).
- The vestigial `install` command has been removed. Use `syncdb`.

Backslash escaping changed

The Django database API now escapes backslashes given as query parameters. If you have any database API code that matches backslashes, and it was working before (despite the lack of escaping), you'll have to change your code to “unescape” the slashes one level.

For example, this used to work:

```
# Find text containing a single backslash
MyModel.objects.filter(text__contains="\\\\")
```

The above is now incorrect, and should be rewritten as:

```
# Find text containing a single backslash
MyModel.objects.filter(text__contains="\")
```

Removed `ENABLE_PSYCO` setting

The `ENABLE_PSYCO` setting no longer exists. If your settings file includes `ENABLE_PSYCO` it will have no effect; to use `Psyco`, we recommend writing a middleware class to activate it.

What's new in 0.96?

This revision represents over a thousand source commits and over four hundred bug fixes, so we can't possibly catalog all the changes. Here, we describe the most notable changes in this release.

New forms library

`django.newforms` is Django's new form-handling library. It's a replacement for `django.forms`, the old form/manipulator/validation framework. Both APIs are available in 0.96, but over the next two releases we plan to switch completely to the new forms system, and deprecate and remove the old system.

There are three elements to this transition:

- We've copied the current `django.forms` to `django.oldforms`. This allows you to upgrade your code now rather than waiting for the backwards-incompatible change and rushing to fix your code after the fact. Just change your import statements like this:

```
from django import forms # 0.95-style
from django import oldforms as forms # 0.96-style
```

- The next official release of Django will move the current `django.newforms` to `django.forms`. This will be a backwards-incompatible change, and anyone still using the old version of `django.forms` at that time will need to change their import statements as described above.
- The next release after that will completely remove `django.oldforms`.

Although the `newforms` library will continue to evolve, it's ready for use for most common cases. We recommend that anyone new to form handling skip the old forms system and start with the new.

For more information about `django.newforms`, read the [newforms documentation](#).

URLconf improvements

You can now use any callable as the callback in URLconfs (previously, only strings that referred to callables were allowed). This allows a much more natural use of URLconfs. For example, this URLconf:

```
from django.conf.urls.defaults import *

urlpatterns = patterns("", ("^myview/$", "mysite.myapp.views.myview"))
```

can now be rewritten as:

```
from django.conf.urls.defaults import *
from mysite.myapp.views import myview

urlpatterns = patterns("", ("^myview/$", myview))
```

One useful application of this can be seen when using decorators; this change allows you to apply decorators to views in your URLconf. Thus, you can make a generic view require login very easily:

```
from django.conf.urls.defaults import *
from django.contrib.auth.decorators import login_required
from django.views.generic.list_detail import object_list
from mysite.myapp.models import MyModel

info = {
    "queryset": MyModel.objects.all(),
}

urlpatterns = patterns("", ("^myview/$", login_required(object_list), info))
```

Note that both syntaxes (strings and callables) are valid, and will continue to be valid for the foreseeable future.

The test framework

Django now includes a test framework so you can start transmuting fear into boredom (with apologies to Kent Beck). You can write tests based on `doctest` or `unittest` and test your views with a simple test client.

There is also new support for “fixtures”—initial data, stored in any of the supported [serialization formats](#), that will be loaded into your database at the start of your tests. This makes testing with real data much easier.

See [the testing documentation](#) for the full details.

Improvements to the admin interface

A small change, but a very nice one: dedicated views for adding and updating users have been added to the admin interface, so you no longer need to worry about working with hashed passwords in the admin.

Thanks

Since 0.95, a number of people have stepped forward and taken a major new role in Django’s development. We’d like to thank these people for all their hard work:

- Russell Keith-Magee and Malcolm Tredinnick for their major code contributions. This release wouldn’t have been possible without them.
- Our new release manager, James Bennett, for his work in getting out 0.95.1, 0.96, and (hopefully) future release.
- Our ticket managers Chris Beaven (aka SmileyChris), Simon Greenhill, Michael Radziej, and Gary Wilson. They agreed to take on the monumental task of wrangling our tickets into nicely cataloged submission. Figuring out what to work on is now about a million times easier; thanks again, guys.

- Everyone who submitted a bug report, patch or ticket comment. We can't possibly thank everyone by name –over 200 developers submitted patches that went into 0.96 –but everyone who's contributed to Django is listed in [AUTHORS](#).

Django version 0.95 release notes

Welcome to the Django 0.95 release.

This represents a significant advance in Django development since the 0.91 release in January 2006. The details of every change in this release would be too extensive to list in full, but a summary is presented below.

Suitability and API stability

This release is intended to provide a stable reference point for developers wanting to work on production-level applications that use Django.

However, it's not the 1.0 release, and we'll be introducing further changes before 1.0. For a clear look at which areas of the framework will change (and which ones will not change) before 1.0, see the `api-stability.txt` file, which lives in the `docs/` directory of the distribution.

You may have a need to use some of the features that are marked as “subject to API change” in that document, but that's OK with us as long as it's OK with you, and as long as you understand APIs may change in the future.

Fortunately, most of Django's core APIs won't be changing before version 1.0. There likely won't be as big of a change between 0.95 and 1.0 versions as there was between 0.91 and 0.95.

Changes and new features

The major changes in this release (for developers currently using the 0.91 release) are a result of merging the ‘magic-removal’ branch of development. This branch removed a number of constraints in the way Django code had to be written that were a consequence of decisions made in the early days of Django, prior to its open-source release. It's now possible to write more natural, Pythonic code that works as expected, and there's less “black magic” happening behind the scenes.

Aside from that, another main theme of this release is a dramatic increase in usability. We've made countless improvements in error messages, documentation, etc., to improve developers' quality of life.

The new features and changes introduced in 0.95 include:

- Django now uses a more consistent and natural filtering interface for retrieving objects from the database.
- User-defined models, functions and constants now appear in the module namespace they were defined in. (Previously everything was magically transferred to the `django.models.*` namespace.)

- Some optional applications, such as the FlatPage, Sites and Redirects apps, have been decoupled and moved into `django.contrib`. If you don't want to use these applications, you no longer have to install their database tables.
- Django now has support for managing database transactions.
- We've added the ability to write custom authentication and authorization backends for authenticating users against alternate systems, such as LDAP.
- We've made it easier to add custom table-level functions to models, through a new "Manager" API.
- It's now possible to use Django without a database. This simply means that the framework no longer requires you to have a working database set up just to serve dynamic pages. In other words, you can just use URLconfs/views on their own. Previously, the framework required that a database be configured, regardless of whether you actually used it.
- It's now more explicit and natural to override `save()` and `delete()` methods on models, rather than needing to hook into the `pre_save()` and `post_save()` method hooks.
- Individual pieces of the framework now can be configured without requiring the setting of an environment variable. This permits use of, for example, the Django templating system inside other applications.
- More and more parts of the framework have been internationalized, as we've expanded internationalization (i18n) support. The Django codebase, including code and templates, has now been translated, at least in part, into 31 languages. From Arabic to Chinese to Hungarian to Welsh, it is now possible to use Django's admin site in your native language.

The number of changes required to port from 0.91-compatible code to the 0.95 code base are significant in some cases. However, they are, for the most part, reasonably routine and only need to be done once. A list of the necessary changes is described in the [Removing The Magic](#) wiki page. There is also an easy [checklist](#) for reference when undertaking the porting operation.

Problem reports and getting help

Need help resolving a problem with Django? The documentation in the distribution is also available [online](#) at the [Django website](#). The [FAQ](#) document is especially recommended, as it contains a number of issues that come up time and again.

For more personalized help, the [django-users](#) mailing list is a very active list, with more than 2,000 subscribers who can help you solve any sort of Django problem. We recommend you search the archives first, though, because many common questions appear with some regularity, and any particular problem may already have been answered.

Finally, for those who prefer the more immediate feedback offered by IRC, there's a [#django](#) channel on [irc.libera.chat](#) that is regularly populated by Django users and developers from around the world. Friendly people are usually available at any hour of the day –to help, or just to chat.

Thanks for using Django!

The Django Team July 2006

9.2 Security releases

Whenever a security issue is disclosed via [Django's security policies](#), appropriate release notes are now added to all affected release series.

Additionally, [an archive of disclosed security issues](#) is maintained.

9.2.1 Archive of security issues

Django's development team is strongly committed to responsible reporting and disclosure of security-related issues, as outlined in [Django's security policies](#).

As part of that commitment, we maintain the following historical list of issues which have been fixed and disclosed. For each issue, the list below includes the date, a brief description, the [CVE identifier](#) if applicable, a list of affected versions, a link to the full disclosure and links to the appropriate patch(es).

Some important caveats apply to this information:

- Lists of affected versions include only those versions of Django which had stable, security-supported releases at the time of disclosure. This means older versions (whose security support had expired) and versions which were in pre-release (alpha/beta/RC) states at the time of disclosure may have been affected, but are not listed.
- The Django project has on occasion issued security advisories, pointing out potential security problems which can arise from improper configuration or from other issues outside of Django itself. Some of these advisories have received CVEs; when that is the case, they are listed here, but as they have no accompanying patches or releases, only the description, disclosure and CVE will be listed.

Issues under Django's security process

All security issues have been handled under versions of Django's security process. These are listed below.

July 3, 2023 - CVE-2023-36053

Potential regular expression denial of service vulnerability in `EmailValidator/URLValidator`. [Full description](#)

- Django 4.2 ([patch](#))
- Django 4.1 ([patch](#))

- Django 3.2 (patch)

May 3, 2023 - CVE-2023-31047

Potential bypass of validation when uploading multiple files using one form field. [Full description](#)

- Django 4.2 (patch)
- Django 4.1 (patch)
- Django 3.2 (patch)

February 14, 2023 - CVE-2023-24580

Potential denial-of-service vulnerability in file uploads. [Full description](#)

- Django 4.1 (patch)
- Django 4.0 (patch)
- Django 3.2 (patch)

February 1, 2023 - CVE-2023-23969

Potential denial-of-service via Accept-Language headers. [Full description](#)

- Django 4.1 (patch)
- Django 4.0 (patch)
- Django 3.2 (patch)

October 4, 2022 - CVE-2022-41323

Potential denial-of-service vulnerability in internationalized URLs. [Full description](#)

- Django 4.1 (patch)
- Django 4.0 (patch)
- Django 3.2 (patch)

August 3, 2022 - CVE-2022-36359

Potential reflected file download vulnerability in `FileResponse`. [Full description](#)

- Django 4.0 ([patch](#))
- Django 3.2 ([patch](#))

July 4, 2022 - CVE-2022-34265

Potential SQL injection via `Trunc(kind)` and `Extract(lookup_name)` arguments. [Full description](#)

- Django 4.0 ([patch](#))
- Django 3.2 ([patch](#))

April 11, 2022 - CVE-2022-28346

Potential SQL injection in `QuerySet.annotate()`, `aggregate()`, and `extra()`. [Full description](#)

- Django 4.0 ([patch](#))
- Django 3.2 ([patch](#))
- Django 2.2 ([patch](#))

April 11, 2022 - CVE-2022-28347

Potential SQL injection via `QuerySet.explain(**options)` on PostgreSQL. [Full description](#)

- Django 4.0 ([patch](#))
- Django 3.2 ([patch](#))
- Django 2.2 ([patch](#))

February 1, 2022 - CVE-2022-22818

Possible XSS via `{% debug %}` template tag. [Full description](#)

Versions affected

- Django 4.0 (patch)
- Django 3.2 (patch)
- Django 2.2 (patch)

February 1, 2022 - CVE-2022-23833

Denial-of-service possibility in file uploads. [Full description](#)

Versions affected

- Django 4.0 (patch)
- Django 3.2 (patch)
- Django 2.2 (patch)

January 4, 2022 - CVE-2021-45452

Potential directory-traversal via `Storage.save()`. [Full description](#)

Versions affected

- Django 4.0 (patch)
- Django 3.2 (patch)
- Django 2.2 (patch)

January 4, 2022 - CVE-2021-45116

Potential information disclosure in `dictsort` template filter. [Full description](#)

Versions affected

- Django 4.0 ([patch](#))
- Django 3.2 ([patch](#))
- Django 2.2 ([patch](#))

January 4, 2022 - CVE-2021-45115

Denial-of-service possibility in `UserAttributeSimilarityValidator`. [Full description](#)

Versions affected

- Django 4.0 ([patch](#))
- Django 3.2 ([patch](#))
- Django 2.2 ([patch](#))

December 7, 2021 - CVE-2021-44420

Potential bypass of an upstream access control based on URL paths. [Full description](#)

Versions affected

- Django 3.2 ([patch](#))
- Django 3.1 ([patch](#))
- Django 2.2 ([patch](#))

July 1, 2021 - CVE-2021-35042

Potential SQL injection via unsanitized `QuerySet.order_by()` input. [Full description](#)

Versions affected

- Django 3.2 (patch)
- Django 3.1 (patch)

June 2, 2021 - CVE-2021-33203

Potential directory traversal via `admindocs`. [Full description](#)

Versions affected

- Django 3.2 (patch)
- Django 3.1 (patch)
- Django 2.2 (patch)

June 2, 2021 - CVE-2021-33571

Possible indeterminate SSRF, RFI, and LFI attacks since validators accepted leading zeros in IPv4 addresses. [Full description](#)

Versions affected

- Django 3.2 (patch)
- Django 3.1 (patch)
- Django 2.2 (patch)

May 6, 2021 - CVE-2021-32052

Header injection possibility since `URLValidator` accepted newlines in input on Python 3.9.5+. [Full description](#)

Versions affected

- Django 3.2 (patch)
- Django 3.1 (patch)
- Django 2.2 (patch)

May 4, 2021 - CVE-2021-31542

Potential directory-traversal via uploaded files. [Full description](#)

Versions affected

- Django 3.2 (patch)
- Django 3.1 (patch)
- Django 2.2 (patch)

April 6, 2021 - CVE-2021-28658

Potential directory-traversal via uploaded files. [Full description](#)

Versions affected

- Django 3.2 (patch)
- Django 3.1 (patch)
- Django 3.0 (patch)
- Django 2.2 (patch)

February 19, 2021 - CVE-2021-23336

Web cache poisoning via `django.utils.http.limited_parse_qs1()`. [Full description](#)

Versions affected

- Django 3.2 (patch)
- Django 3.1 (patch)
- Django 3.0 (patch)
- Django 2.2 (patch)

February 1, 2021 - CVE-2021-3281

Potential directory-traversal via `archive.extract()`. [Full description](#)

Versions affected

- Django 3.1 (patch)
- Django 3.0 (patch)
- Django 2.2 (patch)

September 1, 2020 - CVE-2020-24584

Permission escalation in intermediate-level directories of the file system cache on Python 3.7+. [Full description](#)

Versions affected

- Django 3.1 (patch)
- Django 3.0 (patch)
- Django 2.2 (patch)

September 1, 2020 - CVE-2020-24583

Incorrect permissions on intermediate-level directories on Python 3.7+. [Full description](#)

Versions affected

- Django 3.1 (patch)
- Django 3.0 (patch)
- Django 2.2 (patch)

June 3, 2020 - CVE-2020-13596

Possible XSS via admin `ForeignKeyRawIdWidget`. [Full description](#)

Versions affected

- Django 3.0 (patch)
- Django 2.2 (patch)

June 3, 2020 - CVE-2020-13254

Potential data leakage via malformed memcached keys. [Full description](#)

Versions affected

- Django 3.0 (patch)
- Django 2.2 (patch)

March 4, 2020 - CVE-2020-9402

Potential SQL injection via `tolerance` parameter in GIS functions and aggregates on Oracle. [Full description](#)

Versions affected

- Django 3.0 (patch)
- Django 2.2 (patch)
- Django 1.11 (patch)

February 3, 2020 - CVE-2020-7471

Potential SQL injection via `StringAgg(delimiter)`. [Full description](#)

Versions affected

- Django 3.0 ([patch](#))
- Django 2.2 ([patch](#))
- Django 1.11 ([patch](#))

December 18, 2019 - CVE-2019-19844

Potential account hijack via password reset form. [Full description](#)

Versions affected

- Django 3.0 ([patch](#))
- Django 2.2 ([patch](#))
- Django 1.11 ([patch](#))

December 2, 2019 - CVE-2019-19118

Privilege escalation in the Django admin. [Full description](#)

Versions affected

- Django 3.0 ([patch](#))
- Django 2.2 ([patch](#))
- Django 2.1 ([patch](#))

August 1, 2019 - CVE-2019-14235

Potential memory exhaustion in `django.utils.encoding.uri_to_iri()`. [Full description](#)

Versions affected

- Django 2.2 (patch)
- Django 2.1 (patch)
- Django 1.11 (patch)

August 1, 2019 - CVE-2019-14234

SQL injection possibility in key and index lookups for `JSONField/HStoreField`. [Full description](#)

Versions affected

- Django 2.2 (patch)
- Django 2.1 (patch)
- Django 1.11 (patch)

August 1, 2019 - CVE-2019-14233

Denial-of-service possibility in `strip_tags()`. [Full description](#)

Versions affected

- Django 2.2 (patch)
- Django 2.1 (patch)
- Django 1.11 (patch)

August 1, 2019 - CVE-2019-14232

Denial-of-service possibility in `django.utils.text.Truncator`. [Full description](#)

Versions affected

- Django 2.2 (patch)
- Django 2.1 (patch)
- Django 1.11 (patch)

July 1, 2019 - CVE-2019-12781

Incorrect HTTP detection with reverse-proxy connecting via HTTPS. [Full description](#)

Versions affected

- Django 2.2 (patch)
- Django 2.1 (patch)
- Django 1.11 (patch)

June 3, 2019 - CVE-2019-12308

XSS via “Current URL” link generated by `AdminURLFieldWidget`. [Full description](#)

Versions affected

- Django 2.2 (patch)
- Django 2.1 (patch)
- Django 1.11 (patch)

June 3, 2019 - CVE-2019-11358

Prototype pollution in bundled jQuery. [Full description](#)

Versions affected

- Django 2.2 (patch)
- Django 2.1 (patch)

February 11, 2019 - CVE-2019-6975

Memory exhaustion in `django.utils.numberformat.format()`. [Full description](#)

Versions affected

- Django 2.1 (patch)
- Django 2.0 (patch and correction)
- Django 1.11 (patch)

January 4, 2019 - CVE-2019-3498

Content spoofing possibility in the default 404 page. [Full description](#)

Versions affected

- Django 2.1 (patch)
- Django 2.0 (patch)
- Django 1.11 (patch)

October 1, 2018 - CVE-2018-16984

Password hash disclosure to “view only” admin users. [Full description](#)

Versions affected

- Django 2.1 (patch)

August 1, 2018 - CVE-2018-14574

Open redirect possibility in `CommonMiddleware`. [Full description](#)

Versions affected

- Django 2.1 (patch)
- Django 2.0 (patch)
- Django 1.11 (patch)

March 6, 2018 - CVE-2018-7537

Denial-of-service possibility in `truncatechars_html` and `truncatewords_html` template filters. [Full description](#)

Versions affected

- Django 2.0 (patch)
- Django 1.11 (patch)
- Django 1.8 (patch)

March 6, 2018 - CVE-2018-7536

Denial-of-service possibility in `urlize` and `urlizetrunc` template filters. [Full description](#)

Versions affected

- Django 2.0 (patch)
- Django 1.11 (patch)
- Django 1.8 (patch)

February 1, 2018 - CVE-2018-6188

Information leakage in `AuthenticationForm`. [Full description](#)

Versions affected

- Django 2.0 ([patch](#))
- Django 1.11 ([patch](#))

September 5, 2017 - CVE-2017-12794

Possible XSS in traceback section of technical 500 debug page. [Full description](#)

Versions affected

- Django 1.11 ([patch](#))
- Django 1.10 ([patch](#))

April 4, 2017 - CVE-2017-7234

Open redirect vulnerability in `django.views.static.serve()`. [Full description](#)

Versions affected

- Django 1.10 ([patch](#))
- Django 1.9 ([patch](#))
- Django 1.8 ([patch](#))

April 4, 2017 - CVE-2017-7233

Open redirect and possible XSS attack via user-supplied numeric redirect URLs. [Full description](#)

Versions affected

- Django 1.10 (patch)
- Django 1.9 (patch)
- Django 1.8 (patch)

November 1, 2016 - CVE-2016-9014

DNS rebinding vulnerability when `DEBUG=True`. [Full description](#)

Versions affected

- Django 1.10 (patch)
- Django 1.9 (patch)
- Django 1.8 (patch)

November 1, 2016 - CVE-2016-9013

User with hardcoded password created when running tests on Oracle. [Full description](#)

Versions affected

- Django 1.10 (patch)
- Django 1.9 (patch)
- Django 1.8 (patch)

September 26, 2016 - CVE-2016-7401

CSRF protection bypass on a site with Google Analytics. [Full description](#)

Versions affected

- Django 1.9 ([patch](#))
- Django 1.8 ([patch](#))

July 18, 2016 - CVE-2016-6186

XSS in admin's add/change related popup. [Full description](#)

Versions affected

- Django 1.9 ([patch](#))
- Django 1.8 ([patch](#))

March 1, 2016 - CVE-2016-2513

User enumeration through timing difference on password hasher work factor upgrade. [Full description](#)

Versions affected

- Django 1.9 ([patch](#))
- Django 1.8 ([patch](#))

March 1, 2016 - CVE-2016-2512

Malicious redirect and possible XSS attack via user-supplied redirect URLs containing basic auth. [Full description](#)

Versions affected

- Django 1.9 ([patch](#))
- Django 1.8 ([patch](#))

February 1, 2016 - CVE-2016-2048

User with “change” but not “add” permission can create objects for `ModelAdmin`’s with `save_as=True`.
[Full description](#)

Versions affected

- Django 1.9 ([patch](#))

November 24, 2015 - CVE-2015-8213

Settings leak possibility in `date` template filter. [Full description](#)

Versions affected

- Django 1.8 ([patch](#))
- Django 1.7 ([patch](#))

August 18, 2015 - CVE-2015-5963 / CVE-2015-5964

Denial-of-service possibility in `logout()` view by filling session store. [Full description](#)

Versions affected

- Django 1.8 ([patch](#))
- Django 1.7 ([patch](#))
- Django 1.4 ([patch](#))

July 8, 2015 - CVE-2015-5145

Denial-of-service possibility in URL validation. [Full description](#)

Versions affected

- Django 1.8 ([patch](#))

July 8, 2015 - CVE-2015-5144

Header injection possibility since validators accept newlines in input. [Full description](#)

Versions affected

- Django 1.8 ([patch](#))
- Django 1.7 ([patch](#))
- Django 1.4 ([patch](#))

July 8, 2015 - CVE-2015-5143

Denial-of-service possibility by filling session store. [Full description](#)

Versions affected

- Django 1.8 ([patch](#))
- Django 1.7 ([patch](#))
- Django 1.4 ([patch](#))

May 20, 2015 - CVE-2015-3982

Fixed session flushing in the `cached_db` backend. [Full description](#)

Versions affected

- Django 1.8 ([patch](#))

March 18, 2015 - CVE-2015-2317

Mitigated possible XSS attack via user-supplied redirect URLs. [Full description](#)

Versions affected

- Django 1.4 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)
- Django 1.8 (patch)

March 18, 2015 - CVE-2015-2316

Denial-of-service possibility with `strip_tags()`. [Full description](#)

Versions affected

- Django 1.6 (patch)
- Django 1.7 (patch)
- Django 1.8 (patch)

March 9, 2015 - CVE-2015-2241

XSS attack via properties in `ModelAdmin.readonly_fields`. [Full description](#)

Versions affected

- Django 1.7 (patch)
- Django 1.8 (patch)

January 13, 2015 - CVE-2015-0222

Database denial-of-service with `ModelMultipleChoiceField`. [Full description](#)

Versions affected

- Django 1.6 (patch)
- Django 1.7 (patch)

January 13, 2015 - CVE-2015-0221

Denial-of-service attack against `django.views.static.serve()`. [Full description](#)

Versions affected

- Django 1.4 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)

January 13, 2015 - CVE-2015-0220

Mitigated possible XSS attack via user-supplied redirect URLs. [Full description](#)

Versions affected

- Django 1.4 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)

January 13, 2015 - CVE-2015-0219

WSGI header spoofing via underscore/dash conflation. [Full description](#)

Versions affected

- Django 1.4 ([patch](#))
- Django 1.6 ([patch](#))
- Django 1.7 ([patch](#))

August 20, 2014 - CVE-2014-0483

Data leakage via querystring manipulation in admin. [Full description](#)

Versions affected

- Django 1.4 ([patch](#))
- Django 1.5 ([patch](#))
- Django 1.6 ([patch](#))
- Django 1.7 ([patch](#))

August 20, 2014 - CVE-2014-0482

RemoteUserMiddleware session hijacking. [Full description](#)

Versions affected

- Django 1.4 ([patch](#))
- Django 1.5 ([patch](#))
- Django 1.6 ([patch](#))
- Django 1.7 ([patch](#))

August 20, 2014 - CVE-2014-0481

File upload denial of service. [Full description](#)

Versions affected

- Django 1.4 (patch)
- Django 1.5 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)

August 20, 2014 - CVE-2014-0480

`reverse()` can generate URLs pointing to other hosts. [Full description](#)

Versions affected

- Django 1.4 (patch)
- Django 1.5 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)

May 18, 2014 - CVE-2014-3730

Malformed URLs from user input incorrectly validated. [Full description](#)

Versions affected

- Django 1.4 (patch)
- Django 1.5 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)

May 18, 2014 - CVE-2014-1418

Caches may be allowed to store and serve private data. [Full description](#)

Versions affected

- Django 1.4 ([patch](#))
- Django 1.5 ([patch](#))
- Django 1.6 ([patch](#))
- Django 1.7 ([patch](#))

April 21, 2014 - CVE-2014-0474

MySQL typecasting causes unexpected query results. [Full description](#)

Versions affected

- Django 1.4 ([patch](#))
- Django 1.5 ([patch](#))
- Django 1.6 ([patch](#))
- Django 1.7 ([patch](#))

April 21, 2014 - CVE-2014-0473

Caching of anonymous pages could reveal CSRF token. [Full description](#)

Versions affected

- Django 1.4 ([patch](#))
- Django 1.5 ([patch](#))
- Django 1.6 ([patch](#))
- Django 1.7 ([patch](#))

April 21, 2014 - CVE-2014-0472

Unexpected code execution using `reverse()`. [Full description](#)

Versions affected

- Django 1.4 (patch)
- Django 1.5 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)

September 14, 2013 - CVE-2013-1443

Denial-of-service via large passwords. [Full description](#)

Versions affected

- Django 1.4 (patch and Python compatibility fix)
- Django 1.5 (patch)

September 10, 2013 - CVE-2013-4315

Directory-traversal via `ssi` template tag. [Full description](#)

Versions affected

- Django 1.4 (patch)
- Django 1.5 (patch)

August 13, 2013 - CVE-2013-6044

Possible XSS via unvalidated URL redirect schemes. [Full description](#)

Versions affected

- Django 1.4 (patch)
- Django 1.5 (patch)

August 13, 2013 - CVE-2013-4249

XSS via admin trusting `URLField` values. [Full description](#)

Versions affected

- Django 1.5 (patch)

February 19, 2013 - CVE-2013-0306

Denial-of-service via formset `max_num` bypass. [Full description](#)

Versions affected

- Django 1.3 (patch)
- Django 1.4 (patch)

February 19, 2013 - CVE-2013-0305

Information leakage via admin history log. [Full description](#)

Versions affected

- Django 1.3 (patch)
- Django 1.4 (patch)

February 19, 2013 - CVE-2013-1664 / CVE-2013-1665

Entity-based attacks against Python XML libraries. [Full description](#)

Versions affected

- Django 1.3 (patch)
- Django 1.4 (patch)

February 19, 2013 - No CVE

Additional hardening of Host header handling. [Full description](#)

Versions affected

- Django 1.3 (patch)
- Django 1.4 (patch)

December 10, 2012 - No CVE 2

Additional hardening of redirect validation. [Full description](#)

Versions affected

- Django 1.3: (patch)
- Django 1.4: (patch)

December 10, 2012 - No CVE 1

Additional hardening of Host header handling. [Full description](#)

Versions affected

- Django 1.3 ([patch](#))
- Django 1.4 ([patch](#))

October 17, 2012 - CVE-2012-4520

Host header poisoning. [Full description](#)

Versions affected

- Django 1.3 ([patch](#))
- Django 1.4 ([patch](#))

July 30, 2012 - CVE-2012-3444

Denial-of-service via large image files. [Full description](#)

Versions affected

- Django 1.3 ([patch](#))
- Django 1.4 ([patch](#))

July 30, 2012 - CVE-2012-3443

Denial-of-service via compressed image files. [Full description](#)

Versions affected

- Django 1.3: ([patch](#))
- Django 1.4: ([patch](#))

July 30, 2012 - CVE-2012-3442

XSS via failure to validate redirect scheme. [Full description](#)

Versions affected

- Django 1.3: [\(patch\)](#)
- Django 1.4: [\(patch\)](#)

September 9, 2011 - CVE-2011-4140

Potential CSRF via Host header. [Full description](#)

Versions affected

This notification was an advisory only, so no patches were issued.

- Django 1.2
- Django 1.3

September 9, 2011 - CVE-2011-4139

Host header cache poisoning. [Full description](#)

Versions affected

- Django 1.2 [\(patch\)](#)
- Django 1.3 [\(patch\)](#)

September 9, 2011 - CVE-2011-4138

Information leakage/arbitrary request issuance via `URLField.verify_exists`. [Full description](#)

Versions affected

- Django 1.2: [\(patch\)](#)
- Django 1.3: [\(patch\)](#)

September 9, 2011 - CVE-2011-4137

Denial-of-service via `URLField.verify_exists`. [Full description](#)

Versions affected

- Django 1.2 [\(patch\)](#)
- Django 1.3 [\(patch\)](#)

September 9, 2011 - CVE-2011-4136

Session manipulation when using memory-cache-backed session. [Full description](#)

Versions affected

- Django 1.2 [\(patch\)](#)
- Django 1.3 [\(patch\)](#)

February 8, 2011 - CVE-2011-0698

Directory-traversal on Windows via incorrect path-separator handling. [Full description](#)

Versions affected

- Django 1.1 [\(patch\)](#)
- Django 1.2 [\(patch\)](#)

February 8, 2011 - CVE-2011-0697

XSS via unsanitized names of uploaded files. [Full description](#)

Versions affected

- Django 1.1 (patch)
- Django 1.2 (patch)

February 8, 2011 - CVE-2011-0696

CSRF via forged HTTP headers. [Full description](#)

Versions affected

- Django 1.1 (patch)
- Django 1.2 (patch)

December 22, 2010 - CVE-2010-4535

Denial-of-service in password-reset mechanism. [Full description](#)

Versions affected

- Django 1.1 (patch)
- Django 1.2 (patch)

December 22, 2010 - CVE-2010-4534

Information leakage in administrative interface. [Full description](#)

Versions affected

- Django 1.1 ([patch](#))
- Django 1.2 ([patch](#))

September 8, 2010 - CVE-2010-3082

XSS via trusting unsafe cookie value. [Full description](#)

Versions affected

- Django 1.2 ([patch](#))

October 9, 2009 - CVE-2009-3965

Denial-of-service via pathological regular expression performance. [Full description](#)

Versions affected

- Django 1.0 ([patch](#))
- Django 1.1 ([patch](#))

July 28, 2009 - CVE-2009-2659

Directory-traversal in development server media handler. [Full description](#)

Versions affected

- Django 0.96 ([patch](#))
- Django 1.0 ([patch](#))

September 2, 2008 - CVE-2008-3909

CSRF via preservation of POST data during admin login. [Full description](#)

Versions affected

- Django 0.91 ([patch](#))
- Django 0.95 ([patch](#))
- Django 0.96 ([patch](#))

May 14, 2008 - CVE-2008-2302

XSS via admin login redirect. [Full description](#)

Versions affected

- Django 0.91 ([patch](#))
- Django 0.95 ([patch](#))
- Django 0.96 ([patch](#))

October 26, 2007 - CVE-2007-5712

Denial-of-service via arbitrarily-large `Accept-Language` header. [Full description](#)

Versions affected

- Django 0.91 ([patch](#))
- Django 0.95 ([patch](#))
- Django 0.96 ([patch](#))

Issues prior to Django's security process

Some security issues were handled before Django had a formalized security process in use. For these, new releases may not have been issued at the time and CVEs may not have been assigned.

January 21, 2007 - CVE-2007-0405

Apparent “caching” of authenticated user. [Full description](#)

Versions affected

- Django 0.95 ([patch](#))

August 16, 2006 - CVE-2007-0404

Filename validation issue in translation framework. [Full description](#)

Versions affected

- Django 0.90 ([patch](#))
- Django 0.91 ([patch](#))
- Django 0.95 ([patch](#)) (released January 21 2007)

DJANGO INTERNALS

Documentation for people hacking on Django itself. This is the place to go if you'd like to help improve Django or learn about how Django is managed.

10.1 Contributing to Django

Django is a community that lives on its volunteers. As it keeps growing, we always need more people to help others. You can contribute in many ways, either on the framework itself or in the wider ecosystem.

10.1.1 Work on the Django framework

The work on Django itself falls into three major areas:

Writing code 

Fix a bug, or add a new feature. You can make a pull request and see your code in the next version of Django!

Start from the [Writing code](#) docs.

Writing documentation 

Django's documentation is one of its key strengths. It's informative and thorough. You can help to improve the documentation and keep it relevant as the framework evolves.

See [Writing documentation](#) for more.

Localizing Django 

Django is translated into over 100 languages - There's even some translation for Klingon?! The i18n team is always looking for translators to help maintain and increase language reach.

See [Localizing Django](#) to help translate Django.

If you think working with Django is fun, wait until you start working on it. Really, ANYONE can do something to help make Django better and greater!

This contributing guide contains everything you need to know to help build the Django web framework. Browse the following sections to find out how:

Advice for new contributors

New contributor and not sure what to do? Want to help but just don't know how to get started? This is the section for you.

Get up and running!

If you are new to contributing to Django, the [Writing your first patch for Django](#) tutorial will give you an introduction to the tools and the workflow.

This page contains more general advice on ways you can contribute to Django, and how to approach that.

If you are looking for a reference on the details of making code contributions, see the [Writing code](#) documentation.

First steps

Start with these steps to discover Django's development process.

- Triage tickets

If an [unreviewed ticket](#) reports a bug, try and reproduce it. If you can reproduce it and it seems valid, make a note that you confirmed the bug and accept the ticket. Make sure the ticket is filed under the correct component area. Consider writing a patch that adds a test for the bug's behavior, even if you don't fix the bug itself. See more at [How can I help with triaging?](#)

- Look for tickets that are accepted and review patches to build familiarity with the codebase and the process

Mark the appropriate flags if a patch needs docs or tests. Look through the changes a patch makes, and keep an eye out for syntax that is incompatible with older but still supported versions of Python. [Run the tests](#) and make sure they pass. Where possible and relevant, try them out on a database other than SQLite. Leave comments and feedback!

- Keep old patches up to date

Oftentimes the codebase will change between a patch being submitted and the time it gets reviewed. Make sure it still applies cleanly and functions as expected. Updating a patch is both useful and important! See more on [Submitting patches](#).

- Write some documentation

Django’s documentation is great but it can always be improved. Did you find a typo? Do you think that something should be clarified? Go ahead and suggest a documentation patch! See also the guide on [Writing documentation](#).

Note: The [reports page](#) contains links to many useful Trac queries, including several that are useful for triaging tickets and reviewing patches as suggested above.

- Sign the Contributor License Agreement

The code that you write belongs to you or your employer. If your contribution is more than one or two lines of code, you need to sign the [CLA](#). See the [Contributor License Agreement FAQ](#) for a more thorough explanation.

Guidelines

As a newcomer on a large project, it’s easy to experience frustration. Here’s some advice to make your work on Django more useful and rewarding.

- Pick a subject area that you care about, that you are familiar with, or that you want to learn about

You don’t already have to be an expert on the area you want to work on; you become an expert through your ongoing contributions to the code.

- Analyze tickets’ context and history

Trac isn’t an absolute; the context is just as important as the words. When reading Trac, you need to take into account who says things, and when they were said. Support for an idea two years ago doesn’t necessarily mean that the idea will still have support. You also need to pay attention to who hasn’t spoken—for example, if an experienced contributor hasn’t been recently involved in a discussion, then a ticket may not have the support required to get into Django.

- Start small

It’s easier to get feedback on a little issue than on a big one. See the [easy pickings](#).

- If you’re going to engage in a big task, make sure that your idea has support first

This means getting someone else to confirm that a bug is real before you fix the issue, and ensuring that there’s consensus on a proposed feature before you go implementing it.

- Be bold! Leave feedback!

Sometimes it can be scary to put your opinion out to the world and say “this ticket is correct” or “this patch needs work”, but it’s the only way the project moves forward. The contributions of the broad Django community ultimately have a much greater impact than that of any one person. We can’t do it without you!

- Err on the side of caution when marking things Ready For Check-in

If you're really not certain if a ticket is ready, don't mark it as such. Leave a comment instead, letting others know your thoughts. If you're mostly certain, but not completely certain, you might also try asking on IRC to see if someone else can confirm your suspicions.

- Wait for feedback, and respond to feedback that you receive

Focus on one or two tickets, see them through from start to finish, and repeat. The shotgun approach of taking on lots of tickets and letting some fall by the wayside ends up doing more harm than good.

- Be rigorous

When we say “[PEP 8](#), and must have docs and tests”, we mean it. If a patch doesn't have docs and tests, there had better be a good reason. Arguments like “I couldn't find any existing tests of this feature” don't carry much weight—while it may be true, that means you have the extra-important job of writing the very first tests for that feature, not that you get a pass from writing tests altogether.

- Be patient

It's not always easy for your ticket or your patch to be reviewed quickly. This isn't personal. There are a lot of tickets and pull requests to get through.

Keeping your patch up to date is important. Review the ticket on Trac to ensure that the Needs tests, Needs documentation, and Patch needs improvement flags are unchecked once you've addressed all review comments.

Remember that Django has an eight-month release cycle, so there's plenty of time for your patch to be reviewed.

Finally, a well-timed reminder can help. See [contributing code FAQ](#) for ideas here.

Reporting bugs and requesting features

Important: Please report security issues only to security@djangoproject.com. This is a private list only open to long-time, highly trusted Django developers, and its archives are not public. For further details, please see [our security policies](#).

Otherwise, before reporting a bug or requesting a new feature on the [ticket tracker](#), consider these points:

- Check that someone hasn't already filed the bug or feature request by [searching](#) or running [custom queries](#) in the ticket tracker.
- Don't use the ticket system to ask support questions. Use the [django-users](#) list or the [#django](#) IRC channel for that.
- Don't reopen issues that have been marked “wontfix” without finding consensus to do so on the [Django Forum](#) or [django-developers](#) list.

- Don't use the ticket tracker for lengthy discussions, because they're likely to get lost. If a particular ticket is controversial, please move the discussion to the [Django Forum](#) or [django-developers](#) list.

Reporting bugs

Well-written bug reports are incredibly helpful. However, there's a certain amount of overhead involved in working with any bug tracking system so your help in keeping our ticket tracker as useful as possible is appreciated. In particular:

- Do read the [FAQ](#) to see if your issue might be a well-known question.
- Do ask on [django-users](#) or [#django](#) first if you're not sure if what you're seeing is a bug.
- Do write complete, reproducible, specific bug reports. You must include a clear, concise description of the problem, and a set of instructions for replicating it. Add as much debug information as you can: code snippets, test cases, exception backtraces, screenshots, etc. A nice small test case is the best way to report a bug, as it gives us a helpful way to confirm the bug quickly.
- Don't post to [django-developers](#) only to announce that you have filed a bug report. All the tickets are mailed to another list, [django-updates](#), which is tracked by developers and interested community members; we see them as they are filed.

To understand the lifecycle of your ticket once you have created it, refer to [Triaging tickets](#).

Reporting user interface bugs and features

If your bug or feature request touches on anything visual in nature, there are a few additional guidelines to follow:

- Include screenshots in your ticket which are the visual equivalent of a minimal test case. Show off the issue, not the crazy customizations you've made to your browser.
- If the issue is difficult to show off using a still image, consider capturing a brief screencast. If your software permits it, capture only the relevant area of the screen.
- If you're offering a patch that changes the look or behavior of Django's UI, you must attach before and after screenshots/screencasts. Tickets lacking these are difficult for triagers to assess quickly.
- Screenshots don't absolve you of other good reporting practices. Make sure to include URLs, code snippets, and step-by-step instructions on how to reproduce the behavior visible in the screenshots.
- Make sure to set the UI/UX flag on the ticket so interested parties can find your ticket.

Requesting features

We’re always trying to make Django better, and your feature requests are a key part of that. Here are some tips on how to make a request most effectively:

- Make sure the feature actually requires changes in Django’s core. If your idea can be developed as an independent application or module—for instance, you want to support another database engine—we’ll probably suggest that you develop it independently. Then, if your project gathers sufficient community support, we may consider it for inclusion in Django.
- First request the feature on the [Django Forum](#) or [django-developers](#) list, not in the ticket tracker. It’ll get read more closely if it’s on the mailing list. This is even more important for large-scale feature requests. We like to discuss any big changes to Django’s core before actually working on them.
- Describe clearly and concisely what the missing feature is and how you’d like to see it implemented. Include example code (non-functional is OK) if possible.
- Explain why you’d like the feature. Explaining a minimal use case will help others understand where it fits in, and if there are already other ways of achieving the same thing.

If there’s a consensus agreement on the feature, then it’s appropriate to create a ticket. Include a link to the discussion in the ticket description.

As with most open-source projects, code talks. If you are willing to write the code for the feature yourself or, even better, if you’ve already written it, it’s much more likely to be accepted. Fork Django on GitHub, create a feature branch, and show us your work!

See also: [Documenting new features](#).

How we make decisions

Whenever possible, we strive for a rough consensus. To that end, we’ll often have informal votes on [django-developers](#) or the Django Forum about a feature. In these votes we follow the voting style invented by Apache and used on Python itself, where votes are given as +1, +0, -0, or -1. Roughly translated, these votes mean:

- +1: “I love the idea and I’m strongly committed to it.”
- +0: “Sounds OK to me.”
- -0: “I’m not thrilled, but I won’t stand in the way.”
- -1: “I strongly disagree and would be very unhappy to see the idea turn into reality.”

Although these votes are informal, they’ll be taken very seriously. After a suitable voting period, if an obvious consensus arises we’ll follow the votes.

However, consensus is not always possible. If consensus cannot be reached, or if the discussion toward a consensus fizzles out without a concrete decision, the decision may be deferred to the [steering council](#).

Internally, the steering council will use the same voting mechanism. A proposition will be considered carried if:

- There are at least three “+1” votes from members of the steering council.
- There is no “-1” vote from any member of the steering council.

Votes should be submitted within a week.

Since this process allows any steering council member to veto a proposal, a “-1” vote should be accompanied by an explanation of what it would take to convert that “-1” into at least a “+0” .

Votes on technical matters should be announced and held in public on the [django-developers](#) mailing list or on the [Django Forum](#).

Triaging tickets

Django uses [Trac](#) for managing the work on the code base. Trac is a community-tended garden of the bugs people have found and the features people would like to see added. As in any garden, sometimes there are weeds to be pulled and sometimes there are flowers and vegetables that need picking. We need your help to sort out one from the other, and in the end, we all benefit together.

Like all gardens, we can aspire to perfection, but in reality there’ s no such thing. Even in the most pristine garden there are still snails and insects. In a community garden there are also helpful people who –with the best of intentions –fertilize the weeds and poison the roses. It’ s the job of the community as a whole to self-manage, keep the problems to a minimum, and educate those coming into the community so that they can become valuable contributing members.

Similarly, while we aim for Trac to be a perfect representation of the state of Django’ s progress, we acknowledge that this will not happen. By distributing the load of Trac maintenance to the community, we accept that there will be mistakes. Trac is “mostly accurate” , and we give allowances for the fact that sometimes it will be wrong. That’ s okay. We’ re perfectionists with deadlines.

We rely on the community to keep participating, keep tickets as accurate as possible, and raise issues for discussion on our mailing lists when there is confusion or disagreement.

Django is a community project, and every contribution helps. We can’ t do this without you!

Triage workflow

Unfortunately, not all bug reports and feature requests in the ticket tracker provide all the [required details](#). A number of tickets have patches, but those patches don’ t meet all the requirements of a [good patch](#).

One way to help out is to triage tickets that have been created by other users.

Most of the workflow is based around the concept of a ticket’ s [triage stages](#). Each stage describes where in its lifetime a given ticket is at any time. Along with a handful of flags, this attribute easily tells us what and who each ticket is waiting on.

Since a picture is worth a thousand words, let's start there:

We've got two roles in this diagram:

- **Mergers:** people with commit access who are responsible for making the final decision to merge a patch.
- **Ticket triagers:** anyone in the Django community who chooses to become involved in Django's development process. Our Trac installation is intentionally left open to the public, and anyone can triage tickets. Django is a community project, and we encourage [triage by the community](#).

By way of example, here we see the lifecycle of an average ticket:

- Alice creates a ticket and sends an incomplete pull request (no tests, incorrect implementation).
- Bob reviews the pull request, marks the ticket as "Accepted", "needs tests", and "patch needs improvement", and leaves a comment telling Alice how the patch could be improved.
- Alice updates the pull request, adding tests (but not changing the implementation). She removes the two flags.
- Charlie reviews the pull request and resets the "patch needs improvement" flag with another comment about improving the implementation.

- Alice updates the pull request, fixing the implementation. She removes the “patch needs improvement” flag.
- Daisy reviews the pull request and marks the ticket as “Ready for checkin” .
- Jacob, a [merger](#), reviews the pull request and merges it.

Some tickets require much less feedback than this, but then again some tickets require much much more.

Triage stages

Below we describe in more detail the various stages that a ticket may flow through during its lifetime.

Unreviewed

The ticket has not been reviewed by anyone who felt qualified to make a judgment about whether the ticket contained a valid issue, a viable feature, or ought to be closed for any of the various reasons.

Accepted

The big gray area! The absolute meaning of “accepted” is that the issue described in the ticket is valid and is in some stage of being worked on. Beyond that there are several considerations:

- Accepted + No Flags

The ticket is valid, but no one has submitted a patch for it yet. Often this means you could safely start writing a patch for it. This is generally more true for the case of accepted bugs than accepted features. A ticket for a bug that has been accepted means that the issue has been verified by at least one triager as a legitimate bug - and should probably be fixed if possible. An accepted new feature may only mean that one triager thought the feature would be good to have, but this alone does not represent a consensus view or imply with any certainty that a patch will be accepted for that feature. Seek more feedback before writing an extensive patch if you are in doubt.

- Accepted + Has Patch

The ticket is waiting for people to review the supplied patch. This means downloading the patch and trying it out, verifying that it contains tests and docs, running the test suite with the included patch, and leaving feedback on the ticket.

- Accepted + Has Patch + Needs ...

This means the ticket has been reviewed, and has been found to need further work. “Needs tests” and “Needs documentation” are self-explanatory. “Patch needs improvement” will generally be accompanied by a comment on the ticket explaining what is needed to improve the code.

Ready For Checkin

The ticket was reviewed by any member of the community other than the person who supplied the patch and found to meet all the requirements for a commit-ready patch. A [merger](#) now needs to give the patch a final review prior to being committed.

There are a lot of pull requests. It can take a while for your patch to get reviewed. See the [contributing code FAQ](#) for some ideas here.

Someday/Maybe

This stage isn't shown on the diagram. It's used sparingly to keep track of high-level ideas or long-term feature requests.

These tickets are uncommon and overall less useful since they don't describe concrete actionable issues. They are enhancement requests that we might consider adding someday to the framework if an excellent patch is submitted. They are not a high priority.

Other triage attributes

A number of flags, appearing as checkboxes in Trac, can be set on a ticket:

Has patch

This means the ticket has an associated [patch](#). These will be reviewed to see if the patch is “good” .

The following three fields (Needs documentation, Needs tests, Patch needs improvement) apply only if a patch has been supplied.

Needs documentation

This flag is used for tickets with patches that need associated documentation. Complete documentation of features is a prerequisite before we can check them into the codebase.

Needs tests

This flags the patch as needing associated unit tests. Again, this is a required part of a valid patch.

Patch needs improvement

This flag means that although the ticket has a patch, it's not quite ready for checkin. This could mean the patch no longer applies cleanly, there is a flaw in the implementation, or that the code doesn't meet our standards.

Easy pickings

Tickets that would require small, easy, patches.

Type

Tickets should be categorized by type between:

- New Feature
For adding something new.
- Bug
For when an existing thing is broken or not behaving as expected.
- Cleanup/optimization
For when nothing is broken but something could be made cleaner, better, faster, stronger.

Component

Tickets should be classified into components indicating which area of the Django codebase they belong to. This makes tickets better organized and easier to find.

Severity

The severity attribute is used to identify blockers, that is, issues that should get fixed before releasing the next version of Django. Typically those issues are bugs causing regressions from earlier versions or potentially causing severe data losses. This attribute is quite rarely used and the vast majority of tickets have a severity of "Normal" .

Version

It is possible to use the version attribute to indicate in which version the reported bug was identified.

UI/UX

This flag is used for tickets that relate to User Interface and User Experiences questions. For example, this flag would be appropriate for user-facing features in forms or the admin interface.

Cc

You may add your username or email address to this field to be notified when new contributions are made to the ticket.

Keywords

With this field you may label a ticket with multiple keywords. This can be useful, for example, to group several tickets on the same theme. Keywords can either be comma or space separated. Keyword search finds the keyword string anywhere in the keywords. For example, clicking on a ticket with the keyword “form” will yield similar tickets tagged with keywords containing strings such as “formset” , “modelformset” , and “ManagementForm” .

Closing Tickets

When a ticket has completed its useful lifecycle, it’s time for it to be closed. Closing a ticket is a big responsibility, though. You have to be sure that the issue is really resolved, and you need to keep in mind that the reporter of the ticket may not be happy to have their ticket closed (unless it’s fixed!). If you’re not certain about closing a ticket, leave a comment with your thoughts instead.

If you do close a ticket, you should always make sure of the following:

- Be certain that the issue is resolved.
- Leave a comment explaining the decision to close the ticket.
- If there is a way they can improve the ticket to reopen it, let them know.
- If the ticket is a duplicate, reference the original ticket. Also cross-reference the closed ticket by leaving a comment in the original one –this allows to access more related information about the reported bug or requested feature.
- Be polite. No one likes having their ticket closed. It can be frustrating or even discouraging. The best way to avoid turning people off from contributing to Django is to be polite and friendly and to offer suggestions for how they could improve this ticket and other tickets in the future.

A ticket can be resolved in a number of ways:

- **fixed**
Used once a patch has been rolled into Django and the issue is fixed.
- **invalid**
Used if the ticket is found to be incorrect. This means that the issue in the ticket is actually the result of a user error, or describes a problem with something other than Django, or isn't a bug report or feature request at all (for example, some new users submit support queries as tickets).
- **wontfix**
Used when someone decides that the request isn't appropriate for consideration in Django. Sometimes a ticket is closed as "wontfix" with a request for the reporter to start a discussion on the [Django Forum](#) or [django-developers](#) mailing list if they feel differently from the rationale provided by the person who closed the ticket. Other times, a discussion precedes the decision to close a ticket. Always use the forum or mailing list to get a consensus before reopening tickets closed as "wontfix" .
- **duplicate**
Used when another ticket covers the same issue. By closing duplicate tickets, we keep all the discussion in one place, which helps everyone.
- **worksforme**
Used when the ticket doesn't contain enough detail to replicate the original bug.
- **needsinfo**
Used when the ticket does not contain enough information to replicate the reported issue but is potentially still valid. The ticket should be reopened when more information is supplied.

If you believe that the ticket was closed in error –because you're still having the issue, or it's popped up somewhere else, or the triagers have made a mistake –please reopen the ticket and provide further information. Again, please do not reopen tickets that have been marked as "wontfix" and bring the issue to the [Django Forum](#) or [django-developers](#) instead.

How can I help with triaging?

The triage process is primarily driven by community members. Really, ANYONE can help.

To get involved, start by [creating an account on Trac](#). If you have an account but have forgotten your password, you can reset it using the [password reset](#) page.

Then, you can help out by:

- Closing "Unreviewed" tickets as "invalid" , "worksforme" , or "duplicate" , or "wontfix" .
- Closing "Unreviewed" tickets as "needsinfo" when the description is too sparse to be actionable, or when they're feature requests requiring a discussion on the [Django Forum](#) or [django-developers](#).

- Correcting the “Needs tests” , “Needs documentation” , or “Has patch” flags for tickets where they are incorrectly set.
- Setting the “[Easy pickings](#)” flag for tickets that are small and relatively straightforward.
- Set the type of tickets that are still uncategorized.
- Checking that old tickets are still valid. If a ticket hasn’ t seen any activity in a long time, it’ s possible that the problem has been fixed but the ticket hasn’ t yet been closed.
- Identifying trends and themes in the tickets. If there are a lot of bug reports about a particular part of Django, it may indicate we should consider refactoring that part of the code. If a trend is emerging, you should raise it for discussion (referencing the relevant tickets) on the [Django Forum](#) or [django-developers](#).
- Verify if patches submitted by other users are correct. If they are correct and also contain appropriate documentation and tests then move them to the “Ready for Checkin” stage. If they are not correct then leave a comment to explain why and set the corresponding flags (“Patch needs improvement” , “Needs tests” etc.).

Note: The [Reports](#) page contains links to many useful Trac queries, including several that are useful for triaging tickets and reviewing patches as suggested above.

You can also find more [Advice for new contributors](#).

However, we do ask the following of all general community members working in the ticket database:

- Please don’ t promote your own tickets to “Ready for checkin” . You may mark other people’ s tickets that you’ ve reviewed as “Ready for checkin” , but you should get at minimum one other community member to review a patch that you submit.
- Please don’ t reverse a decision without posting a message to the [Django Forum](#) or [django-developers](#) to find consensus.
- If you’ re unsure if you should be making a change, don’ t make the change but instead leave a comment with your concerns on the ticket, or post a message to the [Django Forum](#) or [django-developers](#). It’ s okay to be unsure, but your input is still valuable.

Bisecting a regression

A regression is a bug that’ s present in some newer version of Django but not in an older one. An extremely helpful piece of information is the commit that introduced the regression. Knowing the commit that caused the change in behavior helps identify if the change was intentional or if it was an inadvertent side-effect. Here’ s how you can determine this.

Begin by writing a regression test for Django’ s test suite for the issue. For example, we’ ll pretend we’ re debugging a regression in migrations. After you’ ve written the test and confirmed that it fails on the latest

main branch, put it in a separate file that you can run standalone. For our example, we’ ll pretend we created `tests/migrations/test_regression.py`, which can be run with:

```
$ ./runtests.py migrations.test_regression
```

Next, we mark the current point in history as being “bad” since the test fails:

```
$ git bisect bad
You need to start by "git bisect start"
Do you want me to do it for you [Y/n]? y
```

Now, we need to find a point in git history before the regression was introduced (i.e. a point where the test passes). Use something like `git checkout HEAD~100` to check out an earlier revision (100 commits earlier, in this case). Check if the test fails. If so, mark that point as “bad” (`git bisect bad`), then check out an earlier revision and recheck. Once you find a revision where your test passes, mark it as “good” :

```
$ git bisect good
Bisecting: X revisions left to test after this (roughly Y steps)
...
```

Now we’ re ready for the fun part: using `git bisect run` to automate the rest of the process:

```
$ git bisect run tests/runtests.py migrations.test_regression
```

You should see `git bisect` use a binary search to automatically checkout revisions between the good and bad commits until it finds the first “bad” commit where the test fails.

Now, report your results on the Trac ticket, and please include the regression test as an attachment. When someone writes a fix for the bug, they’ ll already have your test as a starting point.

Writing code

So you’ d like to write some code to improve Django? Awesome! There are several ways you can help Django’ s development:

- [Report bugs](#) in our [ticket tracker](#).
- Join the [django-developers](#) mailing list and share your ideas for how to improve Django. We’ re always open to suggestions. You can also interact on the [Django forum](#) and the [#django-dev IRC channel](#).
- [Submit patches](#) for new and/or fixed behavior. If you’ re looking for a way to get started contributing to Django read the [Writing your first patch for Django](#) tutorial and have a look at the [easy pickings](#) tickets. The [Patch review checklist](#) will also be helpful.
- [Improve the documentation](#) or [write unit tests](#).
- [Triage tickets](#) and [review patches](#) created by other users.

- Read the [Advice for new contributors](#) to help you get orientated in the development process.

Browse the following sections to find out how to give your code patches the best chances to be included in Django core:

Coding style

Please follow these coding standards when writing code for inclusion in Django.

Pre-commit checks

`pre-commit` is a framework for managing pre-commit hooks. These hooks help to identify simple issues before committing code for review. By checking for these issues before code review it allows the reviewer to focus on the change itself, and it can also help to reduce the number of CI runs.

To use the tool, first install `pre-commit` and then the git hooks:

```
$ python -m pip install pre-commit
$ pre-commit install
```

On the first commit `pre-commit` will install the hooks, these are installed in their own environments and will take a short while to install on the first run. Subsequent checks will be significantly faster. If an error is found an appropriate error message will be displayed. If the error was with `black` or `isort` then the tool will go ahead and fix them for you. Review the changes and re-stage for commit if you are happy with them.

Python style

- All files should be formatted using the `black` auto-formatter. This will be run by `pre-commit` if that is configured.
- The project repository includes an `.editorconfig` file. We recommend using a text editor with `EditorConfig` support to avoid indentation and whitespace issues. The Python files use 4 spaces for indentation and the HTML files use 2 spaces.
- Unless otherwise specified, follow [PEP 8](#).

Use `flake8` to check for problems in this area. Note that our `setup.cfg` file contains some excluded files (deprecated modules we don't care about cleaning up and some third-party code that Django vendors) as well as some excluded errors that we don't consider as gross violations. Remember that [PEP 8](#) is only a guide, so respect the style of the surrounding code as a primary goal.

An exception to [PEP 8](#) is our rules on line lengths. Don't limit lines of code to 79 characters if it means the code looks significantly uglier or is harder to read. We allow up to 88 characters as this is the line length used by `black`. This check is included when you run `flake8`. Documentation, comments, and docstrings should be wrapped at 79 characters, even though [PEP 8](#) suggests 72.

- String variable interpolation may use %-formatting, f-strings, or `str.format()` as appropriate, with the goal of maximizing code readability.

Final judgments of readability are left to the Merger’s discretion. As a guide, f-strings should use only plain variable and property access, with prior local variable assignment for more complex cases:

```
# Allowed
f"hello {user}"
f"hello {user.name}"
f"hello {self.user.name}"

# Disallowed
f"hello {get_user()}"
f"you are {user.age * 365.25} days old"

# Allowed with local variable assignment
user = get_user()
f"hello {user}"
user_days_old = user.age * 365.25
f"you are {user_days_old} days old"
```

f-strings should not be used for any string that may require translation, including error and logging messages. In general `format()` is more verbose, so the other formatting methods are preferred.

Don’t waste time doing unrelated refactoring of existing code to adjust the formatting method.

- Avoid use of “we” in comments, e.g. “Loop over” rather than “We loop over” .
- Use underscores, not camelCase, for variable, function and method names (i.e. `poll.get_unique_voters()`, not `poll.getUniqueVoters()`).
- Use `InitialCaps` for class names (or for factory functions that return classes).
- In docstrings, follow the style of existing docstrings and [PEP 257](#).
- In tests, use `assertRaisesMessage()` and `assertWarnsMessage()` instead of `assertRaises()` and `assertWarns()` so you can check the exception or warning message. Use `assertRaisesRegex()` and `assertWarnsRegex()` only if you need regular expression matching.

Use `assertIs(..., True/False)` for testing boolean values, rather than `assertTrue()` and `assertFalse()`, so you can check the actual boolean value, not the truthiness of the expression.

- In test docstrings, state the expected behavior that each test demonstrates. Don’t include preambles such as “Tests that” or “Ensures that” .

Reserve ticket references for obscure issues where the ticket has additional details that can’t be easily described in docstrings or comments. Include the ticket number at the end of a sentence like this:

```
def test_foo():
    """
    A test docstring looks like this (#123456).
    """
    ...
```

Imports

- Use `isort` to automate import sorting using the guidelines below.

Quick start:

```
$ python -m pip install "isort >= 5.1.0"
$ isort .
```

This runs `isort` recursively from your current directory, modifying any files that don't conform to the guidelines. If you need to have imports out of order (to avoid a circular import, for example) use a comment like this:

```
import module # isort:skip
```

- Put imports in these groups: future, standard library, third-party libraries, other Django components, local Django component, try/excepts. Sort lines in each group alphabetically by the full module name. Place all `import module` statements before `from module import objects` in each section. Use absolute imports for other Django components and relative imports for local components.
- On each line, alphabetize the items with the upper case items grouped before the lowercase items.
- Break long lines using parentheses and indent continuation lines by 4 spaces. Include a trailing comma after the last import and put the closing parenthesis on its own line.

Use a single blank line between the last import and any module level code, and use two blank lines above the first function or class.

For example (comments are for explanatory purposes only):

Listing 1: `django/contrib/admin/example.py`

```
# future
from __future__ import unicode_literals

# standard library
import json
from itertools import chain
```

(continues on next page)

(continued from previous page)

```
# third-party
import bcrypt

# Django
from django.http import Http404
from django.http.response import (
    Http404,
    HttpResponse,
    HttpResponseNotAllowed,
    StreamingHttpResponse,
    cookie,
)

# local Django
from .models import LogEntry

# try/except
try:
    import yaml
except ImportError:
    yaml = None

CONSTANT = "foo"

class Example:
    ...
```

- Use convenience imports whenever available. For example, do this

```
from django.views import View
```

instead of:

```
from django.views.generic.base import View
```

Template style

- In Django template code, put one (and only one) space between the curly brackets and the tag contents.

Do this:

```
{{ foo }}
```

Don't do this:

```
{{foo}}
```

View style

- In Django views, the first parameter in a view function should be called `request`.

Do this:

```
def my_view(request, foo):  
    ...
```

Don't do this:

```
def my_view(req, foo):  
    ...
```

Model style

- Field names should be all lowercase, using underscores instead of camelCase.

Do this:

```
class Person(models.Model):  
    first_name = models.CharField(max_length=20)  
    last_name = models.CharField(max_length=40)
```

Don't do this:

```
class Person(models.Model):  
    FirstName = models.CharField(max_length=20)  
    LastName = models.CharField(max_length=40)
```

- The class `Meta` should appear after the fields are defined, with a single blank line separating the fields and the class definition.

Do this:

```
class Person(models.Model):
    first_name = models.CharField(max_length=20)
    last_name = models.CharField(max_length=40)

    class Meta:
        verbose_name_plural = "people"
```

Don't do this:

```
class Person(models.Model):
    class Meta:
        verbose_name_plural = "people"

    first_name = models.CharField(max_length=20)
    last_name = models.CharField(max_length=40)
```

- The order of model inner classes and standard methods should be as follows (noting that these are not all required):
 - All database fields
 - Custom manager attributes
 - class Meta
 - def __str__()
 - def save()
 - def get_absolute_url()
 - Any custom methods
- If choices is defined for a given model field, define each choice as a list of tuples, with an all-uppercase name as a class attribute on the model. Example:

```
class MyModel(models.Model):
    DIRECTION_UP = "U"
    DIRECTION_DOWN = "D"
    DIRECTION_CHOICES = [
        (DIRECTION_UP, "Up"),
        (DIRECTION_DOWN, "Down"),
    ]
```

Use of `django.conf.settings`

Modules should not in general use settings stored in `django.conf.settings` at the top level (i.e. evaluated when the module is imported). The explanation for this is as follows:

Manual configuration of settings (i.e. not relying on the `DJANGO_SETTINGS_MODULE` environment variable) is allowed and possible as follows:

```
from django.conf import settings

settings.configure({}, SOME_SETTING="foo")
```

However, if any setting is accessed before the `settings.configure` line, this will not work. (Internally, `settings` is a `LazyObject` which configures itself automatically when the settings are accessed if it has not already been configured).

So, if there is a module containing some code as follows:

```
from django.conf import settings
from django.urls import get_callable

default_foo_view = get_callable(settings.FOO_VIEW)
```

...then importing this module will cause the settings object to be configured. That means that the ability for third parties to import the module at the top level is incompatible with the ability to configure the settings object manually, or makes it very difficult in some circumstances.

Instead of the above code, a level of laziness or indirection must be used, such as `django.utils.functional.LazyObject`, `django.utils.functional.lazy()` or `lambda`.

Miscellaneous

- Mark all strings for internationalization; see the [i18n documentation](#) for details.
- Remove `import` statements that are no longer used when you change code. `flake8` will identify these imports for you. If an unused import needs to remain for backwards-compatibility, mark the end of with `# NOQA` to silence the `flake8` warning.
- Systematically remove all trailing whitespaces from your code as those add unnecessary bytes, add visual clutter to the patches and can also occasionally cause unnecessary merge conflicts. Some IDE's can be configured to automatically remove them and most VCS tools can be set to highlight them in diff outputs.
- Please don't put your name in the code you contribute. Our policy is to keep contributors' names in the `AUTHORS` file distributed with Django –not scattered throughout the codebase itself. Feel free to include a change to the `AUTHORS` file in your patch if you make more than a single trivial change.

JavaScript style

For details about the JavaScript code style used by Django, see [JavaScript](#).

Unit tests

Django comes with a test suite of its own, in the `tests` directory of the code base. It's our policy to make sure all tests pass at all times.

We appreciate any and all contributions to the test suite!

The Django tests all use the testing infrastructure that ships with Django for testing applications. See [Writing and running tests](#) for an explanation of how to write new tests.

Running the unit tests

Quickstart

First, [fork Django on GitHub](#).

Second, create and activate a virtual environment. If you're not familiar with how to do that, read our [contributing tutorial](#).

Next, clone your fork, install some requirements, and run the tests:

```
$ git clone https://github.com/YourGitHubName/django.git django-repo
$ cd django-repo/tests
$ python -m pip install -e ..
$ python -m pip install -r requirements/py3.txt
$ ./runtests.py
```

Installing the requirements will likely require some operating system packages that your computer doesn't have installed. You can usually figure out which package to install by doing a web search for the last line or so of the error message. Try adding your operating system to the search query if needed.

If you have trouble installing the requirements, you can skip that step. See [Running all the tests](#) for details on installing the optional test dependencies. If you don't have an optional dependency installed, the tests that require it will be skipped.

Running the tests requires a Django settings module that defines the databases to use. To help you get started, Django provides and uses a sample settings module that uses the SQLite database. See [Using another settings module](#) to learn how to use a different settings module to run the tests with a different database.

Having problems? See [Troubleshooting](#) for some common issues.

Running tests using tox

`Tox` is a tool for running tests in different virtual environments. Django includes a basic `tox.ini` that automates some checks that our build server performs on pull requests. To run the unit tests and other checks (such as [import sorting](#), the [documentation spelling checker](#), and [code formatting](#)), install and run the `tox` command from any place in the Django source tree:

```
$ python -m pip install tox
$ tox
```

By default, `tox` runs the test suite with the bundled test settings file for SQLite, `black`, `blacken-docs`, `flake8`, `isort`, and the documentation spelling checker. In addition to the system dependencies noted elsewhere in this documentation, the command `python3` must be on your path and linked to the appropriate version of Python. A list of default environments can be seen as follows:

```
$ tox -l
py3
black
blacken-docs
flake8>=3.7.0
docs
isort>=5.1.0
```

Testing other Python versions and database backends

In addition to the default environments, `tox` supports running unit tests for other versions of Python and other database backends. Since Django's test suite doesn't bundle a settings file for database backends other than SQLite, however, you must [create and provide your own test settings](#). For example, to run the tests on Python 3.9 using PostgreSQL:

```
$ tox -e py39-postgres -- --settings=my_postgres_settings
```

This command sets up a Python 3.9 virtual environment, installs Django's test suite dependencies (including those for PostgreSQL), and calls `runtests.py` with the supplied arguments (in this case, `--settings=my_postgres_settings`).

The remainder of this documentation shows commands for running tests without `tox`, however, any option passed to `runtests.py` can also be passed to `tox` by prefixing the argument list with `--`, as above.

`Tox` also respects the `DJANGO_SETTINGS_MODULE` environment variable, if set. For example, the following is equivalent to the command above:

```
$ DJANGO_SETTINGS_MODULE=my_postgres_settings tox -e py39-postgres
```

Windows users should use:

```
...\> set DJANGO_SETTINGS_MODULE=my_postgres_settings
...\> tox -e py39-postgres
```

Running the JavaScript tests

Django includes a set of [JavaScript unit tests](#) for functions in certain contrib apps. The JavaScript tests aren't run by default using `tox` because they require `Node.js` to be installed and aren't necessary for the majority of patches. To run the JavaScript tests using `tox`:

```
$ tox -e javascript
```

This command runs `npm install` to ensure test requirements are up to date and then runs `npm test`.

Running tests using `django-docker-box`

[django-docker-box](#) allows you to run the Django's test suite across all supported databases and python versions. See the [django-docker-box](#) project page for installation and usage instructions.

Using another settings module

The included settings module (`tests/test_sqlite.py`) allows you to run the test suite using SQLite. If you want to run the tests using a different database, you'll need to define your own settings file. Some tests, such as those for `contrib.postgres`, are specific to a particular database backend and will be skipped if run with a different backend. Some tests are skipped or expected failures on a particular database backend (see `DatabaseFeatures.django_test_skips` and `DatabaseFeatures.django_test_expected_failures` on each backend).

To run the tests with different settings, ensure that the module is on your `PYTHONPATH` and pass the module with `--settings`.

The [DATABASES](#) setting in any test settings module needs to define two databases:

- A `default` database. This database should use the backend that you want to use for primary testing.
- A database with the alias `other`. The `other` database is used to test that queries can be directed to different databases. This database should use the same backend as the `default`, and it must have a different name.

If you're using a backend that isn't SQLite, you will need to provide other details for each database:

- The [USER](#) option needs to specify an existing user account for the database. That user needs permission to execute `CREATE DATABASE` so that the test database can be created.

- The `PASSWORD` option needs to provide the password for the `USER` that has been specified.

Test databases get their names by prepending `test_` to the value of the `NAME` settings for the databases defined in `DATABASES`. These test databases are deleted when the tests are finished.

You will also need to ensure that your database uses UTF-8 as the default character set. If your database server doesn't use UTF-8 as a default charset, you will need to include a value for `CHARSET` in the test settings dictionary for the applicable database.

Running only some of the tests

Django's entire test suite takes a while to run, and running every single test could be redundant if, say, you just added a test to Django that you want to run quickly without running everything else. You can run a subset of the unit tests by appending the names of the test modules to `runtests.py` on the command line.

For example, if you'd like to run tests only for generic relations and internationalization, type:

```
$ ./runtests.py --settings=path.to.settings generic_relations i18n
```

How do you find out the names of individual tests? Look in `tests/` —each directory name there is the name of a test.

If you want to run only a particular class of tests, you can specify a list of paths to individual test classes. For example, to run the `TranslationTests` of the `i18n` module, type:

```
$ ./runtests.py --settings=path.to.settings i18n.tests.TranslationTests
```

Going beyond that, you can specify an individual test method like this:

```
$ ./runtests.py --settings=path.to.settings i18n.tests.TranslationTests.test_lazy_objects
```

You can run tests starting at a specified top-level module with `--start-at` option. For example:

```
$ ./runtests.py --start-at=wsgi
```

You can also run tests starting after a specified top-level module with `--start-after` option. For example:

```
$ ./runtests.py --start-after=wsgi
```

Note that the `--reverse` option doesn't impact on `--start-at` or `--start-after` options. Moreover these options cannot be used with test labels.

Running the Selenium tests

Some tests require Selenium and a web browser. To run these tests, you must install the [selenium](#) package and run the tests with the `--selenium=<BROWSERS>` option. For example, if you have Firefox and Google Chrome installed:

```
$ ./runtests.py --selenium=firefox,chrome
```

See the [selenium.webdriver](#) package for the list of available browsers.

Specifying `--selenium` automatically sets `--tags=selenium` to run only the tests that require selenium.

Some browsers (e.g. Chrome or Firefox) support headless testing, which can be faster and more stable. Add the `--headless` option to enable this mode.

Running all the tests

If you want to run the full suite of tests, you'll need to install a number of dependencies:

- [aiosmtpd](#)
- [argon2-cffi](#) 19.2.0+
- [asgiref](#) 3.6.0+ (required)
- [bcrypt](#)
- [colorama](#)
- [docutils](#)
- [geoip2](#)
- [Jinja2](#) 2.11+
- [numpy](#)
- [Pillow](#) 6.2.1+
- [PyYAML](#)
- [pytz](#) (required)
- [pywatchman](#)
- [redis](#) 3.4+
- [setuptools](#)
- [python-memcached](#), plus a supported Python binding
- [gettext](#) ([gettext on Windows](#))
- [selenium](#) 3.8.0+

- [sqlparse](#) 0.3.1+ (required)
- [tblib](#) 1.5.0+

You can find these dependencies in [pip requirements files](#) inside the `tests/requirements` directory of the Django source tree and install them like so:

```
$ python -m pip install -r tests/requirements/py3.txt
```

If you encounter an error during the installation, your system might be missing a dependency for one or more of the Python packages. Consult the failing package's documentation or search the web with the error message that you encounter.

You can also install the database adapter(s) of your choice using `oracle.txt`, `mysql.txt`, or `postgres.txt`.

If you want to test the memcached or Redis cache backends, you'll also need to define a [CACHES](#) setting that points at your memcached or Redis instance respectively.

To run the GeoDjango tests, you will need to [set up a spatial database and install the Geospatial libraries](#).

Each of these dependencies is optional. If you're missing any of them, the associated tests will be skipped.

To run some of the autoreload tests, you'll need to install the [Watchman](#) service.

Code coverage

Contributors are encouraged to run coverage on the test suite to identify areas that need additional tests. The coverage tool installation and use is described in [testing code coverage](#).

Coverage should be run in a single process to obtain accurate statistics. To run coverage on the Django test suite using the standard test settings:

```
$ coverage run ./runtests.py --settings=test_sqlite --parallel=1
```

After running coverage, generate the html report by running:

```
$ coverage html
```

When running coverage for the Django tests, the included `.coveragerc` settings file defines `coverage_html` as the output directory for the report and also excludes several directories not relevant to the results (test code or external code included in Django).

Contrib apps

Tests for contrib apps can be found in the `tests/` directory, typically under `<app_name>_tests`. For example, tests for `contrib.auth` are located in `tests/auth_tests`.

Troubleshooting

Test suite hangs or shows failures on main branch

Ensure you have the latest point release of a [supported Python version](#), since there are often bugs in earlier versions that may cause the test suite to fail or hang.

On macOS (High Sierra and newer versions), you might see this message logged, after which the tests hang:

```
objc[42074]: +[__NSPlaceholderDate initialize] may have been in progress in
another thread when fork() was called.
```

To avoid this set a `OBJC_DISABLE_INITIALIZE_FORK_SAFETY` environment variable, for example:

```
$ OBJC_DISABLE_INITIALIZE_FORK_SAFETY=YES ./runtests.py
```

Or add `export OBJC_DISABLE_INITIALIZE_FORK_SAFETY=YES` to your shell's startup file (e.g. `~/.profile`).

Many test failures with `UnicodeEncodeError`

If the `locales` package is not installed, some tests will fail with a `UnicodeEncodeError`.

You can resolve this on Debian-based systems, for example, by running:

```
$ apt-get install locales
$ dpkg-reconfigure locales
```

You can resolve this for macOS systems by configuring your shell's locale:

```
$ export LANG="en_US.UTF-8"
$ export LC_ALL="en_US.UTF-8"
```

Run the `locale` command to confirm the change. Optionally, add those export commands to your shell's startup file (e.g. `~/.bashrc` for Bash) to avoid having to retype them.

Tests that only fail in combination

In case a test passes when run in isolation but fails within the whole suite, we have some tools to help analyze the problem.

The `--bisect` option of `runtests.py` will run the failing test while halving the test set it is run together with on each iteration, often making it possible to identify a small number of tests that may be related to the failure.

For example, suppose that the failing test that works on its own is `ModelTest.test_eq`, then using:

```
$ ./runtests.py --bisect basic.tests.ModelTest.test_eq
```

will try to determine a test that interferes with the given one. First, the test is run with the first half of the test suite. If a failure occurs, the first half of the test suite is split in two groups and each group is then run with the specified test. If there is no failure with the first half of the test suite, the second half of the test suite is run with the specified test and split appropriately as described earlier. The process repeats until the set of failing tests is minimized.

The `--pair` option runs the given test alongside every other test from the suite, letting you check if another test has side-effects that cause the failure. So:

```
$ ./runtests.py --pair basic.tests.ModelTest.test_eq
```

will pair `test_eq` with every test label.

With both `--bisect` and `--pair`, if you already suspect which cases might be responsible for the failure, you may limit tests to be cross-analyzed by [specifying further test labels](#) after the first one:

```
$ ./runtests.py --pair basic.tests.ModelTest.test_eq queries transactions
```

You can also try running any set of tests in a random or reverse order using the `--shuffle` and `--reverse` options. This can help verify that executing tests in a different order does not cause any trouble:

```
$ ./runtests.py basic --shuffle
$ ./runtests.py basic --reverse
```

Seeing the SQL queries run during a test

If you wish to examine the SQL being run in failing tests, you can turn on [SQL logging](#) using the `--debug-sql` option. If you combine this with `--verbosity=2`, all SQL queries will be output:

```
$ ./runtests.py basic --debug-sql
```

Seeing the full traceback of a test failure

By default tests are run in parallel with one process per core. When the tests are run in parallel, however, you'll only see a truncated traceback for any test failures. You can adjust this behavior with the `--parallel` option:

```
$ ./runtests.py basic --parallel=1
```

You can also use the `DJANGO_TEST_PROCESSES` environment variable for this purpose.

Tips for writing tests

Isolating model registration

To avoid polluting the global `apps` registry and prevent unnecessary table creation, models defined in a test method should be bound to a temporary `Apps` instance. To do this, use the `isolate_apps()` decorator:

```
from django.db import models
from django.test import SimpleTestCase
from django.test.utils import isolate_apps

class TestModelDefinition(SimpleTestCase):
    @isolate_apps("app_label")
    def test_model_definition(self):
        class TestModel(models.Model):
            pass

        ...
```

Setting `app_label`

Models defined in a test method with no explicit `app_label` are automatically assigned the label of the app in which their test class is located.

In order to make sure the models defined within the context of `isolate_apps()` instances are correctly installed, you should pass the set of targeted `app_label` as arguments:

Listing 2: tests/app_label/tests.py

```
from django.db import models
from django.test import SimpleTestCase
from django.test.utils import isolate_apps
```

(continues on next page)

(continued from previous page)

```
class TestModelDefinition(SimpleTestCase):
    @isolate_apps("app_label", "other_app_label")
    def test_model_definition(self):
        # This model automatically receives app_label='app_label'
        class TestModel(models.Model):
            pass

        class OtherAppModel(models.Model):
            class Meta:
                app_label = "other_app_label"

        ...
```

Submitting patches

We’re always grateful for patches to Django’s code. Indeed, bug reports with associated patches will get fixed far more quickly than those without patches.

Typo fixes and trivial documentation changes

If you are fixing a really trivial issue, for example changing a word in the documentation, the preferred way to provide the patch is using GitHub pull requests without a Trac ticket.

See the [Working with Git and GitHub](#) for more details on how to use pull requests.

“Claiming” tickets

In an open-source project with hundreds of contributors around the world, it’s important to manage communication efficiently so that work doesn’t get duplicated and contributors can be as effective as possible.

Hence, our policy is for contributors to “claim” tickets in order to let other developers know that a particular bug or feature is being worked on.

If you have identified a contribution you want to make and you’re capable of fixing it (as measured by your coding ability, knowledge of Django internals and time availability), claim it by following these steps:

- [Login using your GitHub account](#) or [create an account](#) in our ticket system. If you have an account but have forgotten your password, you can reset it using the [password reset page](#).
- If a ticket for this issue doesn’t exist yet, create one in our [ticket tracker](#).

- If a ticket for this issue already exists, make sure nobody else has claimed it. To do this, look at the “Owned by” section of the ticket. If it’s assigned to “nobody,” then it’s available to be claimed. Otherwise, somebody else may be working on this ticket. Either find another bug/feature to work on, or contact the developer working on the ticket to offer your help. If a ticket has been assigned for weeks or months without any activity, it’s probably safe to reassign it to yourself.
- Log into your account, if you haven’t already, by clicking “GitHub Login” or “DjangoProject Login” in the upper left of the ticket page.
- Claim the ticket by clicking the “assign to myself” radio button under “Action” near the bottom of the page, then click “Submit changes.”

Note: The Django software foundation requests that anyone contributing more than a trivial patch to Django sign and submit a [Contributor License Agreement](#), this ensures that the Django Software Foundation has clear license to all contributions allowing for a clear license for all users.

Ticket claimers’ responsibility

Once you’ve claimed a ticket, you have a responsibility to work on that ticket in a reasonably timely fashion. If you don’t have time to work on it, either unclaim it or don’t claim it in the first place!

If there’s no sign of progress on a particular claimed ticket for a week or two, another developer may ask you to relinquish the ticket claim so that it’s no longer monopolized and somebody else can claim it.

If you’ve claimed a ticket and it’s taking a long time (days or weeks) to code, keep everybody updated by posting comments on the ticket. If you don’t provide regular updates, and you don’t respond to a request for a progress report, your claim on the ticket may be revoked.

As always, more communication is better than less communication!

Which tickets should be claimed?

Going through the steps of claiming tickets is overkill in some cases.

In the case of small changes, such as typos in the documentation or small bugs that will only take a few minutes to fix, you don’t need to jump through the hoops of claiming tickets. Submit your patch directly and you’re done!

It is always acceptable, regardless whether someone has claimed it or not, to submit patches to a ticket if you happen to have a patch ready.

Patch style

Make sure that any contribution you do fulfills at least the following requirements:

- The code required to fix a problem or add a feature is an essential part of a patch, but it is not the only part. A good patch should also include a [regression test](#) to validate the behavior that has been fixed and to prevent the problem from arising again. Also, if some tickets are relevant to the code that you’ve written, mention the ticket numbers in some comments in the test so that one can easily trace back the relevant discussions after your patch gets committed, and the tickets get closed.
- If the code associated with a patch adds a new feature, or modifies behavior of an existing feature, the patch should also contain documentation.

When you think your work is ready to be reviewed, send a [GitHub pull request](#). Please review the patch yourself using our [patch review checklist](#) first.

If you can’t send a pull request for some reason, you can also use patches in Trac. When using this style, follow these guidelines.

- Submit patches in the format returned by the `git diff` command.
- Attach patches to a ticket in the [ticket tracker](#), using the “attach file” button. Please don’t put the patch in the ticket description or comment unless it’s a single line patch.
- Name the patch file with a `.diff` extension; this will let the ticket tracker apply correct syntax highlighting, which is quite helpful.

Regardless of the way you submit your work, follow these steps.

- Make sure your code fulfills the requirements in our [patch review checklist](#).
- Check the “Has patch” box on the ticket and make sure the “Needs documentation”, “Needs tests”, and “Patch needs improvement” boxes aren’t checked. This makes the ticket appear in the “Patches needing review” queue on the [Development dashboard](#).

Non-trivial patches

A “non-trivial” patch is one that is more than a small bug fix. It’s a patch that introduces Django functionality and makes some sort of design decision.

If you provide a non-trivial patch, include evidence that alternatives have been discussed on the [Django Forum](#) or [django-developers](#) list.

If you’re not sure whether your patch should be considered non-trivial, ask on the ticket for opinions.

Deprecating a feature

There are a couple of reasons that code in Django might be deprecated:

- If a feature has been improved or modified in a backwards-incompatible way, the old feature or behavior will be deprecated.
- Sometimes Django will include a backport of a Python library that's not included in a version of Python that Django currently supports. When Django no longer needs to support the older version of Python that doesn't include the library, the library will be deprecated in Django.

As the [deprecation policy](#) describes, the first release of Django that deprecates a feature (A.B) should raise a `RemovedInDjangoXXWarning` (where XX is the Django version where the feature will be removed) when the deprecated feature is invoked. Assuming we have good test coverage, these warnings are converted to errors when [running the test suite](#) with warnings enabled: `python -Wa runtests.py`. Thus, when adding a `RemovedInDjangoXXWarning` you need to eliminate or silence any warnings generated when running the tests.

The first step is to remove any use of the deprecated behavior by Django itself. Next you can silence warnings in tests that actually test the deprecated behavior by using the `ignore_warnings` decorator, either at the test or class level:

- 1) In a particular test:

```
from django.test import ignore_warnings
from django.utils.deprecation import RemovedInDjangoXXWarning

@ignore_warnings(category=RemovedInDjangoXXWarning)
def test_foo(self):
    ...
```

- 2) For an entire test case:

```
from django.test import ignore_warnings
from django.utils.deprecation import RemovedInDjangoXXWarning

@ignore_warnings(category=RemovedInDjangoXXWarning)
class MyDeprecatedTests(unittest.TestCase):
    ...
```

You should also add a test for the deprecation warning:

```
from django.utils.deprecation import RemovedInDjangoXXWarning
```

(continues on next page)

(continued from previous page)

```
def test_foo_deprecation_warning(self):
    msg = "Expected deprecation message"
    with self.assertWarnsMessage(RemovedInDjangoXXWarning, msg):
        # invoke deprecated behavior
        ...
```

It’s important to include a `RemovedInDjangoXXWarning` comment above code which has no warning reference, but will need to be changed or removed when the deprecation ends. This could include hooks which have been added to keep the previous behavior, or standalone items that are unnecessary or unused when the deprecation ends. For example:

```
import warnings
from django.utils.deprecation import RemovedInDjangoXXWarning

# RemovedInDjangoXXWarning.
def old_private_helper():
    # Helper function that is only used in foo().
    pass

def foo():
    warnings.warn(
        "foo() is deprecated.",
        category=RemovedInDjangoXXWarning,
    )
    old_private_helper()
    ...
```

Finally, there are a couple of updates to Django’s documentation to make:

- 1) If the existing feature is documented, mark it deprecated in documentation using the `.. deprecated:: A.B` annotation. Include a short description and a note about the upgrade path if applicable.
- 2) Add a description of the deprecated behavior, and the upgrade path if applicable, to the current release notes (`docs/releases/A.B.txt`) under the “Features deprecated in A.B” heading.
- 3) Add an entry in the deprecation timeline (`docs/internals/deprecation.txt`) under the appropriate version describing what code will be removed.

Once you have completed these steps, you are finished with the deprecation. In each [feature release](#), all `RemovedInDjangoXXWarnings` matching the new version are removed.

JavaScript patches

For information on JavaScript patches, see the [JavaScript patches](#) documentation.

Patch review checklist

Use this checklist to review a pull request. If you are reviewing a pull request that is not your own and it passes all the criteria below, please set the “Triage Stage” on the corresponding Trac ticket to “Ready for checkin”. If you’ve left comments for improvement on the pull request, please tick the appropriate flags on the Trac ticket based on the results of your review: “Patch needs improvement”, “Needs documentation”, and/or “Needs tests”. As time and interest permits, mergers do final reviews of “Ready for checkin” tickets and will either commit the patch or bump it back to “Accepted” if further works need to be done. If you’re looking to become a merger, doing thorough reviews of patches is a great way to earn trust.

Looking for a patch to review? Check out the “Patches needing review” section of the [Django Development Dashboard](#). Looking to get your patch reviewed? Ensure the Trac flags on the ticket are set so that the ticket appears in that queue.

Documentation

- Does the documentation build without any errors (`make html`, or `make.bat html` on Windows, from the `docs` directory)?
- Does the documentation follow the writing style guidelines in [Writing documentation](#)?
- Are there any [spelling errors](#)?

Bugs

- Is there a proper regression test (the test should fail before the fix is applied)?
- If it’s a bug that [qualifies for a backport](#) to the stable version of Django, is there a release note in `docs/releases/A.B.C.txt`? Bug fixes that will be applied only to the main branch don’t need a release note.

New Features

- Are there tests to “exercise” all of the new code?
- Is there a release note in `docs/releases/A.B.txt`?
- Is there documentation for the feature and is it [annotated appropriately](#) with `.. versionadded:: A.B` or `.. versionchanged:: A.B`?

Deprecating a feature

See the [Deprecating a feature](#) guide.

All code changes

- Does the [coding style](#) conform to our guidelines? Are there any `black`, `blacken-docs`, `flake8`, or `isort` errors? You can install the [pre-commit](#) hooks to automatically catch these errors.
- If the change is backwards incompatible in any way, is there a note in the release notes (`docs/releases/A.B.txt`)?
- Is Django's test suite passing?

All tickets

- Is the pull request a single squashed commit with a message that follows our [commit message format](#)?
- Are you the patch author and a new contributor? Please add yourself to the [AUTHORS](#) file and submit a [Contributor License Agreement](#).

Working with Git and GitHub

This section explains how the community can contribute code to Django via pull requests. If you're interested in how [mergers](#) handle them, see [Committing code](#).

Below, we are going to show how to create a GitHub pull request containing the changes for Trac ticket #xxxxxx. By creating a fully-ready pull request, you will make the reviewer's job easier, meaning that your work is more likely to be merged into Django.

You could also upload a traditional patch to Trac, but it's less practical for reviews.

Installing Git

Django uses [Git](#) for its source control. You can [download](#) Git, but it's often easier to install with your operating system's package manager.

Django's [Git repository](#) is hosted on [GitHub](#), and it is recommended that you also work using GitHub.

After installing Git, the first thing you should do is set up your name and email:

```
$ git config --global user.name "Your Real Name"
$ git config --global user.email "you@email.com"
```

Note that `user.name` should be your real name, not your GitHub nick. GitHub should know the email you use in the `user.email` field, as this will be used to associate your commits with your GitHub account.

Setting up local repository

When you have created your GitHub account, with the nick “GitHub_nick”, and [forked Django’s repository](#), create a local copy of your fork:

```
git clone https://github.com/GitHub_nick/django.git
```

This will create a new directory “django”, containing a clone of your GitHub repository. The rest of the git commands on this page need to be run within the cloned directory, so switch to it now:

```
cd django
```

Your GitHub repository will be called “origin” in Git.

You should also set up `django/django` as an “upstream” remote (that is, tell git that the reference Django repository was the source of your fork of it):

```
git remote add upstream https://github.com/django/django.git
git fetch upstream
```

You can add other remotes similarly, for example:

```
git remote add akaariai https://github.com/akaariai/django.git
```

Working on a ticket

When working on a ticket, create a new branch for the work, and base that work on `upstream/main`:

```
git checkout -b ticket_xxxxx upstream/main
```

The `-b` flag creates a new branch for you locally. Don’t hesitate to create new branches even for the smallest things - that’s what they are there for.

If instead you were working for a fix on the 1.4 branch, you would do:

```
git checkout -b ticket_xxxxx_1_4 upstream/stable/1.4.x
```

Assume the work is carried on the `ticket_xxxxx` branch. Make some changes and commit them:

```
git commit
```

When writing the commit message, follow the [commit message guidelines](#) to ease the work of the merger. If you're uncomfortable with English, try at least to describe precisely what the commit does.

If you need to do additional work on your branch, commit as often as necessary:

```
git commit -m 'Added two more tests for edge cases'
```

Publishing work

You can publish your work on GitHub by running:

```
git push origin ticket_XXXXX
```

When you go to your GitHub page, you will notice a new branch has been created.

If you are working on a Trac ticket, you should mention in the ticket that your work is available from branch `ticket_XXXXX` of your GitHub repo. Include a link to your branch.

Note that the above branch is called a “topic branch” in Git parlance. You are free to rewrite the history of this branch, by using `git rebase` for example. Other people shouldn't base their work on such a branch, because their clone would become corrupt when you edit commits.

There are also “public branches”. These are branches other people are supposed to fork, so the history of these branches should never change. Good examples of public branches are the `main` and `stable/A.B.x` branches in the `django/django` repository.

When you think your work is ready to be pulled into Django, you should create a pull request at GitHub. A good pull request means:

- commits with one logical change in each, following the [coding style](#),
- well-formed messages for each commit: a summary line and then paragraphs wrapped at 72 characters thereafter –see the [committing guidelines](#) for more details,
- documentation and tests, if needed –actually tests are always needed, except for documentation changes.

The test suite must pass and the documentation must build without warnings.

Once you have created your pull request, you should add a comment in the related Trac ticket explaining what you've done. In particular, you should note the environment in which you ran the tests, for instance: “all tests pass under SQLite and MySQL” .

Pull requests at GitHub have only two states: open and closed. The merger who will deal with your pull request has only two options: merge it or close it. For this reason, it isn't useful to make a pull request until the code is ready for merging –or sufficiently close that a merger will finish it themselves.

Rebasing branches

In the example above, you created two commits, the “Fixed ticket_xxxxx” commit and “Added two more tests” commit.

We do not want to have the entire history of your working process in your repository. Your commit “Added two more tests” would be unhelpful noise. Instead, we would rather only have one commit containing all your work.

To rework the history of your branch you can squash the commits into one by using interactive rebase:

```
git rebase -i HEAD~2
```

The HEAD~2 above is shorthand for two latest commits. The above command will open an editor showing the two commits, prefixed with the word “pick” .

Change “pick” on the second line to “squash” instead. This will keep the first commit, and squash the second commit into the first one. Save and quit the editor. A second editor window should open, so you can reword the commit message for the commit now that it includes both your steps.

You can also use the “edit” option in rebase. This way you can change a single commit, for example to fix a typo in a docstring:

```
git rebase -i HEAD~3
# Choose edit, pick, pick for the commits
# Now you are able to rework the commit (use git add normally to add changes)
# When finished, commit work with "--amend" and continue
git commit --amend
# Reword the commit message if needed
git rebase --continue
# The second and third commits should be applied.
```

If your topic branch is already published at GitHub, for example if you’ re making minor changes to take into account a review, you will need to force-push the changes:

```
git push -f origin ticket_xxxxx
```

Note that this will rewrite history of ticket_xxxxx - if you check the commit hashes before and after the operation at GitHub you will notice that the commit hashes do not match anymore. This is acceptable, as the branch is a topic branch, and nobody should be basing their work on it.

After upstream has changed

When upstream (django/django) has changed, you should rebase your work. To do this, use:

```
git fetch upstream
git rebase upstream/main
```

The work is automatically rebased using the branch you forked on, in the example case using `upstream/main`.

The rebase command removes all your local commits temporarily, applies the upstream commits, and then applies your local commits again on the work.

If there are merge conflicts, you will need to resolve them and then use `git rebase --continue`. At any point you can use `git rebase --abort` to return to the original state.

Note that you want to rebase on upstream, not merge the upstream.

The reason for this is that by rebasing, your commits will always be on top of the upstream's work, not mixed in with the changes in the upstream. This way your branch will contain only commits related to its topic, which makes squashing easier.

After review

It is unusual to get any non-trivial amount of code into core without changes requested by reviewers. In this case, it is often a good idea to add the changes as one incremental commit to your work. This allows the reviewer to easily check what changes you have done.

In this case, do the changes required by the reviewer. Commit as often as necessary. Before publishing the changes, rebase your work. If you added two commits, you would run:

```
git rebase -i HEAD~2
```

Squash the second commit into the first. Write a commit message along the lines of:

```
Made changes asked in review by <reviewer>

- Fixed whitespace errors in foobar
- Reworded the docstring of bar()
```

Finally, push your work back to your GitHub repository. Since you didn't touch the public commits during the rebase, you should not need to force-push:

```
git push origin ticket_XXXXX
```

Your pull request should now contain the new commit too.

Note that the merger is likely to squash the review commit into the previous commit when committing the code.

Working on a patch

One of the ways that developers can contribute to Django is by reviewing patches. Those patches will typically exist as pull requests on GitHub and can be easily integrated into your local repository:

```
git checkout -b pull_XXXXX upstream/main
curl -L https://github.com/django/django/pull/XXXXX.patch | git am
```

This will create a new branch and then apply the changes from the pull request to it. At this point you can run the tests or do anything else you need to do to investigate the quality of the patch.

For more detail on working with pull requests see the [guidelines for mergers](#).

Summary

- Work on GitHub if you can.
- Announce your work on the Trac ticket by linking to your GitHub branch.
- When you have something ready, make a pull request.
- Make your pull requests as good as you can.
- When doing fixes to your work, use `git rebase -i` to squash the commits.
- When upstream has changed, do `git fetch upstream`; `git rebase`.

JavaScript

While most of Django core is Python, the `admin` and `gis` contrib apps contain JavaScript code.

Please follow these coding standards when writing JavaScript code for inclusion in Django.

Code style

- Please conform to the indentation style dictated in the `.editorconfig` file. We recommend using a text editor with [EditorConfig](#) support to avoid indentation and whitespace issues. Most of the JavaScript files use 4 spaces for indentation, but there are some exceptions.
- When naming variables, use `camelCase` instead of `underscore_case`. Different JavaScript files sometimes use a different code style. Please try to conform to the code style of each file.

- Use the [ESLint](#) code linter to check your code for bugs and style errors. ESLint will be run when you run the JavaScript tests. We also recommended installing a ESLint plugin in your text editor.
- Where possible, write code that will work even if the page structure is later changed with JavaScript. For instance, when binding a click handler, use `$('#body').on('click', selector, func)` instead of `$(selector).click(func)`. This makes it easier for projects to extend Django's default behavior with JavaScript.

JavaScript patches

Django's admin system leverages the jQuery framework to increase the capabilities of the admin interface. In conjunction, there is an emphasis on admin JavaScript performance and minimizing overall admin media file size.

JavaScript tests

Django's JavaScript tests can be run in a browser or from the command line. The tests are located in a top level `js_tests` directory.

Writing tests

Django's JavaScript tests use [QUnit](#). Here is an example test module:

```
QUnit.module('magicTricks', {
  beforeEach: function() {
    const $ = django.jQuery;
    $('#qunit-fixture').append('<button class="button"></button>');
  }
});

QUnit.test('removeOnClick removes button on click', function(assert) {
  const $ = django.jQuery;
  removeOnClick('.button');
  assert.equal($('.button').length, 1);
  $('.button').click();
  assert.equal($('.button').length, 0);
});

QUnit.test('copyOnClick adds button on click', function(assert) {
  const $ = django.jQuery;
  copyOnClick('.button');
  assert.equal($('.button').length, 1);
});
```

(continues on next page)

(continued from previous page)

```
$('.button').click();
assert.equal($('.button').length, 2);
});
```

Please consult the `QUnit` documentation for information on the types of [assertions](#) supported by `QUnit`.

Running tests

The JavaScript tests may be run from a web browser or from the command line.

Testing from a web browser

To run the tests from a web browser, open up `js_tests/tests.html` in your browser.

To measure code coverage when running the tests, you need to view that file over HTTP. To view code coverage:

- Execute `python -m http.server` from the root directory (not from inside `js_tests`).
- Open `http://localhost:8000/js_tests/tests.html` in your web browser.

Testing from the command line

To run the tests from the command line, you need to have `Node.js` installed.

After installing `Node.js`, install the JavaScript test dependencies by running the following from the root of your Django checkout:

```
$ npm install
```

Then run the tests with:

```
$ npm test
```

Writing documentation

We place high importance on the consistency and readability of documentation. After all, Django was created in a journalism environment! So we treat our documentation like we treat our code: we aim to improve it as often as possible.

Documentation changes generally come in two forms:

- General improvements: typo corrections, error fixes and better explanations through clearer writing and more examples.

- New features: documentation of features that have been added to the framework since the last release.

This section explains how writers can craft their documentation changes in the most useful and least error-prone ways.

Getting the raw documentation

Though Django’s documentation is intended to be read as HTML at <https://docs.djangoproject.com/>, we edit it as a collection of text files for maximum flexibility. These files live in the top-level `docs/` directory of a Django release.

If you’d like to start contributing to our docs, get the development version of Django from the source code repository (see [Installing the development version](#)). The development version has the latest-and-greatest documentation, just as it has the latest-and-greatest code. We also backport documentation fixes and improvements, at the discretion of the merger, to the last release branch. That’s because it’s highly advantageous to have the docs for the last release be up-to-date and correct (see [Differences between versions](#)).

Getting started with Sphinx

Django’s documentation uses the [Sphinx](#) documentation system, which in turn is based on [docutils](#). The basic idea is that lightly-formatted plain-text documentation is transformed into HTML, PDF, and any other output format.

To build the documentation locally, install Sphinx:

```
$ python -m pip install Sphinx
```

Then from the `docs` directory, build the HTML:

```
$ make html
```

To get started contributing, you’ll want to read the [reStructuredText reference](#).

Your locally-built documentation will be accessible at `docs/_build/html/index.html` and it can be viewed in any web browser, though it will be themed differently than the documentation at docs.djangoproject.com. This is OK! If your changes look good on your local machine, they’ll look good on the website.

How the documentation is organized

The documentation is organized into several categories:

- **Tutorials** take the reader by the hand through a series of steps to create something.

The important thing in a tutorial is to help the reader achieve something useful, preferably as early as possible, in order to give them confidence.

Explain the nature of the problem we're solving, so that the reader understands what we're trying to achieve. Don't feel that you need to begin with explanations of how things work - what matters is what the reader does, not what you explain. It can be helpful to refer back to what you've done and explain afterward.

- **Topic guides** aim to explain a concept or subject at a fairly high level.

Link to reference material rather than repeat it. Use examples and don't be reluctant to explain things that seem very basic to you - it might be the explanation someone else needs.

Providing background context helps a newcomer connect the topic to things that they already know.

- **Reference guides** contain technical references for APIs. They describe the functioning of Django's internal machinery and instruct in its use.

Keep reference material tightly focused on the subject. Assume that the reader already understands the basic concepts involved but needs to know or be reminded of how Django does it.

Reference guides aren't the place for general explanation. If you find yourself explaining basic concepts, you may want to move that material to a topic guide.

- **How-to guides** are recipes that take the reader through steps in key subjects.

What matters most in a how-to guide is what a user wants to achieve. A how-to should always be result-oriented rather than focused on internal details of how Django implements whatever is being discussed.

These guides are more advanced than tutorials and assume some knowledge about how Django works. Assume that the reader has followed the tutorials and don't hesitate to refer the reader back to the appropriate tutorial rather than repeat the same material.

Writing style

When using pronouns in reference to a hypothetical person, such as "a user with a session cookie", gender-neutral pronouns (they/their/them) should be used. Instead of:

- he or she... use they.
- him or her... use them.
- his or her... use their.

- his or hers. . . use theirs.
- himself or herself. . . use themselves.

Try to avoid using words that minimize the difficulty involved in a task or operation, such as “easily” , “simply” , “just” , “merely” , “straightforward” , and so on. People’ s experience may not match your expectations, and they may become frustrated when they do not find a step as “straightforward” or “simple” as it is implied to be.

Commonly used terms

Here are some style guidelines on commonly used terms throughout the documentation:

- Django –when referring to the framework, capitalize Django. It is lowercase only in Python code and in the djangoproject.com logo.
- email –no hyphen.
- HTTP –the expected pronunciation is “Aitch Tee Tee Pee” and therefore should be preceded by “an” and not “a” .
- MySQL, PostgreSQL, SQLite
- SQL –when referring to SQL, the expected pronunciation should be “Ess Queue Ell” and not “sequel” . Thus in a phrase like “Returns an SQL expression” , “SQL” should be preceded by “an” and not “a” .
- Python –when referring to the language, capitalize Python.
- realize, customize, initialize, etc. –use the American “ize” suffix, not “ise.”
- subclass –it’ s a single word without a hyphen, both as a verb (“subclass that model”) and as a noun (“create a subclass”).
- the web, web framework –it’ s not capitalized.
- website –use one word, without capitalization.

Django-specific terminology

- model –it’ s not capitalized.
- template –it’ s not capitalized.
- URLconf –use three capitalized letters, with no space before “conf.”
- view –it’ s not capitalized.

Guidelines for reStructuredText files

These guidelines regulate the format of our reST (reStructuredText) documentation:

- In section titles, capitalize only initial words and proper nouns.
- Wrap the documentation at 80 characters wide, unless a code example is significantly less readable when split over two lines, or for another good reason.
- The main thing to keep in mind as you write and edit docs is that the more semantic markup you can add the better. So:

```
Add ``django.contrib.auth`` to your ``INSTALLED_APPS``...
```

Isn't nearly as helpful as:

```
Add :mod:`django.contrib.auth` to your :setting:`INSTALLED_APPS`...
```

This is because Sphinx will generate proper links for the latter, which greatly helps readers.

You can prefix the target with a ~ (that's a tilde) to get only the “last bit” of that path. So `:mod:`~django.contrib.auth`` will display a link with the title “auth”.

- All Python code blocks should be formatted using the `blacken-docs` auto-formatter. This will be run by `pre-commit` if that is configured.
- Use `intersphinx` to reference Python's and Sphinx's documentation.
- Add `.. code-block:: <lang>` to literal blocks so that they get highlighted. Prefer relying on automatic highlighting using `::` (two colons). This has the benefit that if the code contains some invalid syntax, it won't be highlighted. Adding `.. code-block:: python`, for example, will force highlighting despite invalid syntax.
- To improve readability, use `.. admonition:: Descriptive title` rather than `.. note::`. Use these boxes sparingly.
- Use these heading styles:

```
===
One
===

Two
===

Three
-----
```

(continues on next page)

(continued from previous page)

```
Four
~~~~

Five
~~~~
```

- Use `:rfc:` to reference RFC and try to link to the relevant section if possible. For example, use `:rfc:`2324#section-2.3.2`` or `:rfc:`Custom link text <2324#section-2.3.2>``.
- Use `:pep:` to reference a Python Enhancement Proposal (PEP) and try to link to the relevant section if possible. For example, use `:pep:`20#easter-egg`` or `:pep:`Easter Egg <20#easter-egg>``.
- Use `:mimetype:` to refer to a MIME Type unless the value is quoted for a code example.
- Use `:envvar:` to refer to an environment variable. You may also need to define a reference to the documentation for that environment variable using `.. envvar::`.

All Python code blocks in the Django documentation were reformatted with `blacken-docs`.

Django-specific markup

Besides Sphinx' s built-in markup, Django' s docs define some extra description units:

- Settings:

```
.. setting:: INSTALLED_APPS
```

To link to a setting, use `:setting:`INSTALLED_APPS``.

- Template tags:

```
.. templatetag:: regroup
```

To link, use `:ttag:`regroup``.

- Template filters:

```
.. templatefilter:: linebreaksbr
```

To link, use `:tfilter:`linebreaksbr``.

- Field lookups (i.e. `Foo.objects.filter(bar__exact=whatever)`):

```
.. fieldlookup:: exact
```

To link, use `:lookup:`exact``.

- django-admin commands:

```
.. django-admin:: migrate
```

To link, use `:djadmin:`migrate``.

- `django-admin` command-line options:

```
.. django-admin-option:: --traceback
```

To link, use `:option:`command_name --traceback`` (or omit `command_name` for the options shared by all commands like `--verbosity`).

- Links to Trac tickets (typically reserved for patch release notes):

```
:ticket:`12345`
```

Django's documentation uses a custom `console` directive for documenting command-line examples involving `django-admin`, `manage.py`, `python`, etc.). In the HTML documentation, it renders a two-tab UI, with one tab showing a Unix-style command prompt and a second tab showing a Windows prompt.

For example, you can replace this fragment:

```
use this command:

.. code-block:: console

    $ python manage.py shell
```

with this one:

```
use this command:

.. console::

    $ python manage.py shell
```

Notice two things:

- You usually will replace occurrences of the `.. code-block:: console` directive.
- You don't need to change the actual content of the code example. You still write it assuming a Unix-y environment (i.e. a `'$'` prompt symbol, `'/'` as filesystem path components separator, etc.)

The example above will render a code example block with two tabs. The first one will show:

```
$ python manage.py shell
```

(No changes from what `.. code-block:: console` would have rendered).

The second one will show:

```
...> py manage.py shell
```

Documenting new features

Our policy for new features is:

All documentation of new features should be written in a way that clearly designates the features that are only available in the Django development version. Assume documentation readers are using the latest release, not the development version.

Our preferred way for marking new features is by prefacing the features' documentation with: “`.. versionadded:: X.Y`”, followed by a mandatory blank line and an optional description (indented).

General improvements or other changes to the APIs that should be emphasized should use the “`.. versionchanged:: X.Y`” directive (with the same format as the `versionadded` mentioned above).

These `versionadded` and `versionchanged` blocks should be “self-contained.” In other words, since we only keep these annotations around for two releases, it's nice to be able to remove the annotation and its contents without having to reflow, reindent, or edit the surrounding text. For example, instead of putting the entire description of a new or changed feature in a block, do something like this:

```
.. class:: Author(first_name, last_name, middle_name=None)

    A person who writes books.

    ``first_name`` is ...

    ...

    ``middle_name`` is ...

    .. versionchanged:: A.B

        The ``middle_name`` argument was added.
```

Put the changed annotation notes at the bottom of a section, not the top.

Also, avoid referring to a specific version of Django outside a `versionadded` or `versionchanged` block. Even inside a block, it's often redundant to do so as these annotations render as “New in Django A.B:” and “Changed in Django A.B”, respectively.

If a function, attribute, etc. is added, it's also okay to use a `versionadded` annotation like this:

```
.. attribute:: Author.middle_name
```

(continues on next page)

(continued from previous page)

```
.. versionadded:: A.B
```

```
An author's middle name.
```

We can remove the `.. versionadded:: A.B` annotation without any indentation changes when the time comes.

Minimizing images

Optimize image compression where possible. For PNG files, use OptiPNG and AdvanceCOMP's `advpng`:

```
$ cd docs
$ optipng -o7 -zm1-9 -i0 -strip all `find . -type f -not -path "./_build/*" -name "*.png"`
$ advpng -z4 `find . -type f -not -path "./_build/*" -name "*.png"`
```

This is based on OptiPNG version 0.7.5. Older versions may complain about the `-strip all` option being lossy.

An example

For a quick example of how it all fits together, consider this hypothetical example:

- First, the `ref/settings.txt` document could have an overall layout like this:

```
=====
Settings
=====

...

.. _available-settings:

Available settings
=====

...

.. _deprecated-settings:

Deprecated settings
=====

...
```

- Next, the `topics/settings.txt` document could contain something like this:

```
You can access a :ref:`listing of all available settings
<available-settings>`. For a list of deprecated settings see
:ref:`deprecated-settings`.

You can find both in the :doc:`settings reference document
</ref/settings>`.
```

We use the Sphinx `doc` cross-reference element when we want to link to another document as a whole and the `ref` element when we want to link to an arbitrary location in a document.

- Next, notice how the settings are annotated:

```
.. setting:: ADMINS

ADMINS
=====

Default: ``[]`` (Empty list)

A list of all the people who get code error notifications. When
``DEBUG=False`` and a view raises an exception, Django will email these people
with the full exception information. Each member of the list should be a tuple
of (Full name, email address). Example::

    [("John", "john@example.com"), ("Mary", "mary@example.com")]

Note that Django will email all of these people whenever an error happens.
See :doc:`/howto/error-reporting` for more information.
```

This marks up the following header as the “canonical” target for the setting `ADMINS`. This means any time I talk about `ADMINS`, I can reference it using `:setting:`ADMINS``.

That’s basically how everything fits together.

Spelling check

Before you commit your docs, it’s a good idea to run the spelling checker. You’ll need to install `sphinxcontrib-spelling` first. Then from the `docs` directory, run `make spelling`. Wrong words (if any) along with the file and line number where they occur will be saved to `_build/spelling/output.txt`.

If you encounter false-positives (error output that actually is correct), do one of the following:

- Surround inline code or brand/technology names with grave accents (```).
- Find synonyms that the spell checker recognizes.

- If, and only if, you are sure the word you are using is correct - add it to `docs/spelling_wordlist` (please keep the list in alphabetical order).

Link check

Links in documentation can become broken or changed such that they are no longer the canonical link. Sphinx provides a builder that can check whether the links in the documentation are working. From the `docs` directory, run `make linkcheck`. Output is printed to the terminal, but can also be found in `_build/linkcheck/output.txt` and `_build/linkcheck/output.json`.

Entries that have a status of “working” are fine, those that are “unchecked” or “ignored” have been skipped because they either cannot be checked or have matched ignore rules in the configuration.

Entries that have a status of “broken” need to be fixed. Those that have a status of “redirected” may need to be updated to point to the canonical location, e.g. the scheme has changed `http://` → `https://`. In certain cases, we do not want to update a “redirected” link, e.g. a rewrite to always point to the latest or stable version of the documentation, e.g. `/en/stable/` → `/en/3.2/`.

Translating documentation

See [Localizing the Django documentation](#) if you’d like to help translate the documentation into another language.

django-admin man page

Sphinx can generate a manual page for the `django-admin` command. This is configured in `docs/conf.py`. Unlike other documentation output, this man page should be included in the Django repository and the releases as `docs/man/django-admin.1`. There isn’t a need to update this file when updating the documentation, as it’s updated once as part of the release process.

To generate an updated version of the man page, run `make man` in the `docs` directory. The new man page will be written in `docs/_build/man/django-admin.1`.

Localizing Django

Various parts of Django, such as the admin site and validation error messages, are internationalized. This means they display differently depending on each user’s language or country. For this, Django uses the same internationalization and localization infrastructure available to Django applications, described in the [i18n documentation](#).

Translations

Translations are contributed by Django users worldwide. The translation work is coordinated at [Transifex](#).

If you find an incorrect translation or want to discuss specific translations, go to the [Django project page](#). If you would like to help out with translating or adding a language that isn't yet translated, here's what to do:

- Introduce yourself on the [Django internationalization forum](#).
- Make sure you read the notes about [Specialties of Django translation](#).
- Sign up at [Transifex](#) and visit the [Django project page](#).
- On the [Django project page](#), choose the language you want to work on, or –in case the language doesn't exist yet –request a new language team by clicking on the “Request language” link and selecting the appropriate language.
- Then, click the “Join this Team” button to become a member of this team. Every team has at least one coordinator who is responsible to review your membership request. You can also contact the team coordinator to clarify procedural problems and handle the actual translation process.
- Once you are a member of a team choose the translation resource you want to update on the team page. For example, the “core” resource refers to the translation catalog that contains all non-contrib translations. Each of the contrib apps also has a resource (prefixed with “contrib”).

Note: For more information about how to use Transifex, read the [Transifex User Guide](#).

Translations from Transifex are only integrated into the Django repository at the time of a new [feature release](#). We try to update them a second time during one of the following [patch releases](#), but that depends on the translation manager's availability. So don't miss the string freeze period (between the release candidate and the feature release) to take the opportunity to complete and fix the translations for your language!

Formats

You can also review `conf/locale/<locale>/formats.py`. This file describes the date, time and numbers formatting particularities of your locale. See [Format localization](#) for details.

The format files aren't managed by the use of Transifex. To change them, you must [create a patch](#) against the Django source tree, as for any code change:

- Create a diff against the current Git main branch.
- Open a ticket in Django's ticket system, set its **Component** field to **Translations**, and attach the patch to it.

Documentation

There is also an opportunity to translate the documentation, though this is a huge undertaking to complete entirely (you have been warned!). We use the same [Transifex tool](#). The translations will appear at https://docs.djangoproject.com/<language_code>/ when at least the docs/intro/* files are fully translated in your language.

Once translations are published, updated versions from Transifex will be irregularly ported to the [django/django-docs-translations](#) repository and to the documentation website. Only translations for the latest stable Django release are updated.

Committing code

This section is addressed to the mergers and to anyone interested in knowing how code gets committed into Django. If you're a community member who wants to contribute code to Django, look at [Working with Git and GitHub](#) instead.

Handling pull requests

Since Django is hosted on GitHub, patches are provided in the form of pull requests.

When committing a pull request, make sure each individual commit matches the commit guidelines described below. Contributors are expected to provide the best pull requests possible. In practice mergers - who will likely be more familiar with the commit guidelines - may decide to bring a commit up to standard themselves.

You may want to have Jenkins or GitHub actions test the pull request with one of the pull request builders that doesn't run automatically, such as Oracle or Selenium. See the [CI wiki page](#) for instructions.

If you find yourself checking out pull requests locally more often, this git alias will be helpful:

```
[alias]
pr = !sh -c \"git fetch upstream pull/${1}/head:pr/${1} && git checkout pr/${1}\"
```

Add it to your ~/.gitconfig, and set upstream to be django/django. Then you can run `git pr ####` to checkout the corresponding pull request.

At this point, you can work on the code. Use `git rebase -i` and `git commit --amend` to make sure the commits have the expected level of quality. Once you're ready:

```
$ # Pull in the latest changes from main.
$ git checkout main
$ git pull upstream main
$ # Rebase the pull request on main.
$ git checkout pr/####
$ git rebase main
```

(continues on next page)

(continued from previous page)

```
$ git checkout main
$ # Merge the work as "fast-forward" to main to avoid a merge commit.
$ # (in practice, you can omit "--ff-only" since you just rebased)
$ git merge --ff-only pr/XXXX
$ # If you're not sure if you did things correctly, check that only the
$ # changes you expect will be pushed to upstream.
$ git push --dry-run upstream main
$ # Push!
$ git push upstream main
$ # Delete the pull request branch.
$ git branch -d pr/xxxx
```

Force push to the branch after rebasing on main but before merging and pushing to upstream. This allows the commit hashes on main and the branch to match which automatically closes the pull request.

If a pull request doesn't need to be merged as multiple commits, you can use GitHub's "Squash and merge" button on the website. Edit the commit message as needed to conform to [the guidelines](#) and remove the pull request number that's automatically appended to the message's first line.

When rewriting the commit history of a pull request, the goal is to make Django's commit history as usable as possible:

- If a patch contains back-and-forth commits, then rewrite those into one. For example, if a commit adds some code and a second commit fixes stylistic issues introduced in the first commit, those commits should be squashed before merging.
- Separate changes to different commits by logical grouping: if you do a stylistic cleanup at the same time as you do other changes to a file, separating the changes into two different commits will make reviewing history easier.
- Beware of merges of upstream branches in the pull requests.
- Tests should pass and docs should build after each commit. Neither the tests nor the docs should emit warnings.
- Trivial and small patches usually are best done in one commit. Medium to large work may be split into multiple commits if it makes sense.

Practicality beats purity, so it is up to each merger to decide how much history mangling to do for a pull request. The main points are engaging the community, getting work done, and having a usable commit history.

Committing guidelines

In addition, please follow the following guidelines when committing code to Django's Git repository:

- Never change the published history of `django/django` branches by force pushing. If you absolutely must (for security reasons for example), first discuss the situation with the team.
- For any medium-to-big changes, where “medium-to-big” is according to your judgment, please bring things up on the [Django Forum](#) or [django-developers](#) mailing list before making the change.

If you bring something up and nobody responds, please don't take that to mean your idea is great and should be implemented immediately because nobody contested it. Everyone doesn't always have a lot of time to read mailing list discussions immediately, so you may have to wait a couple of days before getting a response.

- Write detailed commit messages in the past tense, not present tense.
 - Good: “Fixed Unicode bug in RSS API.”
 - Bad: “Fixes Unicode bug in RSS API.”
 - Bad: “Fixing Unicode bug in RSS API.”

The commit message should be in lines of 72 chars maximum. There should be a subject line, separated by a blank line and then paragraphs of 72 char lines. The limits are soft. For the subject line, shorter is better. In the body of the commit message more detail is better than less:

```
Fixed #18307 -- Added git workflow guidelines.
```

```
Refactored the Django's documentation to remove mentions of SVN  
specific tasks. Added guidelines of how to use Git, GitHub, and  
how to use pull request together with Trac instead.
```

Credit the contributors in the commit message: “Thanks A for the report and B for review.” Use git's [Co-Authored-By](#) as appropriate.

- For commits to a branch, prefix the commit message with the branch name. For example: “[1.4.x] Fixed #xxxxxx –Added support for mind reading.”
- Limit commits to the most granular change that makes sense. This means, use frequent small commits rather than infrequent large commits. For example, if implementing feature X requires a small change to library Y, first commit the change to library Y, then commit feature X in a separate commit. This goes a long way in helping everyone follow your changes.
- Separate bug fixes from feature changes. Bugfixes may need to be backported to the stable branch, according to [Supported versions](#).
- If your commit closes a ticket in the Django [ticket tracker](#), begin your commit message with the text “Fixed #xxxxxx” , where “xxxxxx” is the number of the ticket your commit fixes. Example: “Fixed

#123 –Added whizbang feature.” . We’ ve rigged Trac so that any commit message in that format will automatically close the referenced ticket and post a comment to it with the full commit message.

For the curious, we’ re using a [Trac plugin](#) for this.

Note: Note that the Trac integration doesn’ t know anything about pull requests. So if you try to close a pull request with the phrase “closes #400” in your commit message, GitHub will close the pull request, but the Trac plugin will not close the same numbered ticket in Trac.

- If your commit references a ticket in the Django [ticket tracker](#) but does not close the ticket, include the phrase “Refs #xxxxx” , where “xxxxx” is the number of the ticket your commit references. This will automatically post a comment to the appropriate ticket.
- Write commit messages for backports using this pattern:

```
[<Django version>] Fixed <ticket> -- <description>
```

```
Backport of <revision> from <branch>.
```

For example:

```
[1.3.x] Fixed #17028 -- Changed diveintopython.org -> diveintopython.net.
```

```
Backport of 80c0cbf1c97047daed2c5b41b296bbc56fe1d7e3 from main.
```

There’ s a [script on the wiki](#) to automate this.

If the commit fixes a regression, include this in the commit message:

```
Regression in 6ecccad711b52f9273b1acb07a57d3f806e93928.
```

(use the commit hash where the regression was introduced).

Reverting commits

Nobody’ s perfect; mistakes will be committed.

But try very hard to ensure that mistakes don’ t happen. Just because we have a reversion policy doesn’ t relax your responsibility to aim for the highest quality possible. Really: double-check your work, or have it checked by another merger before you commit it in the first place!

When a mistaken commit is discovered, please follow these guidelines:

- If possible, have the original author revert their own commit.
- Don’ t revert another author’ s changes without permission from the original author.

- Use `git revert` –this will make a reverse commit, but the original commit will still be part of the commit history.
- If the original author can't be reached (within a reasonable amount of time –a day or so) and the problem is severe –crashing bug, major test failures, etc. –then ask for objections on the [Django Forum](#) or [django-developers](#) mailing list then revert if there are none.
- If the problem is small (a feature commit after feature freeze, say), wait it out.
- If there's a disagreement between the merger and the reverter-to-be then try to work it out on the [Django Forum](#) or [django-developers](#) mailing list. If an agreement can't be reached then it should be put to a vote.
- If the commit introduced a confirmed, disclosed security vulnerability then the commit may be reverted immediately without permission from anyone.
- The release branch maintainer may back out commits to the release branch without permission if the commit breaks the release branch.
- If you mistakenly push a topic branch to `django/django`, delete it. For instance, if you did: `git push upstream feature_antigravity`, do a reverse push: `git push upstream :feature_antigravity`.

10.1.2 Join the Django community

We're passionate about helping Django users make the jump to contributing members of the community. There are several other ways you can help the Django community and others to maintain a great ecosystem to work in:

- Join the [Django forum](#). This forum is a place for discussing the Django framework and applications and projects that use it. This is also a good place to ask and answer any questions related to installing, using, or contributing to Django.
- Join the [django-users](#) mailing list and answer questions. This mailing list has a huge audience, and we really want to maintain a friendly and helpful atmosphere. If you're new to the Django community, you should read the [posting guidelines](#).
- Join the [Django Discord server](#) or the [#django IRC channel](#) on Libera.Chat to discuss and answer questions. By explaining Django to other users, you're going to learn a lot about the framework yourself.
- Blog about Django. We syndicate all the Django blogs we know about on the [community page](#); if you'd like to see your blog on that page you can [register it here](#).
- Contribute to open-source Django projects, write some documentation, or release your own code as an open-source pluggable application. The ecosystem of pluggable applications is a big strength of Django, help us build it!

We're looking forward to working with you. Welcome aboard! 🚢

10.2 Mailing lists and Forum

Important: Please report security issues only to security@djangoproject.com. This is a private list only open to long-time, highly trusted Django developers, and its archives are not public. For further details, please see [our security policies](#).

10.2.1 Django Forum

Django has an [official Forum](#) where you can input and ask questions.

There are several categories of discussion including:

- [Using Django](#): to ask any question regarding the installation, usage, or debugging of Django.
- [Internals](#): for discussion of the development of Django itself.

In addition, Django has several official mailing lists on Google Groups that are open to anyone.

10.2.2 `django-users`

Note: The [Using Django](#) category of the [official Forum](#) is now the preferred venue for asking usage questions.

This is the right place if you are looking to ask any question regarding the installation, usage, or debugging of Django.

Note: If it's the first time you send an email to this list, your email must be accepted first so don't worry if [your message does not appear](#) instantly.

- [django-users mailing archive](#)
- [django-users subscription email address](#)
- [django-users posting email](#)

10.2.3 django-developers

Note: The [Internals](#) category of the [official Forum](#) is now the preferred venue for discussing the development of Django.

The discussion about the development of Django itself takes place here.

Before asking a question about how to contribute, read [Contributing to Django](#). Many frequently asked questions are answered there.

Note: Please make use of [django-users mailing list](#) if you want to ask for tech support, doing so in this list is inappropriate.

- [django-developers mailing archive](#)
- [django-developers subscription email address](#)
- [django-developers posting email](#)

10.2.4 django-announce

A (very) low-traffic list for announcing [upcoming security releases](#), new releases of Django, and security advisories.

- [django-announce mailing archive](#)
- [django-announce subscription email address](#)
- [django-announce posting email](#)

10.2.5 django-updates

All the ticket updates are mailed automatically to this list, which is tracked by developers and interested community members.

- [django-updates mailing archive](#)
- [django-updates subscription email address](#)
- [django-updates posting email](#)

10.3 Organization of the Django Project

10.3.1 Principles

The Django Project is managed by a team of volunteers pursuing three goals:

- Driving the development of the Django web framework,
- Fostering the ecosystem of Django-related software,
- Leading the Django community in accordance with the values described in the [Django Code of Conduct](#).

The Django Project isn't a legal entity. The [Django Software Foundation](#), a non-profit organization, handles financial and legal matters related to the Django Project. Other than that, the Django Software Foundation lets the Django Project manage the development of the Django framework, its ecosystem and its community.

10.3.2 Mergers

Role

[Mergers](#) are a small set of people who merge pull requests to the [Django Git repository](#).

Prerogatives

Mergers hold the following prerogatives:

- Merging any pull request which constitutes a [minor change](#) (small enough not to require the use of the [DEP process](#)). A Merger must not merge a change primarily authored by that Merger, unless the pull request has been approved by:
 - another Merger,
 - a steering council member,
 - a member of the [triage & review team](#), or
 - a member of the [security team](#).
- Initiating discussion of a minor change in the appropriate venue, and request that other Mergers refrain from merging it while discussion proceeds.
- Requesting a vote of the steering council regarding any minor change if, in the Merger's opinion, discussion has failed to reach a consensus.
- Requesting a vote of the steering council when a [major change](#) (significant enough to require the use of the [DEP process](#)) reaches one of its implementation milestones and is intended to merge.

Membership

The steering council selects Mergers as necessary to maintain their number at a minimum of three, in order to spread the workload and avoid over-burdening or burning out any individual Merger. There is no upper limit to the number of Mergers.

It's not a requirement that a Merger is also a Django Fellow, but the Django Software Foundation has the power to use funding of Fellow positions as a way to make the role of Merger sustainable.

The following restrictions apply to the role of Merger:

- A person must not simultaneously serve as a member of the steering council. If a Merger is elected to the steering council, they shall cease to be a Merger immediately upon taking up membership in the steering council.
- A person may serve in the roles of Releaser and Merger simultaneously.

The selection process, when a vacancy occurs or when the steering council deems it necessary to select additional persons for such a role, occur as follows:

- Any member in good standing of an appropriate discussion venue, or the Django Software Foundation board acting with the input of the DSF's Fellowship committee, may suggest a person for consideration.
- The steering council considers the suggestions put forth, and then any member of the steering council formally nominates a candidate for the role.
- The steering council votes on nominees.

Mergers may resign their role at any time, but should endeavor to provide some advance notice in order to allow the selection of a replacement. Termination of the contract of a Django Fellow by the Django Software Foundation temporarily suspends that person's Merger role until such time as the steering council can vote on their nomination.

Otherwise, a Merger may be removed by:

- Becoming disqualified due to election to the steering council.
- Becoming disqualified due to actions taken by the Code of Conduct committee of the Django Software Foundation.
- A vote of the steering council.

10.3.3 Releasers

Role

Releasers are a small set of people who have the authority to upload packaged releases of Django to the [Python Package Index](#) and to the [djangoproject.com](#) website.

Prerogatives

Releasers build Django releases and upload them to the [Python Package Index](#) and to the [djangoproject.com](#) website.

Membership

The steering council selects Releasers as necessary to maintain their number at a minimum of three, in order to spread the workload and avoid over-burdening or burning out any individual Releaser. There is no upper limit to the number of Releasers.

It's not a requirement that a Releaser is also a Django Fellow, but the Django Software Foundation has the power to use funding of Fellow positions as a way to make the role of Releaser sustainable.

A person may serve in the roles of Releaser and Merger simultaneously.

The selection process, when a vacancy occurs or when the steering council deems it necessary to select additional persons for such a role, occur as follows:

- Any member in good standing of an appropriate discussion venue, or the Django Software Foundation board acting with the input of the DSF's Fellowship committee, may suggest a person for consideration.
- The steering council considers the suggestions put forth, and then any member of the steering council formally nominates a candidate for the role.
- The steering council votes on nominees.

Releasers may resign their role at any time, but should endeavor to provide some advance notice in order to allow the selection of a replacement. Termination of the contract of a Django Fellow by the Django Software Foundation temporarily suspends that person's Releaser role until such time as the steering council can vote on their nomination.

Otherwise, a Releaser may be removed by:

- Becoming disqualified due to actions taken by the Code of Conduct committee of the Django Software Foundation.
- A vote of the steering council.

10.3.4 Steering council

Role

The steering council is a group of experienced contributors who:

- provide oversight of Django’ s development and release process,
- assist in setting the direction of feature development and releases,
- take part in filling certain roles, and
- have a tie-breaking vote when other decision-making processes fail.

Their main concern is to maintain the quality and stability of the Django Web Framework.

Prerogatives

The steering council holds the following prerogatives:

- Making a binding decision regarding any question of a technical change to Django.
- Vetoing the merging of any particular piece of code into Django or ordering the reversion of any particular merge or commit.
- Announcing calls for proposals and ideas for the future technical direction of Django.
- Setting and adjusting the schedule of releases of Django.
- Selecting and removing mergers and releasers.
- Participating in the removal of members of the steering council, when deemed appropriate.
- Calling elections of the steering council outside of those which are automatically triggered, at times when the steering council deems an election is appropriate.
- Participating in modifying Django’ s governance (see [Changing the organization](#)).
- Declining to vote on a matter the steering council feels is unripe for a binding decision, or which the steering council feels is outside the scope of its powers.
- Taking charge of the governance of other technical teams within the Django open-source project, and governing those teams accordingly.

Membership

The [steering council](#) is an elected group of five experienced contributors who demonstrate:

- A history of substantive contributions to Django or the Django ecosystem. This history must begin at least 18 months prior to the individual's candidacy for the Steering Council, and include substantive contributions in at least two of these bullet points: - Code contributions on Django projects or major third-party packages in the Django ecosystem - Reviewing pull requests and/or triaging Django project tickets - Documentation, tutorials or blog posts - Discussions about Django on the [django-developers](#) mailing list or the Django Forum - Running Django-related events or user groups
- A history of engagement with the direction and future of Django. This does not need to be recent, but candidates who have not engaged in the past three years must still demonstrate an understanding of Django's changes and direction within those three years.

A new council is elected after each release cycle of Django. The election process works as follows:

1. The steering council directs one of its members to notify the Secretary of the Django Software Foundation, in writing, of the triggering of the election, and the condition which triggered it. The Secretary post to the appropriate venue –the [django-developers](#) mailing list and the [Django forum](#) to announce the election and its timeline.
2. As soon as the election is announced, the [DSF Board](#) begin a period of voter registration. All [individual members of the DSF](#) are automatically registered and need not explicitly register. All other persons who believe themselves eligible to vote, but who have not yet registered to vote, may make an application to the DSF Board for voting privileges. The voter registration form and roll of voters is maintained by the DSF Board. The DSF Board may challenge and reject the registration of voters it believes are registering in bad faith or who it believes have falsified their qualifications or are otherwise unqualified.
3. Registration of voters close one week after the announcement of the election. At that point, registration of candidates begin. Any qualified person may register as a candidate. The candidate registration form and roster of candidates are maintained by the DSF Board, and candidates must provide evidence of their qualifications as part of registration. The DSF Board may challenge and reject the registration of candidates it believes do not meet the qualifications of members of the Steering Council, or who it believes are registering in bad faith.
4. Registration of candidates close one week after it has opened. One week after registration of candidates closes, the Secretary of the DSF publish the roster of candidates to the [django-developers](#) mailing list and the [Django forum](#), and the election begin. The DSF Board provide a voting form accessible to registered voters, and is the custodian of the votes.
5. Voting is by secret ballot containing the roster of candidates, and any relevant materials regarding the candidates, in a randomized order. Each voter may vote for up to five candidates on the ballot.
6. The election conclude one week after it begins. The DSF Board then tally the votes and produce a summary, including the total number of votes cast and the number received by each candidate. This summary is ratified by a majority vote of the DSF Board, then posted by the Secretary of the DSF to

the [django-developers](#) mailing list and the Django Forum. The five candidates with the highest vote totals are immediately become the new steering council.

A member of the steering council may be removed by:

- Becoming disqualified due to actions taken by the Code of Conduct committee of the Django Software Foundation.
- Determining that they did not possess the qualifications of a member of the steering council. This determination must be made jointly by the other members of the steering council, and the [DSF Board](#). A valid determination of ineligibility requires that all other members of the steering council and all members of the DSF Board vote who can vote on the issue (the affected person, if a DSF Board member, must not vote) vote “yes” on a motion that the person in question is ineligible.

10.3.5 Changing the organization

Changes to this document require the use of the [DEP process](#), with modifications described in [DEP 0010](#).

10.4 Django’ s security policies

Django’ s development team is strongly committed to responsible reporting and disclosure of security-related issues. As such, we’ ve adopted and follow a set of policies which conform to that ideal and are geared toward allowing us to deliver timely security updates to the official distribution of Django, as well as to third-party distributions.

10.4.1 Reporting security issues

Short version: please report security issues by emailing security@djangoproject.com.

Most normal bugs in Django are reported to [our public Trac instance](#), but due to the sensitive nature of security issues, we ask that they not be publicly reported in this fashion.

Instead, if you believe you’ ve found something in Django which has security implications, please send a description of the issue via email to security@djangoproject.com. Mail sent to that address reaches the [security team](#).

Once you’ ve submitted an issue via email, you should receive an acknowledgment from a member of the security team within 48 hours, and depending on the action to be taken, you may receive further followup emails.

Sending encrypted reports

If you want to send an encrypted email (optional), the public key ID for `security@djangoproject.com` is `0x1cb84b8d1d17f80b`, and this public key is available from most commonly-used key servers.

10.4.2 Supported versions

At any given time, the Django team provides official security support for several versions of Django:

- The [main development branch](#), hosted on GitHub, which will become the next major release of Django, receives security support. Security issues that only affect the main development branch and not any stable released versions are fixed in public without going through the [disclosure process](#).
- The two most recent Django release series receive security support. For example, during the development cycle leading to the release of Django 1.5, support will be provided for Django 1.4 and Django 1.3. Upon the release of Django 1.5, Django 1.3's security support will end.
- [Long-term support releases](#) will receive security updates for a specified period.

When new releases are issued for security reasons, the accompanying notice will include a list of affected versions. This list is comprised solely of supported versions of Django: older versions may also be affected, but we do not investigate to determine that, and will not issue patches or new releases for those versions.

10.4.3 How Django discloses security issues

Our process for taking a security issue from private discussion to public disclosure involves multiple steps.

Approximately one week before public disclosure, we send two notifications:

First, we notify [django-announce](#) of the date and approximate time of the upcoming security release, as well as the severity of the issues. This is to aid organizations that need to ensure they have staff available to handle triaging our announcement and upgrade Django as needed. Severity levels are:

High:

- Remote code execution
- SQL injection

Moderate:

- Cross site scripting (XSS)
- Cross site request forgery (CSRF)
- Denial-of-service attacks
- Broken authentication

Low:

- Sensitive data exposure

- Broken session management
- Unvalidated redirects/forwards
- Issues requiring an uncommon configuration option

Second, we notify a list of [people and organizations](#), primarily composed of operating-system vendors and other distributors of Django. This email is signed with the PGP key of someone from [Django's release team](#) and consists of:

- A full description of the issue and the affected versions of Django.
- The steps we will be taking to remedy the issue.
- The patch(es), if any, that will be applied to Django.
- The date on which the Django team will apply these patches, issue new releases and publicly disclose the issue.

On the day of disclosure, we will take the following steps:

1. Apply the relevant patch(es) to Django's codebase.
2. Issue the relevant release(s), by placing new packages on the [Python Package Index](#) and on the [djangoproject.com website](#), and tagging the new release(s) in Django's git repository.
3. Post a public entry on [the official Django development blog](#), describing the issue and its resolution in detail, pointing to the relevant patches and new releases, and crediting the reporter of the issue (if the reporter wishes to be publicly identified).
4. Post a notice to the [django-announce](#) and [oss-security@lists.openwall.com](#) mailing lists that links to the blog post.

If a reported issue is believed to be particularly time-sensitive—due to a known exploit in the wild, for example—the time between advance notification and public disclosure may be shortened considerably.

Additionally, if we have reason to believe that an issue reported to us affects other frameworks or tools in the Python/web ecosystem, we may privately contact and discuss those issues with the appropriate maintainers, and coordinate our own disclosure and resolution with theirs.

The Django team also maintains an [archive of security issues disclosed in Django](#).

10.4.4 Who receives advance notification

The full list of people and organizations who receive advance notification of security issues is not and will not be made public.

We also aim to keep this list as small as effectively possible, in order to better manage the flow of confidential information prior to disclosure. As such, our notification list is not simply a list of users of Django, and being a user of Django is not sufficient reason to be placed on the notification list.

In broad terms, recipients of security notifications fall into three groups:

1. Operating-system vendors and other distributors of Django who provide a suitably-generic (i.e., not an individual's personal email address) contact address for reporting issues with their Django package, or for general security reporting. In either case, such addresses must not forward to public mailing lists or bug trackers. Addresses which forward to the private email of an individual maintainer or security-response contact are acceptable, although private security trackers or security-response groups are strongly preferred.
2. On a case-by-case basis, individual package maintainers who have demonstrated a commitment to responding to and responsibly acting on these notifications.
3. On a case-by-case basis, other entities who, in the judgment of the Django development team, need to be made aware of a pending security issue. Typically, membership in this group will consist of some of the largest and/or most likely to be severely impacted known users or distributors of Django, and will require a demonstrated ability to responsibly receive, keep confidential and act on these notifications.

Security audit and scanning entities

As a policy, we do not add these types of entities to the notification list.

10.4.5 Requesting notifications

If you believe that you, or an organization you are authorized to represent, fall into one of the groups listed above, you can ask to be added to Django's notification list by emailing security@djangoproject.com. Please use the subject line "Security notification request".

Your request must include the following information:

- Your full, real name and the name of the organization you represent, if applicable, as well as your role within that organization.
- A detailed explanation of how you or your organization fit at least one set of criteria listed above.
- A detailed explanation of why you are requesting security notifications. Again, please keep in mind that this is not simply a list for users of Django, and the overwhelming majority of users should subscribe to [django-announce](#) to receive advanced notice of when a security release will happen, without the details of the issues, rather than request detailed notifications.
- The email address you would like to have added to our notification list.
- An explanation of who will be receiving/reviewing mail sent to that address, as well as information regarding any automated actions that will be taken (i.e., filing of a confidential issue in a bug tracker).
- For individuals, the ID of a public key associated with your address which can be used to verify email received from you and encrypt email sent to you, as needed.

Once submitted, your request will be considered by the Django development team; you will receive a reply notifying you of the result of your request within 30 days.

Please also bear in mind that for any individual or organization, receiving security notifications is a privilege granted at the sole discretion of the Django development team, and that this privilege can be revoked at any time, with or without explanation.

Provide all required information

A failure to provide the required information in your initial contact will count against you when making the decision on whether or not to approve your request.

10.5 Django’s release process

10.5.1 Official releases

Since version 1.0, Django’s release numbering works as follows:

- Versions are numbered in the form `A.B` or `A.B.C`.
- `A.B` is the feature release version number. Each version will be mostly backwards compatible with the previous release. Exceptions to this rule will be listed in the release notes.
- `C` is the patch release version number, which is incremented for bugfix and security releases. These releases will be 100% backwards-compatible with the previous patch release. The only exception is when a security or data loss issue can’t be fixed without breaking backwards-compatibility. If this happens, the release notes will provide detailed upgrade instructions.
- Before a new feature release, we’ll make alpha, beta, and release candidate releases. These are of the form `A.B alpha/beta/rc N`, which means the *N*th alpha/beta/release candidate of version `A.B`.

In git, each Django release will have a tag indicating its version number, signed with the Django release key. Additionally, each release series has its own branch, called `stable/A.B.x`, and bugfix/security releases will be issued from those branches.

For more information about how the Django project issues new releases for security purposes, please see [our security policies](#).

Feature release

Feature releases (`A.B`, `A.B+1`, etc.) will happen roughly every eight months –see [release process](#) for details. These releases will contain new features, improvements to existing features, and such.

Patch release

Patch releases (`A.B.C`, `A.B.C+1`, etc.) will be issued as needed, to fix bugs and/or security issues.

These releases will be 100% compatible with the associated feature release, unless this is impossible for security reasons or to prevent data loss. So the answer to “should I upgrade to the latest patch release?” will always be “yes.”

Long-term support release

Certain feature releases will be designated as long-term support (LTS) releases. These releases will get security and data loss fixes applied for a guaranteed period of time, typically three years.

See [the download page](#) for the releases that have been designated for long-term support.

10.5.2 Release cadence

Starting with Django 2.0, version numbers will use a loose form of [semantic versioning](#) such that each version following an LTS will bump to the next “dot zero” version. For example: 2.0, 2.1, 2.2 (LTS), 3.0, 3.1, 3.2 (LTS), etc.

SemVer makes it easier to see at a glance how compatible releases are with each other. It also helps to anticipate when compatibility shims will be removed. It’s not a pure form of SemVer as each feature release will continue to have a few documented backwards incompatibilities where a deprecation path isn’t possible or not worth the cost. Also, deprecations started in an LTS release (X.2) will be dropped in a non-dot-zero release (Y.1) to accommodate our policy of keeping deprecation shims for at least two feature releases. Read on to the next section for an example.

10.5.3 Deprecation policy

A feature release may deprecate certain features from previous releases. If a feature is deprecated in feature release A.x, it will continue to work in all A.x versions (for all versions of x) but raise warnings. Deprecated features will be removed in the B.0 release, or B.1 for features deprecated in the last A.x feature release to ensure deprecations are done over at least 2 feature releases.

So, for example, if we decided to start the deprecation of a function in Django 4.2:

- Django 4.2 will contain a backwards-compatible replica of the function which will raise a `RemovedInDjango51Warning`.
- Django 5.0 (the version that follows 4.2) will still contain the backwards-compatible replica.
- Django 5.1 will remove the feature outright.

The warnings are silent by default. You can turn on display of these warnings with the `python -Wd` option.

A more generic example:

- X.0
- X.1
- X.2 LTS
- Y.0: Drop deprecation shims added in X.0 and X.1.
- Y.1: Drop deprecation shims added in X.2.

- Y.2 LTS: No deprecation shims dropped (while Y.0 is no longer supported, third-party apps need to maintain compatibility back to X.2 LTS to ease LTS to LTS upgrades).
- Z.0: Drop deprecation shims added in Y.0 and Y.1.

See also the [Deprecating a feature](#) guide.

10.5.4 Supported versions

At any moment in time, Django's developer team will support a set of releases to varying levels. See the [supported versions section](#) of the download page for the current state of support for each version.

- The current development branch `main` will get new features and bug fixes requiring non-trivial refactoring.
- Patches applied to the `main` branch must also be applied to the last feature release branch, to be released in the next patch release of that feature series, when they fix critical problems:
 - Security issues.
 - Data loss bugs.
 - Crashing bugs.
 - Major functionality bugs in new features of the latest stable release.
 - Regressions from older versions of Django introduced in the current release series.

The rule of thumb is that fixes will be backported to the last feature release for bugs that would have prevented a release in the first place (release blockers).

- Security fixes and data loss bugs will be applied to the current `main` branch, the last two feature release branches, and any other supported long-term support release branches.
- Documentation fixes generally will be more freely backported to the last release branch. That's because it's highly advantageous to have the docs for the last release be up-to-date and correct, and the risk of introducing regressions is much less of a concern.

As a concrete example, consider a moment in time halfway between the release of Django 5.1 and 5.2. At this point in time:

- Features will be added to the development `main` branch, to be released as Django 5.2.
- Critical bug fixes will be applied to the `stable/5.1.x` branch, and released as 5.1.1, 5.1.2, etc.
- Security fixes and bug fixes for data loss issues will be applied to `main` and to the `stable/5.1.x`, `stable/5.0.x`, and `stable/4.2.x` (LTS) branches. They will trigger the release of 5.1.1, 5.0.5, 4.2.8, etc.
- Documentation fixes will be applied to `main`, and, if easily backported, to the latest stable branch, 5.1.x.

10.5.5 Release process

Django uses a time-based release schedule, with feature releases every eight months or so.

After each feature release, the release manager will announce a timeline for the next feature release.

Release cycle

Each release cycle consists of three parts:

Phase one: feature proposal

The first phase of the release process will include figuring out what major features to include in the next version. This should include a good deal of preliminary work on those features –working code trumps grand design.

Major features for an upcoming release will be added to the wiki roadmap page, e.g. <https://code.djangoproject.com/wiki/Version1.11Roadmap>.

Phase two: development

The second part of the release schedule is the “heads-down” working period. Using the roadmap produced at the end of phase one, we’ll all work very hard to get everything on it done.

At the end of phase two, any unfinished features will be postponed until the next release.

Phase two will culminate with an alpha release. At this point, the `stable/A.B.x` branch will be forked from `main`.

Phase three: bugfixes

The last part of a release cycle is spent fixing bugs –no new features will be accepted during this time. We’ll try to release a beta release one month after the alpha and a release candidate one month after the beta.

The release candidate marks the string freeze, and it happens at least two weeks before the final release. After this point, new translatable strings must not be added.

During this phase, mergers will be more and more conservative with backports, to avoid introducing regressions. After the release candidate, only release blockers and documentation fixes should be backported.

In parallel to this phase, `main` can receive new features, to be released in the `A.B+1` cycle.

Bug-fix releases

After a feature release (e.g. A.B), the previous release will go into bugfix mode.

The branch for the previous feature release (e.g. `stable/A.B-1.x`) will include bugfixes. Critical bugs fixed on main must also be fixed on the bugfix branch; this means that commits need to cleanly separate bug fixes from feature additions. The developer who commits a fix to main will be responsible for also applying the fix to the current bugfix branch.

10.6 Django Deprecation Timeline

This document outlines when various pieces of Django will be removed or altered in a backward incompatible way, following their deprecation, as per the [deprecation policy](#). More details about each item can often be found in the release notes of two versions prior.

10.6.1 5.1

See the [Django 4.2 release notes](#) for more details on these changes.

- The `BaseUserManager.make_random_password()` method will be removed.
- The model's `Meta.index_together` option will be removed.
- The `length_is` template filter will be removed.
- The `django.contrib.auth.hashers.SHA1PasswordHasher`, `django.contrib.auth.hashers.UnsaltedSHA1PasswordHasher`, and `django.contrib.auth.hashers.UnsaltedMD5PasswordHasher` will be removed.
- The model `django.contrib.postgres.fields.CICharField`, `django.contrib.postgres.fields.CIEmailField`, and `django.contrib.postgres.fields.CITextField` will be removed. Stub fields will remain for compatibility with historical migrations.
- The `django.contrib.postgres.fields.CIText` mixin will be removed.
- The `map_width` and `map_height` attributes of `BaseGeometryWidget` will be removed.
- The `SimpleTestCase.assertFormsetError()` method will be removed.
- The `TransactionTestCase.assertQuerysetEqual()` method will be removed.
- Support for passing encoded JSON string literals to `JSONField` and associated lookups and expressions will be removed.
- Support for passing positional arguments to `Signer` and `TimestampSigner` will be removed.
- The `DEFAULT_FILE_STORAGE` and `STATICFILES_STORAGE` settings will be removed.
- The `django.core.files.storage.get_storage_class()` function will be removed.

10.6.2 5.0

See the [Django 4.0 release notes](#) for more details on these changes.

- The `SERIALIZE` test setting will be removed.
- The undocumented `django.utils.baseconv` module will be removed.
- The undocumented `django.utils.datetime_safe` module will be removed.
- The default value of the `USE_TZ` setting will change from `False` to `True`.
- The default sitemap protocol for sitemaps built outside the context of a request will change from `'http'` to `'https'`.
- The `extra_tests` argument for `DiscoverRunner.build_suite()` and `DiscoverRunner.run_tests()` will be removed.
- The `django.contrib.postgres.aggregates.ArrayAgg`, `JSONBAgg`, and `StringAgg` aggregates will return `None` when there are no rows instead of `[]`, `[]`, and `' '` respectively.
- The `USE_L10N` setting will be removed.
- The `USE_DEPRECATED_PYTZ` transitional setting will be removed.
- Support for `pytz` timezones will be removed.
- The `is_dst` argument will be removed from:
 - `QuerySet.dates()`
 - `django.utils.timezone.make_aware()`
 - `django.db.models.functions.Trunc()`
 - `django.db.models.functions.TruncSecond()`
 - `django.db.models.functions.TruncMinute()`
 - `django.db.models.functions.TruncHour()`
 - `django.db.models.functions.TruncDay()`
 - `django.db.models.functions.TruncWeek()`
 - `django.db.models.functions.TruncMonth()`
 - `django.db.models.functions.TruncQuarter()`
 - `django.db.models.functions.TruncYear()`
- The `django.contrib.gis.admin.GeoModelAdmin` and `OSMGeoAdmin` classes will be removed.
- The undocumented `BaseForm._html_output()` method will be removed.
- The ability to return a `str`, rather than a `SafeString`, when rendering an `ErrorDict` and `ErrorList` will be removed.

See the [Django 4.1 release notes](#) for more details on these changes.

- The `SitemapIndexItem.__str__()` method will be removed.
- The `CSRF_COOKIE_MASKED` transitional setting will be removed.
- The `name` argument of `django.utils.functional.cached_property()` will be removed.
- The `opclasses` argument of `django.contrib.postgres.constraints.ExclusionConstraint` will be removed.
- The undocumented ability to pass `errors=None` to `SimpleTestCase.assertFormError()` and `assertFormsetError()` will be removed.
- `django.contrib.sessions.serializers.PickleSerializer` will be removed.
- The usage of `QuerySet.iterator()` on a queryset that prefetches related objects without providing the `chunk_size` argument will no longer be allowed.
- Passing unsaved model instances to related filters will no longer be allowed.
- `created=True` will be required in the signature of `RemoteUserBackend.configure_user()` subclasses.
- Support for logging out via GET requests in the `django.contrib.auth.views.LogoutView` and `django.contrib.auth.views.logout_then_login()` will be removed.
- The `django.utils.timezone.utc` alias to `datetime.timezone.utc` will be removed.
- Passing a response object and a form/formset name to `SimpleTestCase.assertFormError()` and `assertFormsetError()` will no longer be allowed.
- The `django.contrib.gis.admin.OpenLayersWidget` will be removed.
- The `django.contrib.auth.hashers.CryptPasswordHasher` will be removed.
- The `"django/forms/default.html"` and `"django/forms/formsets/default.html"` templates will be removed.
- The ability to pass `nulls_first=False` or `nulls_last=False` to `Expression.asc()` and `Expression.desc()` methods, and the `OrderBy` expression will be removed.

10.6.3 4.1

See the [Django 3.2 release notes](#) for more details on these changes.

- Support for assigning objects which don't support creating deep copies with `copy.deepcopy()` to class attributes in `TestCase.setUpTestData()` will be removed.
- `BaseCommand.requires_system_checks` won't support boolean values.
- The `whitelist` argument and `domain_whitelist` attribute of `django.core.validators.EmailValidator` will be removed.
- The `default_app_config` module variable will be removed.

- `TransactionTestCase.assertQuerysetEqual()` will no longer automatically call `repr()` on a query-set when compared to string values.
- `django.core.cache.backends.memcached.MemcachedCache` will be removed.
- Support for the pre-Django 3.2 format of messages used by `django.contrib.messages.storage.cookie.CookieStorage` will be removed.

10.6.4 4.0

See the [Django 3.0 release notes](#) for more details on these changes.

- `django.utils.http.urlquote()`, `urlquote_plus()`, `urlunquote()`, and `urlunquote_plus()` will be removed.
- `django.utils.encoding.force_text()` and `smart_text()` will be removed.
- `django.utils.translation.ugettext()`, `ugettext_lazy()`, `ugettext_noop()`, `ungettext()`, and `ungettext_lazy()` will be removed.
- `django.views.i18n.set_language()` will no longer set the user language in `request.session` (key `django.utils.translation.LANGUAGE_SESSION_KEY`).
- `alias=None` will be required in the signature of `django.db.models.Expression.get_group_by_cols()` subclasses.
- `django.utils.text.unescape_entities()` will be removed.
- `django.utils.http.is_safe_url()` will be removed.

See the [Django 3.1 release notes](#) for more details on these changes.

- The `PASSWORD_RESET_TIMEOUT_DAYS` setting will be removed.
- The undocumented usage of the *isnull* lookup with non-boolean values as the right-hand side will no longer be allowed.
- The `django.db.models.query_utils.InvalidQuery` exception class will be removed.
- The `django-admin.py` entry point will be removed.
- The `HttpRequest.is_ajax()` method will be removed.
- Support for the pre-Django 3.1 encoding format of cookies values used by `django.contrib.messages.storage.cookie.CookieStorage` will be removed.
- Support for the pre-Django 3.1 password reset tokens in the admin site (that use the SHA-1 hashing algorithm) will be removed.
- Support for the pre-Django 3.1 encoding format of sessions will be removed.
- Support for the pre-Django 3.1 `django.core.signing.Signer` signatures (encoded with the SHA-1 algorithm) will be removed.

- Support for the pre-Django 3.1 `django.core.signing.dumps()` signatures (encoded with the SHA-1 algorithm) in `django.core.signing.loads()` will be removed.
- Support for the pre-Django 3.1 user sessions (that use the SHA-1 algorithm) will be removed.
- The `get_response` argument for `django.utils.deprecation.MiddlewareMixin.__init__()` will be required and won't accept `None`.
- The `providing_args` argument for `django.dispatch.Signal` will be removed.
- The `length` argument for `django.utils.crypto.get_random_string()` will be required.
- The `list` message for `ModelMultipleChoiceField` will be removed.
- Support for passing raw column aliases to `QuerySet.order_by()` will be removed.
- The model `NullBooleanField` will be removed. A stub field will remain for compatibility with historical migrations.
- `django.conf.urls.url()` will be removed.
- The model `django.contrib.postgres.fields.JSONField` will be removed. A stub field will remain for compatibility with historical migrations.
- `django.contrib.postgres.forms.JSONField`, `django.contrib.postgres.fields.jsonb.KeyTransform`, and `django.contrib.postgres.fields.jsonb.KeyTextTransform` will be removed.
- The `{% ifequal %}` and `{% ifnotequal %}` template tags will be removed.
- The `DEFAULT_HASHING_ALGORITHM` transitional setting will be removed.

10.6.5 3.1

See the [Django 2.2 release notes](#) for more details on these changes.

- `django.utils.timezone.FixedOffset` will be removed.
- `django.core.paginator.QuerySetPaginator` will be removed.
- A model's `Meta.ordering` will no longer affect `GROUP BY` queries.
- `django.contrib.postgres.fields.FloatRangeField` and `django.contrib.postgres.forms.FloatRangeField` will be removed.
- The `FILE_CHARSET` setting will be removed.
- `django.contrib.staticfiles.storage.CachedStaticFilesStorage` will be removed.
- `RemoteUserBackend.configure_user()` will require `request` as the first positional argument.
- Support for `SimpleTestCase.allow_database_queries` and `TransactionTestCase.multi_db` will be removed.

10.6.6 3.0

See the [Django 2.0 release notes](#) for more details on these changes.

- The `django.db.backends.postgresql_psycopg2` module will be removed.
- `django.shortcuts.render_to_response()` will be removed.
- The `DEFAULT_CONTENT_TYPE` setting will be removed.
- `HttpRequest.xreadlines()` will be removed.
- Support for the `context` argument of `Field.from_db_value()` and `Expression.convert_value()` will be removed.
- The `field_name` keyword argument of `QuerySet.earliest()` and `latest()` will be removed.

See the [Django 2.1 release notes](#) for more details on these changes.

- `django.contrib.gis.db.models.functions.ForceRHR` will be removed.
- `django.utils.http.cookie_date()` will be removed.
- The `staticfiles` and `admin_static` template tag libraries will be removed.
- `django.contrib.staticfiles.templatetags.static()` will be removed.
- The shim to allow `InlineModelAdmin.has_add_permission()` to be defined without an `obj` argument will be removed.

10.6.7 2.1

See the [Django 1.11 release notes](#) for more details on these changes.

- `contrib.auth.views.login()`, `logout()`, `password_change()`, `password_change_done()`, `password_reset()`, `password_reset_done()`, `password_reset_confirm()`, and `password_reset_complete()` will be removed.
- The `extra_context` parameter of `contrib.auth.views.logout_then_login()` will be removed.
- `django.test.runner.setup_databases()` will be removed.
- `django.utils.translation.string_concat()` will be removed.
- `django.core.cache.backends.memcached.PyLibMCCache` will no longer support passing `pylibmc` behavior settings as top-level attributes of `OPTIONS`.
- The `host` parameter of `django.utils.http.is_safe_url()` will be removed.
- Silencing of exceptions raised while rendering the `{% include %}` template tag will be removed.
- `DatabaseIntrospection.get_indexes()` will be removed.

- The `authenticate()` method of authentication backends will require `request` as the first positional argument.
- The `django.db.models.permlink()` decorator will be removed.
- The `USE_ETAGS` setting will be removed. `CommonMiddleware` and `django.utils.cache.patch_response_headers()` will no longer set ETags.
- The `Model._meta.has_auto_field` attribute will be removed.
- `url()`'s support for inline flags in regular expression groups `((?i)`, `(?L)`, `(?m)`, `(?s)`, and `(?u))` will be removed.
- Support for `Widget.render()` methods without the `renderer` argument will be removed.

10.6.8 2.0

See the [Django 1.9 release notes](#) for more details on these changes.

- The `weak` argument to `django.dispatch.signals.Signal.disconnect()` will be removed.
- `django.db.backends.base.BaseDatabaseOperations.check_aggregate_support()` will be removed.
- The `django.forms.extras` package will be removed.
- The `assignment_tag` helper will be removed.
- The `host` argument to `assertsRedirects` will be removed. The compatibility layer which allows absolute URLs to be considered equal to relative ones when the path is identical will also be removed.
- `Field.rel` will be removed.
- `Field.remote_field.to` attribute will be removed.
- The `on_delete` argument for `ForeignKey` and `OneToOneField` will be required.
- `django.db.models.fields.add_lazy_relation()` will be removed.
- When time zone support is enabled, database backends that don't support time zones won't convert aware datetimes to naive values in UTC anymore when such values are passed as parameters to SQL queries executed outside of the ORM, e.g. with `cursor.execute()`.
- The `django.contrib.auth.tests.utils.skipIfCustomUser()` decorator will be removed.
- The `GeoManager` and `GeoQuerySet` classes will be removed.
- The `django.contrib.gis.geoip` module will be removed.
- The `supports_recursion` check for template loaders will be removed from:
 - `django.template.engine.Engine.find_template()`
 - `django.template.loader_tags.ExtendsNode.find_template()`

- `django.template.loaders.base.Loader.supports_recursion()`
 - `django.template.loaders.cached.Loader.supports_recursion()`
- The `load_template()` and `load_template_sources()` template loader methods will be removed.
- The `template_dirs` argument for template loaders will be removed:
 - `django.template.loaders.base.Loader.get_template()`
 - `django.template.loaders.cached.Loader.cache_key()`
 - `django.template.loaders.cached.Loader.get_template()`
 - `django.template.loaders.cached.Loader.get_template_sources()`
 - `django.template.loaders.filesystem.Loader.get_template_sources()`
- The `django.template.loaders.base.Loader.__call__()` method will be removed.
- Support for custom error views with a single positional parameter will be dropped.
- The `mime_type` attribute of `django.utils.feedgenerator.Atom1Feed` and `django.utils.feedgenerator.RssFeed` will be removed in favor of `content_type`.
- The `app_name` argument to `django.conf.urls.include()` will be removed.
- Support for passing a 3-tuple as the first argument to `include()` will be removed.
- Support for setting a URL instance namespace without an application namespace will be removed.
- `Field._get_val_from_obj()` will be removed in favor of `Field.value_from_object()`.
- `django.template.loaders.eggs.Loader` will be removed.
- The `current_app` parameter to the `contrib.auth` views will be removed.
- The `callable_obj` keyword argument to `SimpleTestCase.assertRaisesMessage()` will be removed.
- Support for the `allow_tags` attribute on `ModelAdmin` methods will be removed.
- The `enclosure` keyword argument to `SyndicationFeed.add_item()` will be removed.
- The `django.template.loader.LoaderOrigin` and `django.template.base.StringOrigin` aliases for `django.template.base.Origin` will be removed.

See the [Django 1.10 release notes](#) for more details on these changes.

- The `makemigrations --exit` option will be removed.
- Support for direct assignment to a reverse foreign key or many-to-many relation will be removed.
- The `get_srid()` and `set_srid()` methods of `django.contrib.gis.geos.GEOSGeometry` will be removed.
- The `get_x()`, `set_x()`, `get_y()`, `set_y()`, `get_z()`, and `set_z()` methods of `django.contrib.gis.geos.Point` will be removed.

- The `get_coords()` and `set_coords()` methods of `django.contrib.gis.geos.Point` will be removed.
- The `cascaded_union` property of `django.contrib.gis.geos.MultiPolygon` will be removed.
- `django.utils.functional.allow_lazy()` will be removed.
- The `shell --plain` option will be removed.
- The `django.core.urlresolvers` module will be removed.
- The model `CommaSeparatedIntegerField` will be removed. A stub field will remain for compatibility with historical migrations.
- Support for the template `Context.has_key()` method will be removed.
- Support for the `django.core.files.storage.Storage.accessed_time()`, `created_time()`, and `modified_time()` methods will be removed.
- Support for query lookups using the model name when `Meta.default_related_name` is set will be removed.
- The `__search` query lookup and the `DatabaseOperations.fulltext_search_sql()` method will be removed.
- The shim for supporting custom related manager classes without a `_apply_rel_filters()` method will be removed.
- Using `User.is_authenticated()` and `User.is_anonymous()` as methods will no longer be supported.
- The private attribute `virtual_fields` of `Model._meta` will be removed.
- The private keyword arguments `virtual_only` in `Field.contribute_to_class()` and `virtual` in `Model._meta.add_field()` will be removed.
- The `javascript_catalog()` and `json_catalog()` views will be removed.
- The `django.contrib.gis.utils.precision_wkt()` function will be removed.
- In multi-table inheritance, implicit promotion of a `OneToOneField` to a `parent_link` will be removed.
- Support for `Widget._format_value()` will be removed.
- `FileField` methods `get_directory_name()` and `get_filename()` will be removed.
- The `mark_for_escaping()` function and the classes it uses: `EscapeData`, `EscapeBytes`, `EscapeText`, `EscapeString`, and `EscapeUnicode` will be removed.
- The escape filter will change to use `django.utils.html.conditional_escape()`.
- `Manager.use_for_related_fields` will be removed.
- Model Manager inheritance will follow MRO inheritance rules and the `Meta.manager_inheritance_from_future` to opt-in to this behavior will be removed.
- Support for old-style middleware using `settings.MIDDLEWARE_CLASSES` will be removed.

10.6.9 1.10

See the [Django 1.8 release notes](#) for more details on these changes.

- Support for calling a `SQLCompiler` directly as an alias for calling its `quote_name_unless_alias` method will be removed.
- `cycle` and `firstof` template tags will be removed from the future template tag library (used during the 1.6/1.7 deprecation period).
- `django.conf.urls.patterns()` will be removed.
- Support for the `prefix` argument to `django.conf.urls.i18n.i18n_patterns()` will be removed.
- `SimpleTestCase.urls` will be removed.
- Using an incorrect count of unpacked values in the `for` template tag will raise an exception rather than fail silently.
- The ability to reverse URLs using a dotted Python path will be removed.
- The ability to use a dotted Python path for the `LOGIN_URL` and `LOGIN_REDIRECT_URL` settings will be removed.
- Support for `optparse` will be dropped for custom management commands (replaced by `argparse`).
- The class `django.core.management.NoArgsCommand` will be removed. Use `BaseCommand` instead, which takes no arguments by default.
- `django.core.context_processors` module will be removed.
- `django.db.models.sql.aggregates` module will be removed.
- `django.contrib.gis.db.models.sql.aggregates` module will be removed.
- The following methods and properties of `django.db.sql.query.Query` will be removed:
 - Properties: `aggregates` and `aggregate_select`
 - Methods: `add_aggregate`, `set_aggregate_mask`, and `append_aggregate_mask`.
- `django.template.resolve_variable` will be removed.
- The following private APIs will be removed from `django.db.models.options.Options` (`Model._meta`):
 - `get_field_by_name()`
 - `get_all_field_names()`
 - `get_fields_with_model()`
 - `get_concrete_fields_with_model()`
 - `get_m2m_with_model()`

- `get_all_related_objects()`
 - `get_all_related_objects_with_model()`
 - `get_all_related_many_to_many_objects()`
 - `get_all_related_m2m_objects_with_model()`
- The `error_message` argument of `django.forms.RegexField` will be removed.
- The `unordered_list` filter will no longer support old style lists.
- Support for string view arguments to `url()` will be removed.
- The backward compatible shim to rename `django.forms.Form._has_changed()` to `has_changed()` will be removed.
- The `removetags` template filter will be removed.
- The `remove_tags()` and `strip_entities()` functions in `django.utils.html` will be removed.
- The `is_admin_site` argument to `django.contrib.auth.views.password_reset()` will be removed.
- `django.db.models.field.subclassing.SubfieldBase` will be removed.
- `django.utils.checksums` will be removed; its functionality is included in `django-localflavor 1.1+`.
- The `original_content_type_id` attribute on `django.contrib.admin.helpers.InlineAdminForm` will be removed.
- The backwards compatibility shim to allow `FormMixin.get_form()` to be defined with no default value for its `form_class` argument will be removed.
- The following settings will be removed:
 - `ALLOWED_INCLUDE_ROOTS`
 - `TEMPLATE_CONTEXT_PROCESSORS`
 - `TEMPLATE_DEBUG`
 - `TEMPLATE_DIRS`
 - `TEMPLATE_LOADERS`
 - `TEMPLATE_STRING_IF_INVALID`
- The backwards compatibility alias `django.template.loader.BaseLoader` will be removed.
- Django template objects returned by `get_template()` and `select_template()` won't accept a `Context` in their `render()` method anymore.
- Template response APIs will enforce the use of `dict` and backend-dependent template objects instead of `Context` and `Template` respectively.
- The `current_app` parameter for the following function and classes will be removed:
 - `django.shortcuts.render()`

- `django.template.Context()`
- `django.template.RequestContext()`
- `django.template.response.TemplateResponse()`
- The dictionary and `context_instance` parameters for the following functions will be removed:
 - `django.shortcuts.render()`
 - `django.shortcuts.render_to_response()`
 - `django.template.loader.render_to_string()`
- The `dirs` parameter for the following functions will be removed:
 - `django.template.loader.get_template()`
 - `django.template.loader.select_template()`
 - `django.shortcuts.render()`
 - `django.shortcuts.render_to_response()`
- Session verification will be enabled regardless of whether or not `'django.contrib.auth.middleware.SessionAuthenticationMiddleware'` is in `MIDDLEWARE_CLASSES`.
- Private attribute `django.db.models.Field.related` will be removed.
- The `--list` option of the migrate management command will be removed.
- The `ssi` template tag will be removed.
- Support for the `=` comparison operator in the `if` template tag will be removed.
- The backwards compatibility shims to allow `Storage.get_available_name()` and `Storage.save()` to be defined without a `max_length` argument will be removed.
- Support for the legacy `%(<foo>)s` syntax in `ModelFormMixin.success_url` will be removed.
- `GeoQuerySet` aggregate methods `collect()`, `extent()`, `extent3d()`, `make_line()`, and `unionagg()` will be removed.
- Ability to specify `ContentType.name` when creating a content type instance will be removed.
- Support for the old signature of `allow_migrate` will be removed. It changed from `allow_migrate(self, db, model)` to `allow_migrate(self, db, app_label, model_name=None, **hints)`.
- Support for the syntax of `{% cycle %}` that uses comma-separated arguments will be removed.
- The warning that *Signer* issues when given an invalid separator will become an exception.

10.6.10 1.9

See the [Django 1.7 release notes](#) for more details on these changes.

- `django.utils.dictconfig` will be removed.
- `django.utils.importlib` will be removed.
- `django.utils.tzinfo` will be removed.
- `django.utils.unittest` will be removed.
- The `syncdb` command will be removed.
- `django.db.models.signals.pre_syncdb` and `django.db.models.signals.post_syncdb` will be removed.
- `allow_syncdb` on database routers will no longer automatically become `allow_migrate`.
- Automatic syncing of apps without migrations will be removed. Migrations will become compulsory for all apps unless you pass the `--run-syncdb` option to `migrate`.
- The SQL management commands for apps without migrations, `sql`, `sqlall`, `sqlclear`, `sqldropindexes`, and `sqlindexes`, will be removed.
- Support for automatic loading of `initial_data` fixtures and initial SQL data will be removed.
- All models will need to be defined inside an installed application or declare an explicit `app_label`. Furthermore, it won't be possible to import them before their application is loaded. In particular, it won't be possible to import models inside the root package of their application.
- The model and form `IPAddressField` will be removed. A stub field will remain for compatibility with historical migrations.
- `AppCommand.handle_app()` will no longer be supported.
- `RequestSite` and `get_current_site()` will no longer be importable from `django.contrib.sites.models`.
- FastCGI support via the `runfcgi` management command will be removed. Please deploy your project using WSGI.
- `django.utils.datastructures.SortedDict` will be removed. Use `collections.OrderedDict` from the Python standard library instead.
- `ModelAdmin.declared_fieldsets` will be removed.
- Instances of `util.py` in the Django codebase have been renamed to `utils.py` in an effort to unify all `util` and `utils` references. The modules that provided backwards compatibility will be removed:
 - `django.contrib.admin.util`
 - `django.contrib.gis.db.backends.util`

- `django.db.backends.util`
- `django.forms.util`
- `ModelAdmin.get_formsets` will be removed.
- The backward compatibility shim introduced to rename the `BaseMemcachedCache._get_memcache_timeout()` method to `get_backend_timeout()` will be removed.
- The `--natural` and `-n` options for *dumpdata* will be removed.
- The `use_natural_keys` argument for `serializers.serialize()` will be removed.
- Private API `django.forms.forms.get_declared_fields()` will be removed.
- The ability to use a `SplitDateTimeWidget` with `DateTimeField` will be removed.
- The `WSGIRequest.REQUEST` property will be removed.
- The class `django.utils.datastructures.MergeDict` will be removed.
- The `zh-cn` and `zh-tw` language codes will be removed and have been replaced by the `zh-hans` and `zh-hant` language code respectively.
- The internal `django.utils.functional.memoize` will be removed.
- `django.core.cache.get_cache` will be removed. Add suitable entries to *CACHES* and use *django.core.cache.caches* instead.
- `django.db.models.loading` will be removed.
- Passing callable arguments to queriesets will no longer be possible.
- `BaseCommand.requires_model_validation` will be removed in favor of `requires_system_checks`. Admin validators will be replaced by admin checks.
- The `ModelAdmin.validator_class` and `default_validator_class` attributes will be removed.
- `ModelAdmin.validate()` will be removed.
- `django.db.backends.DatabaseValidation.validate_field` will be removed in favor of the `check_field` method.
- The `validate` management command will be removed.
- `django.utils.module_loading.import_by_path` will be removed in favor of `django.utils.module_loading.import_string`.
- `ssi` and `url` template tags will be removed from the `future` template tag library (used during the 1.3/1.4 deprecation period).
- `django.utils.text.javascript_quote` will be removed.
- Database test settings as independent entries in the database settings, prefixed by `TEST_`, will no longer be supported.

- The `cache_choices` option to *ModelChoiceField* and *ModelMultipleChoiceField* will be removed.
- The default value of the *RedirectView*.*permanent* attribute will change from `True` to `False`.
- `django.contrib.sitemaps.FlatPageSitemap` will be removed in favor of `django.contrib.flatpages.sitemaps.FlatPageSitemap`.
- Private API `django.test.utils.TestTemplateLoader` will be removed.
- The `django.contrib.contenttypes.generic` module will be removed.
- Private APIs `django.db.models.sql.where.WhereNode.make_atom()` and `django.db.models.sql.where.Constraint` will be removed.

10.6.11 1.8

See the [Django 1.6 release notes](#) for more details on these changes.

- `django.contrib.comments` will be removed.
- The following transaction management APIs will be removed:
 - `TransactionMiddleware`,
 - the decorators and context managers `autocommit`, `commit_on_success`, and `commit_manually`, defined in `django.db.transaction`,
 - the functions `commit_unless_managed` and `rollback_unless_managed`, also defined in `django.db.transaction`,
 - the `TRANSACTIONS_MANAGED` setting.
- The *cycle* and *firstof* template tags will auto-escape their arguments. In 1.6 and 1.7, this behavior is provided by the version of these tags in the future template tag library.
- The `SEND_BROKEN_LINK_EMAILS` setting will be removed. Add the *django.middleware.common.BrokenLinkEmailsMiddleware* middleware to your `MIDDLEWARE_CLASSES` setting instead.
- `django.middleware.doc.XViewMiddleware` will be removed. Use `django.contrib.admindocs.middleware.XViewMiddleware` instead.
- `Model._meta.module_name` was renamed to `model_name`.
- Remove the backward compatible shims introduced to rename `get_query_set` and similar `queryset` methods. This affects the following classes: `BaseModelAdmin`, `ChangeList`, `BaseCommentNode`, `GenericForeignKey`, `Manager`, `SingleRelatedObjectDescriptor` and `ReverseSingleRelatedObjectDescriptor`.
- Remove the backward compatible shims introduced to rename the attributes `ChangeList.root_query_set` and `ChangeList.query_set`.

- `django.views.defaults.shortcut` will be removed, as part of the goal of removing all `django.contrib` references from the core Django codebase. Instead use `django.contrib.contenttypes.views.shortcut`. `django.conf.urls.shortcut` will also be removed.
- Support for the Python Imaging Library (PIL) module will be removed, as it no longer appears to be actively maintained & does not work on Python 3.
- The following private APIs will be removed:
 - `django.db.backend`
 - `django.db.close_connection()`
 - `django.db.backends.creation.BaseDatabaseCreation.set_autocommit()`
 - `django.db.transaction.is_managed()`
 - `django.db.transaction.managed()`
- `django.forms.widgets.RadioInput` will be removed in favor of `django.forms.widgets.RadioChoiceInput`.
- The module `django.test.simple` and the class `django.test.simple.DjangoTestSuiteRunner` will be removed. Instead use `django.test.runner.DiscoverRunner`.
- The module `django.test._doctest` will be removed. Instead use the `doctest` module from the Python standard library.
- The `CACHE_MIDDLEWARE_ANONYMOUS_ONLY` setting will be removed.
- Usage of the hard-coded Hold down “Control” , or “Command” on a Mac, to select more than one string to override or append to user-provided `help_text` in forms for ManyToMany model fields will not be performed by Django anymore either at the model or forms layer.
- The `Model._meta.get_(add|change|delete)_permission` methods will be removed.
- The session key `django_language` will no longer be read for backwards compatibility.
- Geographic Sitemaps will be removed (`django.contrib.gis.sitemaps.views.index` and `django.contrib.gis.sitemaps.views.sitemap`).
- `django.utils.html.fix_ampersands`, the `fix_ampersands` template filter and `django.utils.html.clean_html` will be removed following an accelerated deprecation.

10.6.12 1.7

See the [Django 1.5 release notes](#) for more details on these changes.

- The module `django.utils.simplejson` will be removed. The standard library provides `json` which should be used instead.
- The function `django.utils.itercompat.product` will be removed. The Python builtin version should be used instead.
- Auto-correction of `INSTALLED_APPS` and `TEMPLATE_DIRS` settings when they are specified as a plain string instead of a tuple will be removed and raise an exception.
- The `mimetype` argument to the `__init__` methods of *HttpResponse*, *SimpleTemplateResponse*, and *TemplateResponse*, will be removed. `content_type` should be used instead. This also applies to the `render_to_response()` shortcut and the sitemap views, *index()* and *sitemap()*.
- When *HttpResponse* is instantiated with an iterator, or when `content` is set to an iterator, that iterator will be immediately consumed.
- The `AUTH_PROFILE_MODULE` setting, and the `get_profile()` method on the User model, will be removed.
- The `cleanup` management command will be removed. It's replaced by `clearsessions`.
- The `daily_cleanup.py` script will be removed.
- The `depth` keyword argument will be removed from *select_related()*.
- The undocumented `get_warnings_state()/restore_warnings_state()` functions from *django.test.utils* and the `save_warnings_state()/restore_warnings_state()` *django.test.TestCase* methods are deprecated. Use the `warnings.catch_warnings` context manager available starting with Python 2.6 instead.
- The undocumented `check_for_test_cookie` method in *AuthenticationForm* will be removed following an accelerated deprecation. Users subclassing this form should remove calls to this method, and instead ensure that their auth related views are CSRF protected, which ensures that cookies are enabled.
- The version of `django.contrib.auth.views.password_reset_confirm()` that supports base36 encoded user IDs (`django.contrib.auth.views.password_reset_confirm_uidb36`) will be removed. If your site has been running Django 1.6 for more than `PASSWORD_RESET_TIMEOUT_DAYS`, this change will have no effect. If not, then any password reset links generated before you upgrade to Django 1.7 won't work after the upgrade.
- The `django.utils.encoding.StrAndUnicode` mix-in will be removed.

10.6.13 1.6

See the [Django 1.4 release notes](#) for more details on these changes.

- `django.contrib.databrowse` will be removed.
- `django.contrib.localflavor` will be removed following an accelerated deprecation.
- `django.contrib.markup` will be removed following an accelerated deprecation.
- The compatibility modules `django.utils.copycompat` and `django.utils.hashcompat` as well as the functions `django.utils.itercompat.all` and `django.utils.itercompat.any` will be removed. The Python builtin versions should be used instead.
- The `csrf_response_exempt` and `csrf_view_exempt` decorators will be removed. Since 1.4 `csrf_response_exempt` has been a no-op (it returns the same function), and `csrf_view_exempt` has been a synonym for `django.views.decorators.csrf.csrf_exempt`, which should be used to replace it.
- The `django.core.cache.backends.memcached.CacheClass` backend was split into two in Django 1.3 in order to introduce support for PyLibMC. The historical `CacheClass` will be removed in favor of `django.core.cache.backends.memcached.MemcachedCache`.
- The UK-prefixed objects of `django.contrib.localflavor.uk` will only be accessible through their GB-prefixed names (GB is the correct ISO 3166 code for United Kingdom).
- The `IGNORABLE_404_STARTS` and `IGNORABLE_404_ENDS` settings have been superseded by `IGNORABLE_404_URLS` in the 1.4 release. They will be removed.
- The form wizard has been refactored to use class-based views with pluggable backends in 1.4. The previous implementation will be removed.
- Legacy ways of calling `cache_page()` will be removed.
- The backward-compatibility shim to automatically add a debug-false filter to the 'mail_admins' logging handler will be removed. The `LOGGING` setting should include this filter explicitly if it is desired.
- The builtin truncation functions `django.utils.text.truncate_words()` and `django.utils.text.truncate_html_words()` will be removed in favor of the `django.utils.text.Truncator` class.
- The `django.contrib.gis.geoip.GeoIP` class was moved to `django.contrib.gis.geoip` in 1.4 –the shortcut in `django.contrib.gis.utils` will be removed.
- `django.conf.urls.defaults` will be removed. The functions `include()`, `patterns()`, and `url()`, plus `handler404` and `handler500` are now available through `django.conf.urls`.
- The functions `setup_environ()` and `execute_manager()` will be removed from `django.core.management`. This also means that the old (pre-1.4) style of `manage.py` file will no longer work.
- Setting the `is_safe` and `needs_autoescape` flags as attributes of template filter functions will no longer be supported.

- The attribute `HttpRequest.raw_post_data` was renamed to `HttpRequest.body` in 1.4. The backward compatibility will be removed – `HttpRequest.raw_post_data` will no longer work.
- The value for the `post_url_continue` parameter in `ModelAdmin.response_add()` will have to be either `None` (to redirect to the newly created object's edit page) or a pre-formatted url. String formats, such as the previous default `'../%s/'`, will not be accepted any more.

10.6.14 1.5

See the [Django 1.3 release notes](#) for more details on these changes.

- Starting Django without a `SECRET_KEY` will result in an exception rather than a `DeprecationWarning`. (This is accelerated from the usual deprecation path; see the [Django 1.4 release notes](#).)
- The `mod_python` request handler will be removed. The `mod_wsgi` handler should be used instead.
- The `template` attribute on `django.test.client.Response` objects returned by the `test client` will be removed. The `templates` attribute should be used instead.
- The `django.test.simple.DjangoTestRunner` will be removed. Instead use a `unittest`-native class. The features of the `django.test.simple.DjangoTestRunner` (including fail-fast and Ctrl-C test termination) can be provided by `unittest.TextTestRunner`.
- The undocumented function `django.contrib.formtools.utils.security_hash` will be removed, instead use `django.contrib.formtools.utils.form_hmac`.
- The function-based generic view modules will be removed in favor of their class-based equivalents, outlined [here](#).
- The `django.core.servers.basehttp.AdminMediaHandler` will be removed. In its place use `django.contrib.staticfiles.handlers.StaticFilesHandler`.
- The template tags library `adminmedia` and the template tag `{% admin_media_prefix %}` will be removed in favor of the generic static files handling. (This is faster than the usual deprecation path; see the [Django 1.4 release notes](#).)
- The `url` and `ssi` template tags will be modified so that the first argument to each tag is a template variable, not an implied string. In 1.4, this behavior is provided by a version of the tag in the `future` template tag library.
- The `reset` and `sqlreset` management commands will be removed.
- Authentication backends will need to support an inactive user being passed to all methods dealing with permissions. The `supports_inactive_user` attribute will no longer be checked and can be removed from custom backends.
- `transform()` will raise a `GEOSException` when called on a geometry with no SRID value.
- `django.http.CompatCookie` will be removed in favor of `django.http.SimpleCookie`.

- `django.core.context_processors.PermWrapper` and `django.core.context_processors.PermLookupDict` will be removed in favor of the corresponding `django.contrib.auth.context_processors.PermWrapper` and `django.contrib.auth.context_processors.PermLookupDict`, respectively.
- The `MEDIA_URL` or `STATIC_URL` settings will be required to end with a trailing slash to ensure there is a consistent way to combine paths in templates.
- `django.db.models.fields.URLField.verify_exists` will be removed. The feature was deprecated in 1.3.1 due to intractable security and performance issues and will follow a slightly accelerated deprecation timeframe.
- Translations located under the so-called project path will be ignored during the translation building process performed at runtime. The `LOCALE_PATHS` setting can be used for the same task by including the filesystem path to a locale directory containing non-app-specific translations in its value.
- The Markup contrib app will no longer support versions of Python-Markdown library earlier than 2.1. An accelerated timeline was used as this was a security related deprecation.
- The `CACHE_BACKEND` setting will be removed. The cache backend(s) should be specified in the `CACHES` setting.

10.6.15 1.4

See the [Django 1.2 release notes](#) for more details on these changes.

- `CsrfResponseMiddleware` and `CsrfMiddleware` will be removed. Use the `{% csrf_token %}` template tag inside forms to enable CSRF protection. `CsrfViewMiddleware` remains and is enabled by default.
- The old imports for CSRF functionality (`django.contrib.csrf.*`), which moved to core in 1.2, will be removed.
- The `django.contrib.gis.db.backend` module will be removed in favor of the specific backends.
- `SMTPConnection` will be removed in favor of a generic email backend API.
- The many to many SQL generation functions on the database backends will be removed.
- The ability to use the `DATABASE_*` family of top-level settings to define database connections will be removed.
- The ability to use shorthand notation to specify a database backend (i.e., `sqlite3` instead of `django.db.backends.sqlite3`) will be removed.
- The `get_db_prep_save`, `get_db_prep_value` and `get_db_prep_lookup` methods will have to support multiple databases.
- The `Message` model (in `django.contrib.auth`), its related manager in the `User` model (`user.message_set`), and the associated methods (`user.message_set.create()` and `user.get_and_delete_messages()`), will be removed. The [messages framework](#) should be used instead.

The related `messages` variable returned by the auth context processor will also be removed. Note that this means that the admin application will depend on the messages context processor.

- Authentication backends will need to support the `obj` parameter for permission checking. The `supports_object_permissions` attribute will no longer be checked and can be removed from custom backends.
- Authentication backends will need to support the `AnonymousUser` class being passed to all methods dealing with permissions. The `supports_anonymous_user` variable will no longer be checked and can be removed from custom backends.
- The ability to specify a callable template loader rather than a `Loader` class will be removed, as will the `load_template_source` functions that are included with the built in template loaders for backwards compatibility.
- `django.utils.translation.get_date_formats()` and `django.utils.translation.get_partial_date_formats()`. These functions will be removed; use the locale-aware `django.utils.formats.get_format()` to get the appropriate formats.
- In `django.forms.fields`, the constants: `DEFAULT_DATE_INPUT_FORMATS`, `DEFAULT_TIME_INPUT_FORMATS` and `DEFAULT_DATETIME_INPUT_FORMATS` will be removed. Use `django.utils.formats.get_format()` to get the appropriate formats.
- The ability to use a function-based test runner will be removed, along with the `django.test.simple.run_tests()` test runner.
- The `views.feed()` view and `feeds.Feed` class in `django.contrib.syndication` will be removed. The class-based view `views.Feed` should be used instead.
- `django.core.context_processors.auth`. This release will remove the old method in favor of the new method in `django.contrib.auth.context_processors.auth`.
- The `postgresql` database backend will be removed, use the `postgresql_psycopg2` backend instead.
- The `no` language code will be removed and has been replaced by the `nb` language code.
- Authentication backends will need to define the boolean attribute `supports_inactive_user` until version 1.5 when it will be assumed that all backends will handle inactive users.
- `django.db.models.fields.XMLField` will be removed. This was deprecated as part of the 1.3 release. An accelerated deprecation schedule has been used because the field hasn't performed any role beyond that of a simple `TextField` since the removal of `oldforms`. All uses of `XMLField` can be replaced with `TextField`.
- The undocumented `mixin` parameter to the `open()` method of `django.core.files.storage.Storage` (and subclasses) will be removed.

10.6.16 1.3

See the [Django 1.1 release notes](#) for more details on these changes.

- `AdminSite.root()`. This method of hooking up the admin URLs will be removed in favor of including `admin.site.urls`.
- Authentication backends need to define the boolean attributes `supports_object_permissions` and `supports_anonymous_user` until version 1.4, at which point it will be assumed that all backends will support these options.

10.7 The Django source code repository

When deploying a Django application into a real production environment, you will almost always want to use an [official packaged release of Django](#).

However, if you'd like to try out in-development code from an upcoming release or contribute to the development of Django, you'll need to obtain a clone of Django's source code repository.

This document covers the way the code repository is laid out and how to work with and find things in it.

10.7.1 High-level overview

The Django source code repository uses [Git](#) to track changes to the code over time, so you'll need a copy of the Git client (a program called `git`) on your computer, and you'll want to familiarize yourself with the basics of how Git works.

Git's website offers downloads for various operating systems. The site also contains vast amounts of [documentation](#).

The Django Git repository is located online at github.com/django/django. It contains the full source code for all Django releases, which you can browse online.

The Git repository includes several [branches](#):

- `main` contains the main in-development code which will become the next packaged release of Django. This is where most development activity is focused.
- `stable/A.B.x` are the branches where release preparation work happens. They are also used for bugfix and security releases which occur as necessary after the initial release of a feature version.

The Git repository also contains [tags](#). These are the exact revisions from which packaged Django releases were produced, since version 1.0.

A number of tags also exist under the `archive/` prefix for [archived work](#).

The source code for the [Djangoproject.com](https://DjangoProject.com) website can be found at github.com/django/djangoproject.com.

10.7.2 The main branch

If you'd like to try out the in-development code for the next release of Django, or if you'd like to contribute to Django by fixing bugs or developing new features, you'll want to get the code from the main branch.

Note: Prior to March 2021, the main branch was called `master`.

Note that this will get all of Django: in addition to the top-level `django` module containing Python code, you'll also get a copy of Django's documentation, test suite, packaging scripts and other miscellaneous bits. Django's code will be present in your clone as a directory named `django`.

To try out the in-development code with your own applications, place the directory containing your clone on your Python import path. Then `import` statements which look for Django will find the `django` module within your clone.

If you're going to be working on Django's code (say, to fix a bug or develop a new feature), you can probably stop reading here and move over to [the documentation for contributing to Django](#), which covers things like the preferred coding style and how to generate and submit a patch.

10.7.3 Stable branches

Django uses branches to prepare for releases of Django. Each major release series has its own stable branch.

These branches can be found in the repository as `stable/A.B.x` branches and will be created right after the first alpha is tagged.

For example, immediately after Django 1.5 alpha 1 was tagged, the branch `stable/1.5.x` was created and all further work on preparing the code for the final 1.5 release was done there.

These branches also provide bugfix and security support as described in [Supported versions](#).

For example, after the release of Django 1.5, the branch `stable/1.5.x` receives only fixes for security and critical stability bugs, which are eventually released as Django 1.5.1 and so on, `stable/1.4.x` receives only security and data loss fixes, and `stable/1.3.x` no longer receives any updates.

Historical information

This policy for handling `stable/A.B.x` branches was adopted starting with the Django 1.5 release cycle.

Previously, these branches weren't created until right after the releases and the stabilization work occurred on the main repository branch. Thus, no new feature development work for the next release of Django could be committed until the final release happened.

For example, shortly after the release of Django 1.3 the branch `stable/1.3.x` was created. Official support for that release has expired, and so it no longer receives direct maintenance from the Django project. How-

ever, that and all other similarly named branches continue to exist, and interested community members have occasionally used them to provide unofficial support for old Django releases.

10.7.4 Tags

Each Django release is tagged and signed by the releaser.

The tags can be found on GitHub's [tags](#) page.

Archived feature-development work

Historical information

Since Django moved to Git in 2012, anyone can clone the repository and create their own branches, alleviating the need for official branches in the source code repository.

The following section is mostly useful if you're exploring the repository's history, for example if you're trying to understand how some features were designed.

Feature-development branches tend by their nature to be temporary. Some produce successful features which are merged back into Django's main branch to become part of an official release, but others do not; in either case, there comes a time when the branch is no longer being actively worked on by any developer. At this point the branch is considered closed.

Django used to be maintained with the Subversion revision control system, that has no standard way of indicating this. As a workaround, branches of Django which are closed and no longer maintained were moved into `attic`.

A number of tags exist under the `archive/` prefix to maintain a reference to this and other work of historical interest.

The following tags under the `archive/attic/` prefix reference the tip of branches whose code eventually became part of Django itself:

- `boulder-oracle-sprint`: Added support for Oracle databases to Django's object-relational mapper. This has been part of Django since the 1.0 release.
- `gis`: Added support for geographic/spatial queries to Django's object-relational mapper. This has been part of Django since the 1.0 release, as the bundled application `django.contrib.gis`.
- `i18n`: Added [internationalization support](#) to Django. This has been part of Django since the 0.90 release.
- `magic-removal`: A major refactoring of both the internals and public APIs of Django's object-relational mapper. This has been part of Django since the 0.95 release.

- **multi-auth**: A refactoring of Django's bundled authentication framework which added support for authentication backends. This has been part of Django since the 0.95 release.
- **new-admin**: A refactoring of Django's bundled administrative application. This became part of Django as of the 0.91 release, but was superseded by another refactoring (see next listing) prior to the Django 1.0 release.
- **newforms-admin**: The second refactoring of Django's bundled administrative application. This became part of Django as of the 1.0 release, and is the basis of the current incarnation of `django.contrib.admin`.
- **queryset-refactor**: A refactoring of the internals of Django's object-relational mapper. This became part of Django as of the 1.0 release.
- **unicode**: A refactoring of Django's internals to consistently use Unicode-based strings in most places within Django and Django applications. This became part of Django as of the 1.0 release.

Additionally, the following tags under the `archive/attic/` prefix reference the tips of branches that were closed, but whose code was never merged into Django, and the features they aimed to implement were never finished:

- `full-history`
- `generic-auth`
- `multiple-db-support`
- `per-object-permissions`
- `schema-evolution`
- `schema-evolution-ng`
- `search-api`
- `sqlalchemy`

Finally, under the `archive/` prefix, the repository contains `soc20XX/<project>` tags referencing the tip of branches that were used by students who worked on Django during the 2009 and 2010 Google Summer of Code programs.

10.8 How is Django Formed?

This document explains how to release Django.

Please, keep these instructions up-to-date if you make changes! The point here is to be descriptive, not prescriptive, so feel free to streamline or otherwise make changes, but update this document accordingly!

10.8.1 Overview

There are three types of releases that you might need to make:

- Security releases: disclosing and fixing a vulnerability. This’ ll generally involve two or three simultaneous releases –e.g. 3.2.x, 4.0.x, and, depending on timing, perhaps a 4.1.x.
- Regular version releases: either a final release (e.g. 4.1) or a bugfix update (e.g. 4.1.1).
- Pre-releases: e.g. 4.2 alpha, beta, or rc.

The short version of the steps involved is:

1. If this is a security release, pre-notify the security distribution list one week before the actual release.
2. Proofread the release notes, looking for organization and writing errors. Draft a blog post and email announcement.
3. Update version numbers and create the release package(s).
4. Upload the package(s) to the `django project .com` server.
5. Upload the new version(s) to PyPI.
6. Declare the new version in the admin on `django project .com`.
7. Post the blog entry and send out the email announcements.
8. Update version numbers post-release.

There are a lot of details, so please read on.

10.8.2 Prerequisites

You’ ll need a few things before getting started:

- A GPG key. If the key you want to use is not your default signing key, you’ ll need to add `-u you@example.com` to every GPG signing command below, where `you@example.com` is the email address associated with the key you want to use.
- An install of some required Python packages:

```
$ python -m pip install wheel twine
```

- Access to Django’ s record on PyPI. Create a file with your credentials:

Listing 3: ~/.pypirc

```
[pypi]
username:YourUsername
password:YourPassword
```

- Access to the `djangoproject.com` server to upload files.
- Access to the admin on `djangoproject.com` as a “Site maintainer” .
- Access to post to `django-announce`.
- If this is a security release, access to the pre-notification distribution list.

If this is your first release, you’ ll need to coordinate with another releaser to get all these things lined up.

10.8.3 Pre-release tasks

A few items need to be taken care of before even beginning the release process. This stuff starts about a week before the release; most of it can be done any time leading up to the actual release:

1. If this is a security release, send out pre-notification one week before the release. The template for that email and a list of the recipients are in the private `django-security` GitHub wiki. BCC the pre-notification recipients. Sign the email with the key you’ ll use for the release and include [CVE IDs](#) (requested with Vendor: `djangoproject`, Product: `django`) and patches for each issue being fixed. Also, [notify django-announce](#) of the upcoming security release.
2. As the release approaches, watch Trac to make sure no release blockers are left for the upcoming release.
3. Check with the other mergers to make sure they don’ t have any uncommitted changes for the release.
4. Proofread the release notes, including looking at the online version to [catch any broken links](#) or reST errors, and make sure the release notes contain the correct date.
5. Double-check that the release notes mention deprecation timelines for any APIs noted as deprecated, and that they mention any changes in Python version support.
6. Double-check that the release notes index has a link to the notes for the new release; this will be in `docs/releases/index.txt`.
7. If this is a feature release, ensure translations from Transifex have been integrated. This is typically done by a separate translation’ s manager rather than the releaser, but here are the steps. Provided you have an account on Transifex:

```
$ python scripts/manage_translations.py fetch
```

and then commit the changed/added files (both `.po` and `.mo`). Sometimes there are validation errors which need to be debugged, so avoid doing this task immediately before a release is needed.

8. Update the `django-admin` manual page:

```
$ cd docs
$ make man
$ man _build/man/django-admin.1 # do a quick sanity check
$ cp _build/man/django-admin.1 man/django-admin.1
```

and then commit the changed man page.

9. If this is the alpha release of a new series, create a new stable branch from main. For example, when releasing Django 4.2:

```
$ git checkout -b stable/4.2.x origin/main
$ git push origin -u stable/4.2.x:stable/4.2.x
```

At the same time, update the `django_next_version` variable in `docs/conf.py` on the stable release branch to point to the new development version. For example, when creating `stable/4.2.x`, set `django_next_version` to `'5.0'` on the new branch.

10. If this is the “dot zero” release of a new series, create a new branch from the current stable branch in the [django-docs-translations](#) repository. For example, when releasing Django 4.2:

```
$ git checkout -b stable/4.2.x origin/stable/4.1.x
$ git push origin stable/4.2.x:stable/4.2.x
```

10.8.4 Preparing for release

Write the announcement blog post for the release. You can enter it into the admin at any time and mark it as inactive. Here are a few examples: [example security release announcement](#), [example regular release announcement](#), [example pre-release announcement](#).

10.8.5 Actually rolling the release

OK, this is the fun part, where we actually push out a release!

1. Check [Jenkins](#) is green for the version(s) you’re putting out. You probably shouldn’t issue a release until it’s green.
2. A release always begins from a release branch, so you should make sure you’re on a stable branch and up-to-date. For example:

```
$ git checkout stable/4.1.x
$ git pull
```

3. If this is a security release, merge the appropriate patches from `django-security`. Rebasing these patches as necessary to make each one a plain commit on the release branch rather than a merge commit. To ensure this, merge them with the `--ff-only` flag; for example:

```
$ git checkout stable/4.1.x
$ git merge --ff-only security/4.1.x
```

(This assumes `security/4.1.x` is a branch in the `django-security` repo containing the necessary security patches for the next release in the 4.1 series.)

If git refuses to merge with `--ff-only`, switch to the `security-patch` branch and rebase it on the branch you are about to merge it into (`git checkout security/4.1.x`; `git rebase stable/4.1.x`) and then switch back and do the merge. Make sure the commit message for each security fix explains that the commit is a security fix and that an announcement will follow ([example security commit](#)).

4. For a feature release, remove the `UNDER DEVELOPMENT` header at the top of the release notes and add the release date on the next line. For a patch release, remove the `Expected` prefix and update the release date, if necessary. Make this change on all branches where the release notes for a particular version are located.
5. Update the version number in `django/__init__.py` for the release. Please see [notes on setting the VERSION tuple](#) below for details on `VERSION`.
6. If this is a pre-release package, update the “Development Status” trove classifier in `setup.cfg` to reflect this. Otherwise, make sure the classifier is set to `Development Status :: 5 - Production/Stable`.
7. Tag the release using `git tag`. For example:

```
$ git tag --sign --message="Tag 4.1.1" 4.1.1
```

You can check your work by running `git tag --verify <tag>`.

8. Push your work, including the tag: `git push --tags`.
9. Make sure you have an absolutely clean tree by running `git clean -dfx`.
10. Run `make -f extras/Makefile` to generate the release packages. This will create the release packages in a `dist/` directory.
11. Generate the hashes of the release packages:

```
$ cd dist
$ md5sum *
$ sha1sum *
$ sha256sum *
```

12. Create a “checksums” file, `Django-<<VERSION>>.checksum.txt` containing the hashes and release information. Start with this template and insert the correct version, date, GPG key ID (from `gpg`

--list-keys --keyid-format LONG), release manager's GitHub username, release URL, and checksums:

This file contains MD5, SHA1, and SHA256 checksums for the source-code tarball and wheel files of Django <<VERSION>>, released <<DATE>>.

To use this file, you will need a working install of PGP or other compatible public-key encryption software. You will also need to have the Django release manager's public key in your keyring. This key has the ID ``XXXXXXXXXXXXXXXX`` and can be imported from the MIT keyserver, for example, if using the open-source GNU Privacy Guard implementation of PGP:

```
gpg --keyserver pgp.mit.edu --recv-key XXXXXXXXXXXXXXXXXXXX
```

or via the GitHub API:

```
curl https://github.com/<<RELEASE MANAGER GITHUB USERNAME>>.gpg | gpg --import -
```

Once the key is imported, verify this file:

```
gpg --verify <<THIS FILENAME>>
```

Once you have verified this file, you can use normal MD5, SHA1, or SHA256 checksumming applications to generate the checksums of the Django package and compare them to the checksums listed below.

Release packages

=====

<https://www.djangoproject.com/m/releases/<<MAJOR VERSION>>/<<RELEASE TAR.GZ FILENAME>>>

<https://www.djangoproject.com/m/releases/<<MAJOR VERSION>>/<<RELEASE WHL FILENAME>>>

MD5 checksums

=====

<<MD5SUM>> <<RELEASE TAR.GZ FILENAME>>

<<MD5SUM>> <<RELEASE WHL FILENAME>>

SHA1 checksums

=====

<<SHA1SUM>> <<RELEASE TAR.GZ FILENAME>>

<<SHA1SUM>> <<RELEASE WHL FILENAME>>

(continues on next page)

(continued from previous page)

```
SHA256 checksums
=====

<<SHA256SUM>>  <<RELEASE TAR.GZ FILENAME>>
<<SHA256SUM>>  <<RELEASE WHL FILENAME>>
```

13. Sign the checksum file (`gpg --clearsign --digest-algo SHA256 Django-<version>.checksum.txt`). This generates a signed document, `Django-<version>.checksum.txt.asc` which you can then verify using `gpg --verify Django-<version>.checksum.txt.asc`.

If you're issuing multiple releases, repeat these steps for each release.

10.8.6 Making the release(s) available to the public

Now you're ready to actually put the release out there. To do this:

1. Upload the release package(s) to the django project server, replacing A.B. with the appropriate version number, e.g. 4.1 for a 4.1.x release:

```
$ scp Django-* django project.com:/home/www/www/media/releases/A.B
```

If this is the alpha release of a new series, you will need to create the directory A.B.

2. Upload the checksum file(s):

```
$ scp Django-A.B.C.checksum.txt.asc django project.com:/home/www/www/media/pgp/Django-A.B.C.
↪checksum.txt
```

3. Test that the release packages install correctly using pip. Here's one method:

```
$ RELEASE_VERSION='4.1.1'
$ MAJOR_VERSION=`echo $RELEASE_VERSION | cut -c 1-3`

$ python -m venv django-pip
$ . django-pip/bin/activate
$ python -m pip install https://www.djangoproject.com/m/releases/$MAJOR_VERSION/Django-
↪$RELEASE_VERSION.tar.gz
$ deactivate
$ python -m venv django-pip-wheel
$ . django-pip-wheel/bin/activate
$ python -m pip install https://www.djangoproject.com/m/releases/$MAJOR_VERSION/Django-
↪$RELEASE_VERSION-py3-none-any.whl
$ deactivate
```

This just tests that the tarballs are available (i.e. redirects are up) and that they install correctly, but it'll catch silly mistakes.

4. Run the `confirm-release` build on Jenkins to verify the checksum file(s) (e.g. use `4.2rc1` for <https://media.djangoproject.com/pgp/Django-4.2rc1.checksum.txt>).
5. Upload the release packages to PyPI (for pre-releases, only upload the wheel file):

```
$ twine upload -s dist/*
```

6. Go to the [Add release page in the admin](#), enter the new release number exactly as it appears in the name of the tarball (`Django-<version>.tar.gz`). So for example enter “4.1.1” or “4.2rc1”, etc. If the release is part of an LTS branch, mark it so.

If this is the alpha release of a new series, also create a Release object for the final release, ensuring that the Release date field is blank, thus marking it as unreleased. For example, when creating the Release object for `4.2a1`, also create `4.2` with the Release date field blank.

7. Make the blog post announcing the release live.
8. For a new version release (e.g. 4.1, 4.2), update the default stable version of the docs by flipping the `is_default` flag to `True` on the appropriate `DocumentRelease` object in the `docs.djangoproject.com` database (this will automatically flip it to `False` for all others); you can do this using the site's admin.

Create new `DocumentRelease` objects for each language that has an entry for the previous release. Update `djangoproject.com`'s [robots.docs.txt](#) file by copying entries from `manage_translations.py` `robots_txt` from the current stable branch in the `django-docs-translations` repository. For example, when releasing Django 4.2:

```
$ git checkout stable/4.2.x
$ git pull
$ python manage_translations.py robots_txt
```

9. Post the release announcement to the [django-announce](#), [django-developers](#), [django-users](#) mailing lists, and the Django Forum. This should include a link to the announcement blog post.
10. If this is a security release, send a separate email to oss-security@lists.openwall.com. Provide a descriptive subject, for example, “Django” plus the issue title from the release notes (including CVE ID). The message body should include the vulnerability details, for example, the announcement blog post text. Include a link to the announcement blog post.
11. Add a link to the blog post in the topic of the `#django` IRC channel: `/msg chanserv TOPIC #django new topic goes here`.

10.8.7 Post-release

You're almost done! All that's left to do now is:

1. Update the `VERSION` tuple in `django/__init__.py` again, incrementing to whatever the next expected release will be. For example, after releasing 4.1.1, update `VERSION` to `VERSION = (4, 1, 2, 'alpha', 0)`.
2. Add the release in [Trac's versions list](#) if necessary (and make it the default by changing the `default_version` setting in the code.djangoproject.com's `trac.ini`, if it's a final release). The new X.Y version should be added after the alpha release and the default version should be updated after "dot zero" release.
3. If this was a security release, update [Archive of security issues](#) with details of the issues addressed.

10.8.8 New stable branch tasks

There are several items to do in the time following the creation of a new stable branch (often following an alpha release). Some of these tasks don't need to be done by the releaser.

1. Create a new `DocumentRelease` object in the `docs.djangoproject.com` database for the new version's docs, and update the `docs/fixtures/doc_releases.json` JSON fixture, so people without access to the production DB can still run an up-to-date copy of the docs site.
2. Create a stub release note for the new feature version. Use the stub from the previous feature release version or copy the contents from the previous feature version and delete most of the contents leaving only the headings.
3. Increase the default PBKDF2 iterations in `django.contrib.auth.hashers.PBKDF2PasswordHasher` by about 20% (pick a round number). Run the tests, and update the 3 failing hasher tests with the new values. Make sure this gets noted in the release notes (see the 4.1 release notes for an example).
4. Remove features that have reached the end of their deprecation cycle. Each removal should be done in a separate commit for clarity. In the commit message, add a "refs #XXXX" to the original ticket where the deprecation began if possible.
5. Remove `.. versionadded::`, `.. versionadded::`, and `.. deprecated::` annotations in the documentation from two releases ago. For example, in Django 4.2, notes for 4.0 will be removed.
6. Add the new branch to [Read the Docs](#). Since the automatically generated version names ("stable-A.B.x") differ from the version names used in Read the Docs ("A.B.x"), [create a ticket](#) requesting the new version.
7. [Request the new classifier on PyPI](#). For example `Framework :: Django :: 3.1`.

10.8.9 Notes on setting the VERSION tuple

Django’s version reporting is controlled by the VERSION tuple in `django/__init__.py`. This is a five-element tuple, whose elements are:

1. Major version.
2. Minor version.
3. Micro version.
4. Status –can be one of “alpha” , “beta” , “rc” or “final” .
5. Series number, for alpha/beta/RC packages which run in sequence (allowing, for example, “beta 1” , “beta 2” , etc.).

For a final release, the status is always “final” and the series number is always 0. A series number of 0 with an “alpha” status will be reported as “pre-alpha” .

Some examples:

- `(4, 1, 1, "final", 0) → “4.1.1”`
- `(4, 2, 0, "alpha", 0) → “4.2 pre-alpha”`
- `(4, 2, 0, "beta", 1) → “4.2 beta 1”`
